Lower estimates for the expected Betti numbers of random real hypersurfaces

Damien Gayet, Jean-Yves Welschinger

March 12, 2013

Abstract

We estimate from below the expected Betti numbers of real hypersurfaces taken at random in a smooth real projective $n$-dimensional manifold. These random hypersurfaces are chosen in the linear system of a large $d$-th power of a real ample line bundle equipped with a Hermitian metric of positive curvature. As for the upper bounds that we recently established, these lower bounds read as a product of a constant which only depends on the dimension $n$ of the manifold with the Kählerian volume of its real locus $\mathbb{R}X$ and $\sqrt{d^n}$. Actually, any closed affine real algebraic hypersurface appears with positive probability as part of such random real hypersurfaces in any ball of $\mathbb{R}X$ of radius $O(\frac{1}{\sqrt{d^n}})$.

Keywords: Real projective manifold, ample line bundle, random polynomial, Betti numbers

1 Introduction

What is the topology of a real hypersurface taken at random in a smooth real projective manifold? When the latter is the projective line, this question reduces to: how many real roots does a random real polynomial in one variable have? This question was answered by M. Kac [8] in 1943 and for a different measure, by E. Kostlan [9] and M. Shub and S. Smale [13] in the early 90’s. In our recent paper [5] (see also [6]) we did bound from above the expected Betti numbers of such random real hypersurfaces in smooth real projective manifolds. Our purpose now is to bound these Betti numbers from below, see Corollary 1.0.3.

Let us first recall our framework. We denote by $X$ a smooth complex projective manifold of positive dimension $n$ defined over the reals, by $c_X : X \to X$ the induced Galois antiholomorphic involution and by $\mathbb{R}X = \text{Fix}(c_X)$ the real locus of $X$ which we implicitly assume to be non-empty. We then consider an ample line bundle $L$ over $X$, also defined over the reals. It comes thus equipped with an antiholomorphic involution $c_L : L \to L$ which turns the bundle projection map $\pi : L \to X$ into a $\mathbb{Z}/2\mathbb{Z}$-equivariant one, so that $c_X \circ \pi = \pi \circ c_L$. We equip $L$ in addition with a real Hermitian metric $h$, thus invariant under $c_L$, which has a positive curvature form $\omega$ – locally defined by $\omega = \frac{1}{2\pi} \partial \overline{\partial} \log h(e,e)$ for any non-vanishing local holomorphic section $e$ of $L$. This metric induces a Kähler metric $g_h = \omega(\cdot, \cdot, i\cdot)$ on $X$, which reduces
to a Riemannian metric \( g_h \) on \( \mathbb{R}X \). It then induces a \( L^2 \)-scalar product on every space of global holomorphic real sections of tensor products \( L^d \) of \( L, d > 0 \), which are denoted by

\[
\mathbb{R}H^0(X, L^d) = \{ \sigma \in H^0(X, L^d) \mid c_L \circ \sigma = \sigma \circ c_X \}.
\]

This \( L^2 \)-scalar product is defined by the formula

\[
\forall (\sigma, \tau) \in \mathbb{R}H^0(X, L^d), \quad \langle \sigma, \tau \rangle = \int_X h(\sigma, \tau)(x)dx,
\]

where \( dx \) denotes any volume form of \( X \). For instance, \( dx \) can be chosen to be the normalized volume form \( dV_h = \frac{1}{\sqrt{\pi}} e^{-\|x\|^2} dx \). This \( L^2 \)-scalar product finally induces a Gaussian probability measure \( \mu_{\mathbb{R}} \) on \( \mathbb{R}H^0(X, L^d) \) whose density with respect to the Lebesgue one at \( \sigma \in \mathbb{R}H^0(X, L^d) \) writes \( \frac{1}{\sqrt{\pi}} e^{-\|\sigma\|^2} \), where \( N_d = \dim H^0(X, L^d) \). It is with respect to this probability measure that we consider random real hypersurfaces (as in the works [9] and [13]) and our results hold for large values of \( d \).

Let us recall the estimates from above that we recently established in [5]. For every \( d > 0 \), we denote by \( \mathbb{R}\Delta_d \) the discriminant locus of sections \( \sigma \in \mathbb{R}H^0(X, L^d) \) which do not vanish transversally. For every \( \sigma \in \mathbb{R}H^0(X, L^d) \setminus \mathbb{R}\Delta_d \), we denote by \( \mathbb{R}C_\sigma = \sigma^{-1}(0) \cap \mathbb{R}X \) its smooth real vanishing locus. Then, for every \( i \in \{0, \ldots, n-1\} \), we denote by \( m_i(\mathbb{R}C_\sigma) \) the \( i \)-th Morse number of \( \mathbb{R}C_\sigma \) and by \( b_i(\mathbb{R}C_\sigma) \) its \( i \)-th Betti number with real coefficients. These are defined as the infimum over all Morse functions \( f \) on \( \mathbb{R}C_\sigma \) of the number of critical points of index \( i \) of \( f \) and as \( b_i(\mathbb{R}C_\sigma) = \dim H_i(\mathbb{R}C_\sigma; \mathbb{R}) \) respectively. It follows from Morse theory that \( b_i(\mathbb{R}C_\sigma) \leq m_i(\mathbb{R}C_\sigma) \) and we set

\[
E(b_i) = \int_{\mathbb{R}H^0(X, L^d) \setminus \mathbb{R}\Delta_d} b_i(\mathbb{R}C_\sigma)d\mu_{\mathbb{R}}(\sigma)
\]

and \( E(m_i) = \int_{\mathbb{R}H^0(X, L^d) \setminus \mathbb{R}\Delta_d} m_i(\mathbb{R}C_\sigma)d\mu_{\mathbb{R}}(\sigma) \). Then, we proved

**Theorem 1.0.1 (Theorem 1 of [5])** Let \( X \) be a smooth real projective manifold of positive dimension \( n \) and \( (L, h) \) be a real holomorphic Hermitian line bundle of positive curvature over \( X \). Then, for every \( i \in \{0, \cdots, n-1\} \),

\[
\limsup_{d \to \infty} \frac{1}{\sqrt{d}} E(m_i) \leq \frac{1}{\sqrt{\pi}} e_{\mathbb{R}}(i, n-1-i) \text{Vol}_h(X).
\]

