Abstract: In this note we investigate what is the best $L^p$-norm in order to describe the relation between the evolution of the state of a bilinear quantum system with the $L^p$-norm of the external field. Although $L^2$ has a structure more easy to handle, the $L^1$ norm is more suitable for this purpose. Indeed for every $p > 1$ it is possible to steer, with arbitrary precision, a generic bilinear quantum system from any eigenstate of the free Hamiltonian to any other with a control of arbitrary small $L^p$ norm. Explicit optimal costs for the $L^1$ norm are computed on an example.

Keywords: Bilinear systems, quantum systems, distributed parameters systems, optimal control, averaging control.

1. INTRODUCTION

1.1 Physical context

The state of a quantum system evolving on a Riemannian manifold $\Omega$, with associated measure $\mu$, is described by its wave function, that is, a point in the unit sphere of $L^2(\Omega, \mathbb{C})$. A system with wave function $\psi$ is in a subset $\omega$ of $\Omega$ with probability $\int_\omega |\psi|^2 d\mu$.

When submitted to an excitation by an external field (e.g. a laser) the time evolution of the wave function is governed by the bilinear Schrödinger equation

$$i \frac{\partial \psi}{\partial t} = -\Delta \psi + V(x)\psi(x,t) + u(t)W(x)\psi(x,t),$$

(1)

where $V, W : \Omega \to \mathbb{R}$ are real functions describing respectively the physical properties of the uncontrolled system and the external field, and $u : \mathbb{R} \to \mathbb{R}$ is a real function of the time representing the intensity of the latter.

1.2 Energy for a quantum system

Physically, the energy of a quantum system (1) with wave function $\psi$ is $E(\psi) = \int_{\Omega} [(-\Delta + V)\psi] \psi d\mu$. The energy is therefore constant in time whenever the control $u$ is zero. When the control $u$ is nonzero, and provided suitable regularity hypotheses, the energy evolves as

$$\frac{dE}{dt} = 2u(t)\Re \left( \int_{\Omega} [(\Delta + V)\psi] \psi d\mu \right).$$

(2)

Note that the time derivative of the energy $E$ at time $t$ depends on the value $u(t)$ of the intensity of the external field and on the wave function $\psi(t)$. Therefore a natural question is to find an a priori relation between the time evolution of the energy of system (1) and properties of the external field represented by $u$.

In particular we address the problem of finding a bound on the energy after the action of an external field. Namely, given an initial condition $\psi_0$ and a control $u : [0,T] \to \mathbb{R}$ denoting with $\psi$ the solution of (1) with $\psi(0) = \psi_0$ we look for bounds on the energy $E(T)$ in terms of the $L^p$ norm of $u$

$$\|u\|_{L^p(0,T)} = \left( \int_0^T |u(t)|^p dt \right)^{\frac{1}{p}},$$

(for some suitable $p > 0$) without computing explicitly the solution $t \in [0,T] \to \psi(t)$.

Many previous works addressed the problem of the optimal control of the system (1) for costs involving the $L^2$ norm of the control (see for instance Dahleh et al. (1990) or Grivopoulos and Bamieh (2008)). The main reason for the choice of the $L^2$ norm is the fact that the natural Hilbert structure of $L^2$ spaces allows to use the powerful tools of Hilbert optimization. It is sometimes believed that there is a natural relation of the $L^2$ norm of $u$ and the energy of the systems. This note presents a priori bounds on the $L^p$-norm of the control and shows that, in general, the $L^1$-norm provides more informations on the evolution of the system than other $L^p$-norms for $p > 1$. Most of the
2.2 Controllability results

Proposition 1. solution using the following continuity result.

We consider the evolution problem

\[ \frac{d\psi}{dt} = (A + u(t)B)\psi \]  

(3)

where \((A, B)\) satisfies the following assumption.