In Theorem 1.0.1, \( \text{Vol}_h(X) \) denotes the total Riemannian volume of the real locus \( \mathbb{R}X \) for the Kähler metric \( g_h \), while \( e_{\mathbb{R}}(i, n-1-i) \) is a constant which only depends on \( i \) and the dimension of \( X \). The latter originates from random symmetric matrices and is defined as

\[
e_{\mathbb{R}}(i, n-1-i) = \int_{\text{Sym}(i, n-1-i, \mathbb{R})} |\det A|d\mu_{\mathbb{R}}(A),
\]

where \( \text{Sym}(i, n-1-i, \mathbb{R}) \) denotes the open cone of non-degenerated real symmetric matrices of size \( n-1 \) and signature \( (i, n-1-i) \), while \( d\mu_{\mathbb{R}} \) is the restriction to this cone of the classical Gaussian probability measure of the space of symmetric matrices,
see [5]. In particular, for fixed \( i \geq 0 \), there exists \( c_i > 0 \) such that for large values of \( n \),

\[
e_R(i, n - 1 - i) \leq \exp(-c_i n^2),
\]

as follows from some large deviation estimates established in [1], see Theorem 1.6 of [5].

Our aim now is to get similar asymptotic estimates from below for the expected Betti numbers of random real hypersurfaces linearly equivalent to \( L^d \), see Corollary 1.0.3. These estimates will follow from our main result, Theorem 1.0.2, which we now formulate.

Let \( \Sigma \) be a closed hypersurface of \( \mathbb{R}^n \), which we do not assume to be connected. For every \( \sigma \in R^\mathcal{H}_0(X, L^d) \setminus \mathbb{R} \Delta_d \), we denote by \( N_\Sigma(\sigma) \) the maximal number of disjoint open subsets of \( \mathbb{R} X \) having the property that each such open subset \( U' \) contains a hypersurface \( \Sigma' \subset \mathbb{R} C_\sigma \) and \((U', \Sigma')\) is diffeomorphic to \((\mathbb{R}^n, \Sigma)\). We then set

\[
E(N_\Sigma) = \int_{R^\mathcal{H}_0(X, L^d) \setminus \mathbb{R} \Delta_d} N_\Sigma(\sigma) d\mu_\mathcal{H}(\sigma)
\]

and we associate to \( \Sigma \), in fact to its isotopy class in \( \mathbb{R}^n \), a positive constant \( c_\Sigma \) out of the amount of transversality of a real polynomial \( P \) in \( n \) variables which vanishes along a hypersurface isotopic to \( \Sigma \), see (8). Our main result is:

**Theorem 1.0.2** Let \( X \) be a smooth real projective manifold of positive dimension \( n \) and \((L, h)\) be a real holomorphic Hermitian line bundle of positive curvature over \( X \). Let \( \Sigma \) be a closed hypersurface of \( \mathbb{R}^n \), which does not need to be connected. Then,

\[
\liminf_{d \to \infty} \frac{1}{\sqrt{d}} E(N_\Sigma) \geq c_\Sigma \text{Vol}_h(\mathbb{R}X).
\]

In particular, when \( \Sigma \) is connected, Theorem 1.0.2 bounds from below the expected number of connected components that are diffeomorphic to \( \Sigma \) in the real vanishing locus of a random section \( \sigma \in \mathbb{R}^\mathcal{H}_0(X, L^d) \). As in Theorem 1.0.1, the constant \( c_\Sigma \) does not depend on the choice of the triple \((X, L, h)\), it only depends on \( \Sigma \).

Let us now denote, for every positive integer \( n \), by \( \mathcal{H}_n \) the set of diffeomorphism classes of smooth closed connected hypersurfaces in \( \mathbb{R}^n \). For every \( i \in \{0, \cdots, n-1\} \) and every \( \Sigma \in \mathcal{H}_n \), we denote by \( b_i(\Sigma) = \dim H_i(\Sigma; \mathbb{R}) \) its \( i \)-th Betti number with real coefficients and by \( m_i(\Sigma) \) its \( i \)-th Morse number.

**Corollary 1.0.3** Let \( X \) be a smooth real projective manifold of positive dimension \( n \) and \((L, h)\) be a real holomorphic Hermitian line bundle of positive curvature over \( X \). Then, for every \( i \in \{0, \cdots, n-1\} \),

\[
\liminf_{d \to \infty} \frac{1}{\sqrt{d}} E(b_i) \geq \left( \sum_{\Sigma \in \mathcal{H}_n} c_\Sigma b_i(\Sigma) \right) \text{Vol}_h(\mathbb{R}X)
\]

and likewise \( \liminf_{d \to \infty} \frac{1}{\sqrt{d}} E(m_i) \geq \left( \sum_{\Sigma \in \mathcal{H}_n} c_\Sigma m_i(\Sigma) \right) \text{Vol}_h(\mathbb{R}X) \). In particular, for every \( i \in \{0, \cdots, n-1\} \),

\[
\liminf_{d \to \infty} \frac{1}{\sqrt{d}} E(b_i) \geq \exp \left( -2e^{\gamma_0 n} \right) \text{Vol}_h(\mathbb{R}X).
\]
The last part of Corollary 1.0.3 follows from the fact that for every $i \in \{0, \cdots, n-1\}$, $\mathbb{R}^n$ contains the product of spheres $S^i \times S^{n-1-i}$ as a hypersurface, while $c_{S^i \times S^{n-1-i}} \geq \exp \left( -2e^{70n} \right)$, see Proposition 2.3.3. This double exponential decay has to be compared with (2) and is not an optimal bound. For instance, it follows from Theorem 1 of [5] that when $n = 1$, $\frac{1}{\sqrt{d}} E(b_0)$ converges to $\frac{1}{\sqrt{2}} \text{Length}_h(\mathbb{R}X)$. The results given by Theorem 1.0.1 and Theorem 1.0.2 raise the following question: does the quotient $E(b_i)/\text{Vol}_h(\mathbb{R}X)^{1/d}$ or likewise $E(m_i)/\text{Vol}_h(\mathbb{R}X)^{1/d}$ have a limit in general, which only depends on $i \in \{0, \cdots, n-1\}$ and the dimension $n$ of $X$, but not on the triple $(X, L, h)$? This holds true for $n = 1$, see Theorem 1 of [5] or also Theorem 2 of [5] for similar results on the number of critical points of given index.

Note that another natural Gaussian probability measure could have been chosen on $\mathbb{R}H^0(X, L^d)$, induced by a $L^2$-product defined by integration over $\mathbb{R}X$ instead of the integration over $X$ (see §3.1.1 of [6] for a discussion on our choice and other possible ones). This is the measure considered by F. Nazarov and M. Sodin in their study of random spherical harmonics in dimension two, see [12], and more recently by A. Lerario and E. Lundberg in higher dimensions, see [10]. The upper and lower estimates they obtain for the number of connected components for these spherical harmonics are in $d^n$ instead of $\sqrt{d^n}$. These estimates are also established for homogeneous polynomials on unit spheres in [10]. Note that such a behaviour was previously guessed through computational experiments by C. Raffalli, while P. Sarnak and I. Wigman informed us that they were able to prove the upper estimates in $\mathbb{R}P^2$.

In order to prove Theorem 1.0.2, we follow the same probability approach as Nazarov and Sodin (see §6.1 of [12] or also §2.2 of [10]) which we combine with the $L^2$-estimates of Hörmander, see §3.1. The latter make it possible asymptotically to produce, for every smooth closed hypersurface $\Sigma$ of $\mathbb{R}^n$ contained in a ball of radius $R$ and every ball $B_d$ of $\mathbb{R}X$ of radius $R/\sqrt{d}$, a section $\sigma \in \mathbb{R}H^0(X, L_d)$ which vanishes transversally in $B_d$ along a hypersurface diffeomorphic to $\Sigma$, the transversality being quantitative in the sense of S. Donaldson, see Definition 7 in [3] and Proposition 3.1.4. We then bound from above the expected $C^1$-norm of sections of $\mathbb{R}H^0(X, L^d)$ in such a ball $B_d$ and deduce from Markov’s inequality that a random section in $\mathbb{R}H^0(X, L^d)$ vanishes with positive probability in $B_d$ along a hypersurface diffeomorphic to $\Sigma$, see Proposition 3.3.1. The result follows from the fact that there are more or less $\text{Vol}_h(\mathbb{R}X)/\sqrt{d^n}$ disjoint such balls in $\mathbb{R}X$. Recall that the construction in [4] of real Donaldson hypersurfaces with many spheres in their real locus was carried out in a similar manner.

The first part of the paper is devoted to preliminaries on closed affine real algebraic hypersurfaces and the second one to the proofs of Theorem 1.0.2 and Corollary 1.0.3.

Aknowledgements. The research leading to these results has received funding from the European Community’s Seventh Framework Progamme ([FP7/2007-2013] [FP7/2007-2011]) under grant agreement n° [258204].
2 Closed affine real algebraic hypersurfaces

This paragraph is devoted to preliminaries. We first introduce two real functions which play a role in the proof of Theorem 1.0.2. Then, we associate a positive constant \( c_\Sigma \) to any isotopy class of smooth closed hypersurface \( \Sigma \) of \( \mathbb{R}^n \), see (8), using a notion of regular pair given by Definition 2.2.2. Finally, we estimate from below this constant in the case of product of spheres, see §2.3.

2.1 Two real functions

We introduce here two real functions \( f_\tau \) and \( g_R \) whose maximum and minimum turn out to play a role in the proof of Theorem 1.0.2. For every \( \tau > 0 \), we set

\[
f_\tau : a \in [\sqrt{\tau}, +\infty[ \mapsto \frac{1}{\sqrt{\pi}} (1 - \frac{\tau}{a^2}) \int_a^{+\infty} e^{-t^2} dt,
\]

so that \( f_\tau(\sqrt{\tau}) = \lim_{a \to \infty} f_\tau = 0 \). We define

\[
m_\tau = \sup_{[\sqrt{\tau}, +\infty[} f_\tau.
\]

In particular, for every positive \( \tau \),

\[
m_\tau \geq f_\tau(\sqrt{\tau} + 1) \geq \frac{1}{\sqrt{\pi}(\tau + 1)} e^{-(\sqrt{\tau} + 1)^2}.
\]

The estimate (4) is chosen in the light of the following Lemma 2.1.1

**Lemma 2.1.1** For every positive \( \tau \), the function \( f_\tau \) reaches its maximum on the interval \( [\sqrt{\tau}, \sqrt{\tau} + 1] \).

**Proof.** For every positive \( \tau \) and every \( a \geq \sqrt{\tau} \),

\[
f_\tau'(a) = \frac{1}{\sqrt{\pi}} \left( \frac{2}{\tau a^3} \int_a^{+\infty} e^{-t^2} dt - (1 - \frac{\tau}{a^2}) e^{-a^2} \right),
\]

so that if \( f_\tau \) reaches its maximum at the point \( c \in [\sqrt{\tau}, +\infty[ \),

\[
\frac{2}{\tau c^3} \int_c^{+\infty} e^{-t^2} dt = (1 - \frac{\tau}{c^2}) e^{-c^2}.
\]

Now \( \int_c^{+\infty} e^{-t^2} dt \leq e^{-c^2} \), so that \( (1 - \frac{\tau}{c^2}) \leq \frac{1}{c^2} \) and \( c^2 - \tau \leq \frac{1}{c^2} \leq 1 \). Hence \( c \leq \sqrt{1 + \tau} \). \( \Box \)

Likewise, for every positive \( R \) and every positive integer \( n \), we set

\[
g_R : s \in \mathbb{R}^n_+ \mapsto \frac{(R + s)^{2n}}{s^{2n}} e^{\pi(R + s)^2},
\]

so that \( \lim_{s \to 0} g_R(s) = \lim_{s \to +\infty} g_R(s) = +\infty \). We define

\[
\rho_R = \inf_{\mathbb{R}^n_+} g_R.
\]

In particular, for every positive \( R \),

\[
\rho_R \leq g_R(R) = 4^n \exp(4\pi R^2).
\]
2.2 Real polynomials and transversality

We introduce here the notion of regular pair, see Definition 2.2.2, and the constant $c_{\Sigma}$ associated to any isotopy class of smooth closed hypersurface $\Sigma$ of $\mathbb{R}^n$, see (8).