Assumption 1. \((A, B)\) is a pair of linear operators such that

(1) \(A\) is skew-adjoint and has purely discrete spectrum \((-i\lambda_k)_{k \in \mathbb{N}}\), the sequence \((\lambda_k)_{k \in \mathbb{N}}\) is positive non-decreasing and accumulates at \(-\infty\);

(2) \(B : H \rightarrow H\) is skew-adjoint and bounded.

In the rest of our study, we denote by \((\phi_k)_{k \in \mathbb{N}}\) an Hilbert basis of \(H\) such that \(A\phi_k = -i\lambda_k\phi_k\) for every \(k \in \mathbb{N}\). We denote by \(D(A + uB)\) the domain where \(A + uB\) is skew-adjoint.

From Assumption 1.2 together with Kato-Rellich Theorem, we deduce that \(A + uB\) is skew-adjoint with domain \(D(A)\). Moreover, for every constant \(u \in \mathbb{R}\), \(i(A + uB)\) is bounded from below.

Hence, for every initial condition \(\psi_0 \in H\), for every \(u\) piecewise constant, \(u : t \mapsto \sum_j u_j \chi(t, t_j + 1)(t)\), with \(0 = t_0 \leq t_1 \leq \ldots \leq t_{N+1}\) and \(u_0, \ldots, u_N\) in \(\mathbb{R}\), one can define the solution \(t \mapsto \mathcal{T}_{T}^u \psi_0\) of (3) by

\[
\mathcal{T}_{T}^u \psi_0 = e^{i(t-t_1)(A+u_{[1,N-1]}B)} \circ e^{i(t_1-t_2)(A+u_{[2,N-2]}B)} \circ \ldots \circ e^{i(u_{[N,N]}B)} \psi_0,
\]

for \(t \in [t_j, t_{j+1}]\). For a control \(u\) in \(L^1(\mathbb{R})\) we define the solution using the following continuity result.

Proposition 1. Let \(u\) and \((u_n)_{n \in \mathbb{N}}\) be in \(L^1(\mathbb{R})\). If for every \(t \in \mathbb{R}\) \(\int_0^t u_n(\tau) d\tau\) converges to \(\int_0^t u(\tau) d\tau\) as \(n\) tends to infinity, then, for every \(t \in \mathbb{R}\) and every \(\psi_0 \in H\), \((\mathcal{T}_{T}^{u_n} \psi_0)_{n \in \mathbb{N}}\) converges to \(\mathcal{T}_{T}^{u} \psi_0\) as \(n\) tends to infinity.

2.2 Controllability results

Considerable efforts have been made to study the controllability of (1). It is known (see Turinici (2000)) that exact controllability of (1) in \(H\) is hopeless in general. With the exception of some very particular examples where \(\Omega\) is one dimensional, (Beauchard and Laurent (2010)), no description of the attainable set is known. Therefore, we often consider the weaker notion of approximate controllability:

Definition 2. Let \((A, B)\) satisfy Assumption 1. The system \((A, B)\) is approximately controllable if, for every \(\psi_0, \psi_1\) in the unit Hilbert sphere, for every \(\varepsilon > 0\), there exists \(u_\varepsilon : [0, T_\varepsilon] \rightarrow \mathbb{R}\) such that \(\| \mathcal{T}_{T_\varepsilon}^{u_\varepsilon} \psi_0 - \psi_1 \| < \varepsilon\).

Various methods have been used to give criterion of approximate controllability of system (1). Nersesyan (2010), Beauchard and Mirrahimi (2009) and Mirrahimi (2009) rely on a Lyapunov approach. Boscaïn et al. (2012) adopt a more geometrical point of view, centered on the notion of non-degenerate (or non-resonant) transitions.