**Lemma 2.2.1** If $P = \sum_{(i_1, \ldots, i_n) \in \mathbb{N}^n} a_{i_1, \ldots, i_n} z_1^{i_1} \cdots z_n^{i_n} \in \mathbb{R}[X_1, \ldots, X_n]$, then

$$\|P\|^2_{L^2} = \int_{\mathbb{C}^n} |P(z)|^2 e^{-\|z\|^2} \, dz = \sum_{(i_1, \ldots, i_n) \in \mathbb{N}^n} |a_{i_1, \ldots, i_n}|^2 \frac{i_1! \cdots i_n!}{\pi^{n+i_1+\cdots+i_n}}.$$

**Proof.** We note that $\|P\|^2_{L^2} = \sum_{I \in \mathbb{N}^n} a_{I} \overline{a_{I}} \int_{\mathbb{C}^n} z^I \overline{z}^I e^{-\|z\|^2} \, dz$. But for every $k \neq 0$, $\int_{\mathbb{C}} z^k e^{-|z|^2} \, dz = \int_{\mathbb{C}} z^k e^{-|z|^2} \, dz = 0$, whereas for every non-negative $k$,

$$\int_{\mathbb{C}} |z|^{2k} e^{-|z|^2} \, dz = 2\pi \int_{0}^{+\infty} r^{2k+1} e^{-\pi r^2} \, dr = \pi \int_{0}^{+\infty} t^{k} e^{-\pi t} \, dt = \frac{1}{\pi^k} \Gamma(k+1) = \frac{k!}{\pi^k}.$$

The result follows then from Fubini’s Theorem. □

**Definition 2.2.2** Let $U$ be a bounded open subset of $\mathbb{R}^n$ and $P \in \mathbb{R}[X_1, \ldots, X_n]$, $n > 0$. The pair $(U, P)$ is said to be regular if and only if

1. zero is a regular value of the restriction of $P$ to $U$,
2. the vanishing locus of $P$ in $U$ is compact.

**Definition 2.2.3** For every regular pair $(U, P)$ given by Definition 2.2.2, we denote by $T(U, P)$ the set of $(\delta, \epsilon) \in (\mathbb{R}^+)^2$ such that

1. there exists a compact subset $K$ of $U$ satisfying $\inf_{U \setminus K} |P| > \delta$,
2. for every $y \in U$, $|P(y)| < \delta \Rightarrow \|d_y P\| > \epsilon$, where $\|d_y P\|^2 = \sum_{i=1}^{n} |\partial P/\partial x_i|^2$.

We then set for every regular pair $(U, P)$, $R_{(U, P)} = \max(1, \sup_{y \in U} \|y\|)$ and

$$\tau_{(U, P)} = 2\rho_{R_{(U, P)}} \|P\|^2_{L^2} \inf_{(\delta, \epsilon) \in T(U, P)} \left( \frac{1}{\delta^2} + \frac{\pi n}{\epsilon^2} \right) \in \mathbb{R}^*,$$

(7)

where $\rho_{R_{(U, P)}}$ is defined by (5).

Now, let $\Sigma$ be a closed hypersurface of $\mathbb{R}^n$, not necessarily connected. We denote by $T_{\Sigma}$ the set of regular pairs $(U, P)$ given by Definition 2.2.2, such that the vanishing locus of $P$ in $U$ contains a subset isotopic to $\Sigma$ in $\mathbb{R}^n$. It follows from Nash’s Theorem for hypersurfaces in $\mathbb{R}^n$ that $T_{\Sigma}$ is non empty, see [11]. We then set

$$c_{\Sigma} = \sup_{(U, P) \in T_{\Sigma}} \left( \frac{m_{\tau_{(U, P)}}}{2^n \text{Vol}(B(R_{(U, P)}))} \right),$$

(8)

where $m_{\tau_{(U, P)}}$ is defined by (3) and $\text{Vol}(B(R_{(U, P)}))$ denotes the volume of the Euclidean ball of radius $R_{(U, P)}$ in $\mathbb{R}^n$. From (4) follows that for every $(U, P) \in T_{\Sigma}$,

$$c_{\Sigma} \geq \frac{\left\lfloor \frac{n}{2} \right\rfloor ! \exp \left( - (\sqrt{\tau_{(U, P)}} + 1)^2 \right)}{2^{n+1} \pi (\frac{n}{2})^n R_{(U, P)}^n (1 + \tau_{(U, P)}) \sqrt{n}}.$$

(9)
since the volume of the ball of radius \( R_{(U,P)} \) in \( \mathbb{R}^n \) is bounded from below by \( \frac{2n+1}{\sqrt{n!}} R_{(U,P)}^n \) for every \( n > 0 \). For large values of \( \tau_{(U,P)} \), as the ones which appear in the examples given in §2.3, we deduce from (9) that

\[
c_S \geq \exp(-2\tau_{(U,P)}). \tag{10}
\]

2.3 Examples

2.3.1 The spheres

**Proposition 2.3.1** For every positive integer \( n \), \( c_{S^{n-1}} \geq \exp(-2e^{43n}) \).

For every \( n > 0 \), we set \( P_S(x_1, \ldots, x_n) = \sum_{j=1}^n x_j^2 - \sqrt{n} - 1 \) and \( U_S = \{(x_1, \ldots, x_n) \in \mathbb{R}^n | \sum_{j=1}^n x_j^2 < \sqrt{n} + 2\} \). The pair \((U_S, P_S)\) is regular in the sense of Definition 2.2.2 and \( P_S^{-1}(0) \subset U_S \) is isotopic in \( \mathbb{R}^n \) to the unit sphere \( S^{n-1} \).

**Lemma 2.3.2** For every \( n > 0 \) and every \( 0 < \delta < 1 \), \((\delta, 2\sqrt{n} + 1 - \delta) \in \mathcal{T}_{(U_S,P_S)}\).

**Proof.** For every \( x \in \mathbb{R}^n \) and \( \delta > 0 \),

\[
|P_S(x)| < \delta \Leftrightarrow \sqrt{n} + 1 - \delta < \|x\|^2 < \sqrt{n} + 1 + \delta
\]

\[
\Rightarrow \|d_x P_S\|^2 = 4\|x\|^2 > 4(\sqrt{n} + 1 - \delta).
\]

Moreover, when \( 0 < \delta < 1 \), \( K_\delta = \{x \in U | \sqrt{n} + 1 - \delta \leq \|x\|^2 \leq \sqrt{n} + 1 + \delta\} \) is compact in \( U_S \). We deduce that \((\delta, \epsilon) \in \mathcal{T}_{(U_S,P_S)}\) for \( \epsilon^2 = 4(\sqrt{n} + 1 - \delta) \). \( \square \)

**Proof of Proposition 2.3.1.** For every positive integer \( n \), \( R_{(U_S,P_S)}^2 = \sqrt{n} + 2 \), while from Lemma 2.2.1, \( \|P_S\|^2_{L^2} = (\sqrt{n} + 1)^2 + \frac{2n}{\pi} \leq 5n \). From (7) and Lemma 2.3.2, we deduce

\[
\tau_{(U_S,P_S)} \leq \rho_{R_{(U_S,P_S)}} 10n(1 + \frac{\pi \sqrt{n}}{4})
\]

\[
\leq \exp \left( n \ln 4 + 4 \pi (\sqrt{n} + 2) + \ln \left( 10n + \frac{\pi \sqrt{n}}{4} \right) \right) \text{ by (6)}
\]

\[
\leq \exp(43n).
\]

The estimate \( c_{S^{n-1}} \geq \exp(-2e^{43n}) \) follows then from (10). \( \square \)

2.3.2 Products of spheres

**Proposition 2.3.3** For every positive integer \( n \) and every \( 0 \leq i \leq n-1 \), \( c_{S^i \times S^{n-1-i}} \geq \exp(-2e^{70n}) \).

For every \( n > 0 \) and every \( 0 \leq i \leq n-1 \), we set

\[
Q_i((x_1, \ldots, x_{i+1}), (y_1, \ldots, y_{n-i-1})) = \left( \sum_{j=1}^{i+1} x_j^2 - 2 \right)^2 + \sum_{j=1}^{n-i-1} y_j^2 - 1
\]

and \( U_{Q_i} = \{(x, y) \in \mathbb{R}^{i+1} \times \mathbb{R}^{n-i} | \|x\|^2 + \|y\|^2 < 5\} \). The pair \((U_{Q_i}, Q_i)\) is regular in the sense of Definition 2.2.2 and \( Q_i^{-1}(0) \subset V_{Q_i} \) is isotopic in \( \mathbb{R}^n \) to the product \( S^i \times S^{n-1-i} \) of the unit spheres in \( \mathbb{R}^{i+1} \) and \( \mathbb{R}^{n-i} \).
Lemma 2.3.4 For every positive integer $n$ and every $0 \leq i \leq n - 1$,

$\left(\frac{1}{2\sqrt{n}}, \frac{1}{2}\right) \cap \left(1 - \frac{1}{2\sqrt{n}}\right) \in T(U_{Q_i}, Q_i)$.

Proof. For every $(x, y) \in \mathbb{R}^{i+1} \times \mathbb{R}^{n-i-1}$ and every $0 < \delta < \frac{1}{2}$,

$|Q_i(x, y)| < \delta \iff 1 - \delta < (|x|^2 - 2)^2 + |y|^2 < 1 + \delta$

$\Rightarrow \|d_{(x,y)}Q_i\|^2 = 4|y|^2 + 16|x|^2(|x|^2 - 2)^2$

with $|x|^2 > 2 - \sqrt{1 + \delta} > 1/2$. Thus, $\|d_{(x,y)}Q_i\|^2 > 4((|x|^2 - 2)^2 + |y|^2) > 4(1 - \delta)$

and we deduce the result by choosing $\delta = \frac{1}{2\sqrt{n}}$. $\square$

Proof of Proposition 2.3.3. For every positive integer $n$ and every $0 \leq i \leq n - 1$, $R^2_{(U_{Q_i}, Q_i)} = 5$, $\rho_{R_{(U_{Q_i}, Q_i)}} \leq 4^n \exp(20\pi)$ by (6), while from Lemma 2.2.1,

$\|Q_i\|^2_{L^2} = 9 + \frac{2}{\pi^2}(n - i - 1) + \frac{32}{\pi^2}(i + 1) + \frac{24}{\pi^4}(i + 1) + \frac{16}{\pi^4}\left(\frac{i + 1}{2}\right) \leq 13n^2$.

We deduce from (7) and Lemma 2.3.4 the upper estimate $\tau_{(U_{Q_i}, Q_i)} \leq 156n^34^n \exp(20\pi) \leq e^{70\pi}$ since $\ln n \leq n - 1$. We then deduce from (10) the lower estimate $c_{S^1 \times S^{n-i-1}} \geq \exp(-2e^{70\pi})$. $\square$

Remark 2.3.5 The lower estimates given by Propositions 2.3.1 and 2.3.3 are far from being optimal.

3 Lower bounds for the Betti numbers of random real algebraic hypersurfaces

We first implement the affine real algebraic hypersurfaces in every smooth real projective manifold at the scale $1/\sqrt{d}$ thanks to Hörmander $L^2$-estimates, see Proposition 3.1.4. We then follow the approach of F. Nazarov and M. Sodin (see [12] or also [10]) by first estimating the expected local $C^1$-norm of sections, see Proposition 3.2.1, and then deducing a positive probability of presence of such affine real algebraic hypersurfaces in the vanishing locus of random sections in any ball of radius $O(\frac{1}{\sqrt{d}})$, see Proposition 3.3.1. Theorem 1.0.2 and Corollary 1.0.3 follow.

3.1 Hörmander sections

Definition 3.1.1 Let $(X, c_X)$ be a smooth real projective manifold of positive dimension $n$ and $(L, h, c_L)$ be a real holomorphic Hermitian line bundle of positive curvature over $X$. For every $x$ in $\mathbb{R}X$, let us call a $h$-trivialization of $L$ in the neighbourhood of $x$ the following data:

1. a local holomorphic chart $\psi_x : (W_x, x) \subset X \to (V_x, 0) \subset \mathbb{C}^n$ such that

(a) $\psi_x \circ c_X = \text{conj} \circ \psi_x$, where $\text{conj} : (y_1, \cdots, y_n) \in \mathbb{C}^n \mapsto (\bar{y}_1, \cdots, \bar{y}_n) \in \mathbb{C}^n$
We can thus choose a $h$-trivialization near every point $x$ of $X$. The plurisubharmonic function $\tilde{\phi} = -\log h(e, e)$ takes real values. Its composition $\tilde{\phi} \circ \psi^{-1}_x$ writes $\tilde{\phi} \circ \psi^{-1}_x = \Re \phi_1 + \phi_2$, where $\phi_1 \in \mathbb{C}[y_1, \ldots, y_n]$ is a degree two polynomial and $\phi_2(y) = \pi \|y\|^2 + O(\|y\|^3)$, since the Hermitian part of the second derivative of $\tilde{\phi}$ at $x$ is $\pi g_h$ by definition. We then set, following [7], $e = \exp(\phi_1 \circ \psi^{-1}_x)\tilde{e}$ which satisfies the second condition of Definition 3.1.1 after restricting the open subset $W_x$ if necessary.