Definition 3. Let \((A, B)\) satisfy Assumption 1. A pair \((j, k)\) of integers is a non-degenerate transition of \((A, B)\) if (i) \(\langle \phi_j, B \phi_k \rangle \neq 0\) and (ii) for every \((l, m)\) in \(\mathbb{N}^2\), \(|\lambda_j - \lambda_k| = |l - m|\) implies \((j, k) = (l, m)\) or \(\langle \phi_l, B \phi_m \rangle = 0\) or \(\{j, k\} \cap \{l, m\} = \emptyset\).

Definition 4. Let \((A, B)\) satisfy Assumption 1. A subset \(S\) of \(\mathbb{N}^2\) is a non-degenerate chain of connectedness of \((A, B)\) if (i) for every \((j, k)\) in \(S\), \((j, k)\) is a non-degenerate transition of \((A, B)\) and (ii) for every \(r_a, r_b \in \mathbb{N}\), there exists a finite sequence \(r_a = r_{a_0}, r_1, \ldots, r_p = r_{b_0}\) in \(S\) such that, for every \(j \leq p - 1\), \((r_j, r_{j+1})\) belongs to \(S\).

The following sufficient criterion for approximate controllability is the central result of Boscaïn et al. (2012).

Proposition 5. Let \((A, B)\) satisfy Assumption 1. If \((A, B)\) admits a non-degenerate chain of connectedness, then \((A, B)\) is approximately controllable.

As proved by Mason and Sigalotti (2010) (see also Privat and Sigalotti (2010)), a system \((A, B)\) satisfying Assumption 1 generically admits a non-degenerate chain of connectedness. Hence, approximate controllability is a generic property for systems of the type (3) (see also Nersesyan (2010)).

In Boscaïn et al. (2012) an extensive (and in some case implicit) use of averaging results has been made. The following result is a generalization of the Rotating Wave Approximation to infinite dimensional systems and can be found in Chambon (2011).

Proposition 6. Let \((A, B)\) satisfy Assumption 1 and \((j, k)\) be a non-degenerate transition of \((A, B)\). Define \(T = 2\pi/|\lambda_j - \lambda_k|\) and \(\mathcal{N} = \{(l, m) \in \mathbb{N}^2|\langle \phi_l, B \phi_m \rangle \neq 0\} \setminus \{(j, k)\}\) and \(\mathcal{J}(j, k) = (j, k) \cap \{l, m\} = \emptyset\). Consider a \(T\)-periodic function \(u^* : \mathbb{R} \rightarrow \mathbb{R}\) satisfying

\[
\int_0^T u^*(t) e^{i(\lambda_j - \lambda_k) t} dt \neq 0 \quad \text{and} \quad \int_0^T u^*(t) e^{i(\lambda_j - \lambda_k) t} dt = 0 \quad \text{for every} \quad (l, m) \in \mathcal{N},
\]

Then there exist a sequence \((T_n^*)_{n \in \mathbb{N}}\) such that \(T_n^* \in (nT^* - T, nT^* + T)\) and \(\| \mathcal{T}_{T_n^*}^{u_n} \psi_0 - \psi_1 \| \rightarrow 0\) as \(n\) tends to infinity.
2.3 Formulation of an optimal control problem

Let \((A,B)\) satisfy Assumption 1 and admit a non-degenerate chain of connectedness. For every \(r > 0\), for every \(j, k \in \mathbb{N}\) and \(\varepsilon > 0\) we define \(\mathcal{A}_\varepsilon(j,k)\) as the set of functions \(u : [0,T] \rightarrow \mathcal{R} \) in \(L^r([0,T]) \cap L^r([0,T])\) such that \(\|\mathcal{T}_{\mathcal{U}}^k \phi_j - \phi_k\| < \varepsilon\). We consider the quantity
\[
C_r(\phi_j, \phi_k) = \sup_{\varepsilon > 0} \left( \inf_{u \in \mathcal{A}_\varepsilon(j,k)} \|u\|_{L^r([0,T])} \right).
\]
This quantity is the infimum of the \(L^r\)-norm of a control achieving approximate controllability. It clearly satisfies the triangle inequality. Next proposition states that \(C_r\) is a distance on the space of eigenlevels only when \(r = 1\). Its proof is given in Section 3.