How small has to be chosen $W_x$ depends on the higher order derivatives of $\phi_2$. However, these higher order derivatives are the same as the ones of $\tilde{\phi} \circ \psi^{-1}_x$ since they are not affected by $\phi_1$. Now, we can cover $\mathbb{R}X$ with the supports of finitely many real sections $\tilde{e}_1, \ldots, \tilde{e}_k$. The derivative of these sections are uniformly bounded over $\mathbb{R}X$. We can thus choose a $h$-trivialization near every point $x$ of $\mathbb{R}X$ in such a way that the open subset $V_x$ of $\mathbb{C}^n$ does not depend on $x \in \mathbb{R}X$. Restricting $V_x$ if necessary, this ensures the existence of a field of $h$-trivializations on $\mathbb{R}X$.

For every positive $d$ and every $\sigma \in \mathbb{R}H^0(X, L^d)$, $\|\sigma\|_{L^2(h)}$ denotes the $L^2$-norm for the normalized volume form induced by the Kähler form $\omega$, that is

$$\|\sigma\|_{L^2(h)}^2 = \int_X \|\sigma\|_{h^d}^2 dV_h,$$
where $dV_h = \frac{\omega^n}{f_x^2}$. Moreover, if the restriction of $\sigma$ to $W_x$ writes $\sigma = f_x e^d$ for some holomorphic $f_x : W_x \to \mathbb{C}$, we set $|\sigma| = |f_x|$ so that on $W_x$, $\|\sigma\|_{\hat{h}_d}^2 = |\sigma|^2 \exp(-d\phi)$, and for every $z$ in $W_x$,

$$|d_z \sigma| = |d_y (f_x \circ \psi_x^{-1})|$$

where $y = \psi_x(z)$. (12)

We also denote, for every small enough $R > 0$, by $B(x, R) \subset W_x$ the ball centered at $x$ and of radius $R$ for the flat metric of $V$ pulled back by $\psi_x$, so that $B(x, R) = \psi_x^{-1}(B(0, R))$. We finally denote by $\delta_L = \int_X c_1(L)^n$ the degree of the bundle $L$ and recall that the notion of regular pair has been defined in Definition 2.2.2.

**Proposition 3.1.4** Let $X$ be a smooth real projective manifold of positive dimension $n$ and $(L, h)$ be a real holomorphic Hermitian line bundle with positive curvature over $X$. We choose a field of $h$-trivializations on $\mathbb{R} X$. Then, for every regular pair $(U, P)$, every large enough integer $d$ and every $x$ in $\mathbb{R} X$, there exist $\sigma_{(U,P)} \in \mathbb{R} H^0(X, L^d)$ and an open subset $U_d \subset B(x, \frac{R_{U,P}}{\sqrt{d}})$ such that

1. $\|\sigma_{(U,P)}\|_{L^2(h)}$ be equivalent to $\frac{\|P\|_{\hat{h}_d}}{\sqrt{d}}$ as $d$ grows to infinity
2. $(U_d, \sigma_{(U,P)}^{-1}(0) \cap U_d)$ be diffeomorphic to $(U, P^{-1}(0) \cap U) \subset \mathbb{R}^n$
3. for every $(\delta, \epsilon) \in \mathcal{T}_{(U,P)}$ given by Definition 2.2.3, there exists a compact subset $K_d \subset U_d$ such that

$$\inf_{U_d \setminus K_d} |\sigma_{(U,P)}| > \frac{\delta}{2} \sqrt{d}^a,$$

while for every $y$ in $U_d$,

$$|\sigma_{(U,P)}(y)| < \frac{\delta}{2} \sqrt{d}^a \Rightarrow |d_y \sigma_{(U,P)}| > \frac{\epsilon}{2} \sqrt{d}^{a+1}.$$ (13)

Recall that the norm of the derivative is given by (12), and note that the quantitative transversality condition (13) is the one used by Donaldson in [3].

Under the hypotheses of Proposition 3.1.4, let $x \in \mathbb{R} X$. We set, for every large enough $d$, $U_d = \psi_x^{-1}(\frac{1}{\sqrt{d}} U) \subset B(x, \frac{R_{U,P}}{\sqrt{d}})$. Let $\chi : \mathbb{C}^n \to [0, 1]$ be a smooth function with compact support in $V$ which equals one in a neighbourhood of the origin. Then, let $\sigma$ be the global smooth section of $L_d$ defined by $\sigma_{(x \setminus W_x)} = 0$ and

$$\sigma_{|W_x} = (\chi \circ \psi_x) P(\sqrt{d} \psi_x) e^d.$$ From the $L^2$-estimates of Hörmander, see [7], [14], [15], there exists a global section $\tau$ of $L_d$ such that $\bar{\partial} \tau = \bar{\partial} \sigma$ and $\|\tau\|_{L^2(h)} \leq \|\bar{\partial} \sigma\|_{L^2(h)}$ for $d$ large enough. This section can be chosen orthogonal to the holomorphic sections and is then unique, in particular real, so that $c_{1,d} \circ \tau \circ c_X = \tau$. Moreover,

**Lemma 3.1.5** There exist positive constants $c_1$ and $c_2$ which do not depend on $x \in \mathbb{R} X$ and satisfy $\|\tau\|_{L^2(h)} \leq c_1 e^{-c_2d}$ as well as $|\tau|_{C^1(U_d)} \leq c_1 e^{-c_2d}$, where the $C^1$-norm is defined by (12).
Proof. The $L^2$-estimates of Hörmander read for large enough $d$

\[
\|\tau\|_{L^2(h)}^2 \leq \int_X \|ar{\partial} \sigma\|^2 dV_h = \int_{W_x} |\psi_x^* \delta \chi|^2 |P(\sqrt{d} \psi_x)|^2 e^{-d\phi} dV_h
\]

\[
\leq \epsilon^{\deg(P)} \sup_{V} \left( |\bar{\partial} \chi|^2 \left| \frac{P(\sqrt{d} \cdot)}{\sqrt{d}^{\deg P}} \right|^2 \right) e^{-d \inf_{supp(\bar{\partial} \chi)} (\phi \psi_x^{-1})}
\]

so that there exist positive constants $c_1, \tilde{c}_2$, not depending on $x$, such that $\|\tau\|_{L^2(h)} \leq c_1 \exp(-\tilde{c}_2 d)$. Now, since $\tau \circ \psi_x^{-1}$ is holomorphic on $\chi^{-1}(1)$, the mean value inequality for plurisubharmonic functions implies that for every $z$ in $U_d$,

\[
|\tau(z)|^2 \leq \frac{1}{\text{Vol}(B\left(\frac{1}{\sqrt{d}}\right))} \int_{B(\psi_x(z), \frac{1}{\sqrt{d}})} |\tau \circ \psi_x^{-1}(y)|^2 dy
\]

\[
\leq \frac{1}{\text{Vol}(B\left(\frac{1}{\sqrt{d}}\right))} \int_{B(z, \frac{1}{\sqrt{d}})} \|\tau\|_{L^2(h)}^2 e^{d\phi} \psi_x^* dy
\]

\[
\leq \frac{1}{\text{Vol}(B\left(\frac{1}{\sqrt{d}}\right))} \sup_{B(z, \frac{1}{\sqrt{d}})} (e^{d\phi} |\det d_{\bar{\partial}} \psi_x|) \|\tau\|_{L^2(h)}^2,
\]

where the determinant $|\det d_{\bar{\partial}} \psi_x|$ is computed with respect to the volume forms $dV_h$ and $dy$. We deduce that there exists a constant $c_3$ not depending on $x \in \mathbb{R}X$ such that $|\tau|^2 \leq c_3 d^n e^{-2\tilde{c}_2 d}$ on $U_d$, see (11) and Definition 3.1.2. The estimate for $|d \tau|$ is proved along the same lines. □

Proof of Proposition 3.1.4. We set $\sigma_{(U,P)} = \sqrt{d^i} (\sigma - \tau)$ and $K_d = \psi_x^{-1}(\frac{1}{\sqrt{d}} K)$, see Definition 2.2.3. The section $\sigma_{(U,P)}$ is global and holomorphic. Lemma 3.1.5 shows that on $U_d$, $\sigma_{(U,P)}$ is a small perturbation of $\sqrt{d} \sigma$. In particular,

\[
\|\sigma_{(U,P)}\|_{L^2(h)} \sim \int_{\chi^{-1}(1)} |P(\sqrt{d} y)|^2 e^{-d\phi(y)} dy \delta L \rightarrow \frac{\|P\|^2_{L^2}}{\delta L}
\]

Moreover, for every pair $(\delta, \epsilon) \in \mathcal{T}(U,P)$ and every $z \in U_d \setminus K_d$,

\[
\left| \frac{1}{\sqrt{d}} \sigma_{(U,P)}(z) \right| = |\sigma(z) - \tau(z)| \quad (17)
\]

\[
\geq |\sigma(z)| - \sup_{B\left(\frac{R_{(U,P)}}{\sqrt{d}}\right)} |\tau| \quad (18)
\]

\[
\geq |P(\sqrt{d} \psi_x(z))| - \sup_{B\left(\frac{R_{(U,P)}}{\sqrt{d}}\right)} |\tau| \quad (19)
\]

\[
> \delta - \sup_{B\left(\frac{R_{(U,P)}}{\sqrt{d}}\right)} |\tau| \quad \text{from Definition 2.2.3.} \quad (20)
\]
Thus, by Lemma 3.1.5, if $d$ is large enough, $\inf_{u_d \backslash K_d} |\sigma(u, p)| > \frac{\delta}{2} \sqrt{d}$ whenever $x \in \mathbb{R}X$. Moreover, for every $z \in U_d$,
\[
|\sigma(u, p)(z)| < \frac{\delta}{2} \sqrt{d} \quad \Rightarrow \quad |\sigma(z) - \tau(z)| < \frac{\delta}{2}
\]
\[
\Rightarrow \quad |\sigma(z)| < \frac{\delta}{2} + |\tau(z)|
\]
\[
\Rightarrow \quad |P(\sqrt{d}\psi)(z)| < \delta
\]
for $d$ large enough, whatever $x \in \mathbb{R}X$ is. Thus,
\[
|\sigma(u, p)(z)| < \frac{\delta}{2} \sqrt{d} \quad \Rightarrow \quad |d\sqrt{d}_x(z)p| > \epsilon
\]
\[
\Rightarrow \quad |d_{xz}\sigma| > \epsilon \sqrt{d} \text{ using notation (12)}
\]
\[
\Rightarrow \quad |d_{xz}\sigma(u, p)| > \frac{\epsilon}{2} \sqrt{d}^{n+1}
\]
for $d$ large enough by Lemma 3.1.5. Finally, Lemma 3.1.5 together with Lemma 3.1.6 imply that $(\sigma^{-1}(U, p)(0) \cap U_d)$ is isotopic to $(\sigma^{-1}(0) \cap U_d)$ and so diffeomorphic to $(P^{-1}(0) \cap U)$ when $d$ is large enough. \(\square\)

**Lemma 3.1.6** Let $U$ be an open subset of $\mathbb{R}^n$, $f : U \to \mathbb{R}$ be a function of class $C^1$ and $(\epsilon, \epsilon) \in (\mathbb{R}_+)^2$ be such that

1. there exists a compact subset $K$ of $U$ such that $\inf_{U \backslash K} |f| > \delta$,
2. for every $y$ in $U$, $|f(y)| < \delta \Rightarrow |df(y)| > \epsilon$.

Then, for every function $g : U \to \mathbb{R}$ of class $C^1$ such that $\sup U |g| < \delta$ and $\sup U |dg| < \epsilon$, zero is a regular value of $f + g$ and $(f + g)^{-1}(0)$ is compact and isotopic to $f^{-1}(0)$ in $U$.