Proposition 7. \(C_1\) is a distance on the set \(\{\phi_j, j \in \mathbb{N}\}\. For \(r > 1\), \(C_r\) is equal to zero on the set \(\{\phi_j, j \in \mathbb{N}\}\.\)

2.4 Weakly-coupled systems

Definition 1. Let \(k\) be a positive integer and let \((A,B)\) satisfy Assumption 1. Then \((A,B)\) is \(k\)-weakly-coupled if for every \(u_1 \in \mathcal{R}\), \(D(\|A + u_1B\|^{k/2}) = D(\|A\|^{k/2})\) and there exists a constant \(c_{|A,B|}\) such that, for every \(\psi\) in \(D(\|A\|)\), \(|\Re(\langle A^{k/2} \psi, B\psi \rangle| \leq c_{|A,B|}\).\)

The notion of weakly-coupled systems is closely related to the growth of the \(\|A\|^{k/2}\)-norm \(\langle A^{k/2} \psi, \psi \rangle\). For \(k = 1\), this quantity is the expected value of the energy of the system.

Proposition 8. (Boussaïd et al., 2011b, Proposition 2) Let \((A,B)\) be \(k\)-weakly-coupled. Then, for every \(\psi \in D(\|A\|^{k/2})\), \(K > 0\), \(T \geq 0\), and \(u \in L^1([0,\infty))\) for which \(\|u\|_{L^1} < K\), one has \(\|\mathcal{T}_{\mathcal{U}}^k \psi\|_{k/2} \leq e^{c_{|A,B|}K}\|\psi\|_{k/2}\).

For every \(N \in \mathbb{N}\), we define \(L_N\) the linear space spanned by \(\phi_1, \phi_2, \ldots, \phi_N\) and \(\pi_N : H \rightarrow H\), the orthogonal projection onto \(L_N\):
\[
\pi_N(\psi) = \sum_{k=1}^N (\phi_k, \psi)\phi_k.
\]

The compressions of order \(N\) of \(A\) and \(B\) are the finite rank operators \(A^{(N)} = \pi_N A \pi_N\) and \(B^{(N)} = \pi_N B \pi_N\). The Galerkin approximation of (3) at order \(N\) is the infinite dimensional system
\[
\frac{d}{dt} x = A^{(N)} x + u(t) B^{(N)} x.
\]

Since \(L_N\) is invariant by (4), one may also consider (4) as a finite-dimensional system, whose propagator is denoted by \(X_{\pi_N}^{(N)}(t,s)\).

Proposition 9. (Boussaïd et al., 2011b, Proposition 4) Let \(k\) and \(s\) be non-negative numbers with \(0 \leq s < k\). Let \((A,B)\) be \(k\)-weakly-coupled. Assume that there exists \(d > 0\), \(0 \leq r < k\) such that \(\|B\| \leq d\|\psi\|_{k/2}\) for every \(\psi\) in \(D(\|A\|^{k/2})\). Then for every \(\varepsilon > 0\), \(K > 0\), \(n \in \mathbb{N}\), and \((\psi_j)_{1 \leq j \leq n} \in D(\|A\|^{k/2})^n\) there exists \(N \in \mathbb{N}\) such that for every piecewise constant function \(u\)
\[
\|u\|_{L^n} < K \Rightarrow \left\| \mathcal{T}_{\mathcal{U}}^k \psi_j - X_{\pi_N}^{(N)}(t,0) \pi_N \psi_j \right\|_{k/2} < \varepsilon,
\]
for every \(t \geq 0\) and \(j = 1, \ldots, n\).

Remark 1. An interesting feature of Propositions 8 and 9 is the fact that the bound of the \(\|A\|^{k/2}\) norm of the solution of (3) or the bound on the error between the infinite dimensional system and its finite dimensional approximation only depend on the \(L^1\) norm of the control, not on the time.

3. PROOF OF PROPOSITION 7

3.1 Lower bounds for the \(L^1\) norm

Proposition 10. Let \((A,B)\) satisfy Assumption 1. For every \(j, k \in \mathbb{N}\) such that \(B \phi_j \neq 0\), for every locally integrable \(u : [0,T] \rightarrow \mathcal{R}\),
\[
\|u\|_{L^1([0,T])} \geq \frac{|\langle \phi_j, B\phi_k \rangle|}{\|B\phi_j\|}.
\]
Proof: Let \(j, k \in \mathbb{N}\). For every locally integrable \(u : [0,T] \rightarrow \mathcal{R}\), define \(y : u \mapsto e^{-At} B u\phi_j\). For almost every \(t\), \(y\) is differentiable with respect to \(t\) and \(\frac{dy}{dt} = u(t)e^{-At} B e^{At}\). In particular,
\[
\left| \frac{\dot{\phi}_j}{\|\dot{\phi}_j\|} \right| \leq \|u(t)\|\|B\phi_j\|.
\]
This concludes the proof of Proposition 10. \(\Box\)

A consequence of Proposition 10 is that \(C_1(\phi_j, \phi_k)\) is bounded away from zero as soon as \(j \neq k\).

3.2 Upper bound for the \(L^1\) norm

In order to give an upper bound for \(C_1(\phi_j, \phi_k)\) when \((j,k)\) is a non-degenerate transition of \((A,B)\), we come back to Proposition 6. In the case where \(\mathcal{N}\) is finite, Boscain et al. (2012) give an explicit construction of a piecewise constant \(u^*\) with value in \([0,1]\) and satisfying the assumptions of Proposition 6 such that, for every \(n \in \mathbb{N}\),
\[
\left\| \frac{u^*}{n} \right\|_{L^1([0,T])} \leq \frac{5\pi}{4\|B\phi_k\|}.
\]
More details about the choice of \(u^*\) when \((A,B)\) is weakly-coupled are given by (Boussaïd et al., 2011a, Section III-C). Let us just mention that the choice \(u^* : t \mapsto \cos(|\lambda_j - \lambda(k)|\) guarantees
\[
\left\| \frac{u^*}{n} \right\|_{L^1([0,T])} \leq \frac{2}{\|B\phi_k\|}
\]
for every \(n \in \mathbb{N}\).

In any case, \((A,B)\) being weakly-coupled or not, this guarantees that, for every \(j, k \in \mathbb{N}\), \(C_1(\phi_j, \phi_k) < +\infty\).

The fact that \(C_1\) is symmetric is a consequence of the so-called time reversibility of (3): the propagator associated with \((-A,-B)\) is the adjoint of the backward propagator associated with \((A,B)\). This proves that \(C_1\) is a distance on the set \(\{\phi_j, j \in \mathbb{N}\}\).

3.3 \(L^r\) norms with \(r > 1\)

Proposition 11. Let \((A,B)\) satisfy Assumption 1 and admit a non-degenerate chain of connectedness. If \(r > 1\), then for every \(j, k \in \mathbb{N}\), \(C_r(\phi_j, \phi_k) = 0\).
Proof: It is enough to consider \((j,k)\) in a non-degenerate chain of connectedness of \((A,B)\). The result is then a consequence of Proposition 6, since, for every \(n \in \mathbb{N}\),
\[
\left\|\frac{u^n}{n}\right\|_{L^1(0,T)}^2 \leq \frac{1}{n^2} \int_0^T |u^n(t)|^2 \, dt \\
\leq \frac{1}{n^2} \int_0^{nT+T} |u^n(t)|^2 \, dt \\
\leq \frac{1}{n} \int_0^{n(T/2 + 2)} |u^n(t)|^2 \, dt,
\]
which tends to zero as \(n\) tends to infinity. \(\square\)

4. ROTATION OF A PLANAR MOLECULE

In this Section, we apply our results to the well studied example of the rotation of a planar molecule (see, for instance, Salomon and Turinici (2005); Boscain et al. (2009, 2012)).

4.1 Presentation of the model

We consider a linear molecule with fixed length and center of mass. We assume that the molecule is constrained to stay in a fixed plane and that its only degree of freedom is the rotation, in the plane, around its center of mass. The state of the system at time \(t\) is described by a point \(\theta \mapsto \psi(t,\theta)\) of \(L^2(\Omega,\mathbb{C})\) where \(\Omega = \mathbb{R}/2\pi\mathbb{Z}\) is the one dimensional torus. The Schrödinger equation writes
\[
\frac{\partial \psi}{\partial t}(t,\theta) = -\Delta \psi(t,\theta) + u(t) \cos(\theta) \psi(t,\theta),
\]
where \(\Delta\) is the Laplace-Beltrami operator on \(\Omega\). The self-adjoint operator \(-\Delta\) has purely discrete spectrum \(\{k^2, k \in \mathbb{N}\}\). All its eigenvalues are double but zero which is simple. The eigenvalue zero is associated with the constant functions. The eigenvalue \(k^2\) for \(k > 0\) is associated with the two eigenfunctions \(\theta \mapsto \frac{1}{\sqrt{\pi}} \cos(k\theta)\) and \(\theta \mapsto \frac{1}{\sqrt{\pi}} \sin(k\theta)\). The Hilbert space \(H = L^2(\Omega,\mathbb{C})\) splits in two subspaces \(H_e\) and \(H_o\), the spaces of even and odd functions of \(\Omega\) respectively. The spaces \(H_e\) and \(H_o\) are invariant under the dynamics of (5), hence no global controllability is to be expected in \(H\).

We focus on the space \(H_o\). The restriction \(A\) of \(i\Delta\) to \(H_o\) is skew adjoint, with simple eigenvalues \((-ik^2)\) associated with the eigenvectors \(\phi_k : \theta \mapsto \frac{1}{\sqrt{\pi}} \sin(k\theta)\) \(k \in \mathbb{N}\).

The restriction \(B\) of \(\psi \mapsto -i \cos(\theta)\psi\) to \(H_o\) is skew-adjoint and bounded. The pair \((A,B)\) satisfies Assumption 1 and is weakly-coupled (see (Boussaid et al., 2011b, Section III.C)).

The Galerkin approximations of \(A\) and \(B\) of order \(N\) are
\[
A^{(N)} = \begin{pmatrix}
i & 0 & \cdots & 0 \\
0 & 4i & \cdots & \vdots \\
\vdots & \ddots & \ddots & 0 \\
0 & \cdots & 0 & N^2i
\end{pmatrix}
\text{ and } B^{(N)} = -i \begin{pmatrix}0 & 1/2 & 0 & \cdots & 0 \\
1/2 & 0 & 1/2 & \cdots & \vdots \\
0 & \cdots & 0 & \cdots & 0 \\
\vdots & \cdots & 1/2 & 0 & 1/2 \\
0 & \cdots & 0 & 1/2 & 0\end{pmatrix}.
\]

4.2 Computation of \(C_1(\phi_1,\phi_2)\)

Our aim is to compute the minimal \(L^1\) norm needed to approximately transfer the wave function from the first eigenspace to the second one. Precisely, we will prove Proposition 12. \(C_1(\phi_1,\phi_2) = \pi\).

Proof: The transition (1, 2) is non-degenerate. Proposition 6 applies with \(N = \emptyset\). For every \(\eta\) in \((0, 1)\), we define \(u^\eta\), the \(2\pi/3\) periodic function defined by
\[
\begin{cases}
u^\eta(x) = 1 & \text{for } 0 < x < \eta \\
u^\eta(x) = 0 & \text{for } \eta \leq x \leq 2\pi/3.
\end{cases}
\]

Proposition 6 states that, defining
\[
T^* = \frac{\pi^2}{\sin^2(\frac{\pi}{2})},
\]
there exists a sequence \((T_n)_{n \in \mathbb{N}}\) such that \(T_n \in (nT^* - 2\pi/3, nT^* + 2\pi/3)\) and \(|(\phi_2,T_n^{u^\eta/\eta}\phi_1)|\) tends to one as \(n\) tends to infinity.

One computes, for every \(n \in \mathbb{N}\),
\[
\left\|\frac{u^\eta}{n}\right\|_{L^1(0,T)} \leq \frac{\eta}{\sin^2(\frac{\pi}{2})} \frac{3\pi}{2}.
\]
This last quantity tends to \(\pi\) as \(\eta\) tends to zero. This proves that \(C_1(\phi_1,\phi_2) \leq \pi\).

For every locally integrable control \(u\), we define \(y_1 : t \mapsto (\phi_1,T^*_n\phi_1)\) and \(y_2 : t \mapsto (\phi_2,T^*_n\phi_1)\). The function \(t \mapsto |y_1(t)|^2\) is absolutely continuous, and, for almost every \(t\),
\[
\frac{d}{dt} |y_1(t)|^2 = 2\Re(y_1(t)^* \dot{y}_1(t)) = u(t)\Re(y_2(t) \dot{y}_1(t)).
\]

Hence,
\[
\frac{d}{dt} |y_1(t)|^2 \leq |y_2(t)| \|u(t)\| |u(t)|,
\]
or
\[
-\|u(t)\| \leq \frac{d}{dt} |y_1(t)|^2 \leq \frac{4}{|y_1(T)|^2 - 1} \leq \|u\|_{L^1(0,T)}.
\]
Integrating between 0 and \(T\), one gets
\[
2 \arctan\left(\frac{1}{|y_1(T)|^2 - 1}\right) \leq \|u\|_{L^1(0,T)}.
\]
and, provided \(\|u\|_{L^1(0,T)} < \pi\),
\[
\sqrt{\frac{1}{|y_1(T)|^2 - 1}} \leq \tan\left(\frac{\|u\|_{L^1(0,T)}}{2}\right).
\]
Finally, \(|y_2(T)| \geq \frac{|y_1(T)|^2 \leq \sin\left(\frac{\|u\|_{L^1(0,T)}}{2}\right)}{2}\).
If \( (u_n)_{n \in \mathbb{N}} \) is a sequence of locally integrable functions and \( (T_n)_{n \in \mathbb{N}} \) is a sequence of positive numbers such that \( |\langle \phi_2, Y_{T_n}^u \phi_1 \rangle| \) tends to one, then \( \liminf_n \| u_n \|_{L^1(0,T_n)} \geq \pi \), hence \( C_1(\phi_1, \phi_2) \geq \pi \). This concludes the proof of Proposition 12.

5. CONCLUSION AND PERSPECTIVES

5.1 Conclusion

We introduced an optimal control problem associated with a bilinear quantum system. For \( p \geq 1 \), we have given some estimates of the \( L^p \) norm of the control needed to steer the system from an eigenstate of the free Hamiltonian to another. In particular, for generic bilinear quantum systems, it is possible to steer any eigenstate of the free Hamiltonian to any neighborhood of any other eigenstate with arbitrary small \( L^2 \) norm of the control.

5.2 Future works

The estimates given for the \( L^1 \) norm only depend on the control potential \( B \) (and not on the eigenvalues of the free Hamiltonian \( A \) as long as the transition stay non-degenerate). It is possible that \( L^p \) costs, with \( p < 1 \), are physically more relevant. A new approach would be needed to study this case since our methods do not provide any information about the \( L^p \) norm of the control needed to steer an energy level to another in the case \( p < 1 \).