**Proof.** For every $t \in [0, 1]$ and every $y \in U$,
\[
f + tg(y) = 0 \Rightarrow |f(y)| = |tg(y)| < \delta.
\]
The point $y$ is then contained in $K$ and $|df(y)| > \epsilon$. Hence, we have
\[
|d_y(f + tg)| \geq |d_yf| - |td_yg| > 0,
\]
so that 0 is a regular value of $f + tg$. The hypersurface $\Sigma_t = (f + tg)^{-1}(0)$ is smooth and included in $K$ from the implicit function Theorem. It produces an isotopy between $f^{-1}(0)$ and $(f + g)^{-1}(0)$. \(\square\)

### 3.2 The expected local $C^1$-norm of sections

The following Proposition 3.2.1 computes the expected local $C^1$-norm of sections. It is inspired by an analogous result of F. Nazarov and M. Sodin, see [12] (or also [10]). Recall that we denote by $\delta_L$ the degree $\int_X c_1(L)^n$ of the line bundle $L$ over $X$, that $\cdot$ denotes the modulus evaluated in the charts given by $h$-trivializations, see (12), and that the constant $\rho_R$ is defined by (5). Finally, we denote by $v$ the density of $dV_h$ with respect to the volume form $dx$ chosen in (1) to define the $L^2$-product, so that $dV_h = v(x)dx$. 

12
Proposition 3.2.1 Let $X$ be a smooth real projective manifold of positive dimension $n$ and $(L, h)$ be a real holomorphic Hermitian line bundle of positive curvature over $X$. We equip $\mathbb{R}X$ with a field of $h$-trivializations. Then, for every positive $R$,

$$\limsup_{d \to \infty} \sup_{x \in \mathbb{R}X} \frac{1}{d^n} E\left( \sup_{B(x, \frac{R}{\sqrt{d}})} \frac{|\sigma|^2}{v(x)} \right) \leq \frac{1}{2} \delta_L \rho_R$$

$$\limsup_{d \to \infty} \sup_{x \in \mathbb{R}X} \frac{1}{d^{n+1}} E\left( \sup_{B(x, \frac{R}{\sqrt{d}})} \frac{|d\sigma|^2}{v(x)} \right) \leq \frac{1}{2} \pi n \delta_L \rho_R.$$

Proof. Let $R > 0$, $x \in \mathbb{R}X$ and $W_x$ be a neighbourhood given by the $h$-trivialization. When $d$ is large enough, $B(x, R/\sqrt{d}) \subset W_x$ and $\phi \circ \psi^{-1}_x(y) = \pi \|y\|^2 + o(\|y\|^2)$. We deduce from the mean value inequality that for every $s \in \mathbb{R}_+$ and $\sigma \in \mathcal{H}^0(X, L^d)$,

$$\forall z \in B(x, \frac{R}{\sqrt{d}}), \ |\sigma(z)|^2 \leq \frac{1}{\text{Vol}(B(\frac{R}{\sqrt{d}}))} \int_{B(z, \frac{R}{\sqrt{d}})} |\sigma|^2 \psi^*_x dy$$

$$\leq \frac{1}{\text{Vol}(B(\frac{R}{\sqrt{d}}))} \int_{B(x, \frac{R+n}{\sqrt{d}})} |\sigma|^2 \psi^*_x dy.$$

Thus, $\sup_{B(x, \frac{R}{\sqrt{d}})} |\sigma|^2 \leq \frac{1}{\text{Vol}(B(\frac{R}{\sqrt{d}}))} \int_{B(x, \frac{R+n}{\sqrt{d}})} |\sigma|^2 \psi^*_x dy$ and after exchange of the integrals,

$$E\left( \sup_{B(x, \frac{R}{\sqrt{d}})} |\sigma|^2 \right) \leq \frac{1}{\text{Vol}(B(\frac{R}{\sqrt{d}}))} \int_{B(x, \frac{R+n}{\sqrt{d}})} E(|\sigma|^2) \psi^*_x dy.$$

Then, let $z \in B(x, \frac{R+n}{\sqrt{d}})$ and $\sigma_0 \in \mathcal{H}^0(X, L^d)$ be the Bergman section at $z$. Its norm equals one and it is orthogonal to the space of sections vanishing at $z$. Assume for the moment that the volume form $dx$ chosen to define the $L^2$-scalar product equals $dV_h$, so that $v = 1$. Then, from Lemma 2.2 of [15] (see also [2], [6]),

$$\|\sigma_0(z)\|_{\mathcal{H}^0}^2 \sim \delta_L d^n.$$

But $\|\sigma_0(z)\|_{\mathcal{H}^0}^2 = |\sigma_0(z)|^2 e^{-\delta h(z)}$, from which we deduce

$$|\sigma_0(z)|^2 \leq \delta_L d^n e^{\pi(R+s)^2} + o(d^n),$$

where the $o(d^n)$ can be chosen not to depend on $x \in \mathbb{R}X$. As a consequence,

$$E(|\sigma(z)|^2) = \int_{\mathcal{H}^0(X, L^d)} |\sigma(z)|^2 d\mu_\mathbb{R}(\sigma) = |\sigma_0(z)|^2 \frac{1}{\sqrt{\pi}} \int_{\mathbb{R}} a^2 e^{-a^2} da$$

$$\leq \frac{1}{2} \delta_L d^n e^{\pi(R+s)^2} + o(d^n),$$

and finally,

$$\sup_{x \in \mathbb{R}X} E\left( \sup_{B(x, \frac{R}{\sqrt{d}})} |\sigma|^2 \right) \leq \frac{\delta_L d^n}{2 \text{Vol}(B(\frac{R}{\sqrt{d}}))} \int_{B(0, \frac{R+n}{\sqrt{d}})} e^{\pi(R+s)^2} dy + o(d^n)$$

$$\leq \frac{1}{2} \delta_L d^n e^{\pi(R+s)^2} \frac{(R+s)^{2n}}{s^{2n}} + o(d^n).$$
Choosing $s \in \mathbb{R}^+_+$ such that $g_R(s) = \rho_R$, see (5), we deduce that
\[
\limsup_{d \to \infty} \sup_{x \in \mathbb{R}^+} \frac{1}{d^n} E \left( \sup_{B(x, \frac{R}{d})} |\sigma|^2 \right) \leq \frac{1}{2} \rho_R \delta_L.
\]
Likewise, we deduce from the mean value inequality that for every $s \in \mathbb{R}^+_+$, $j \in \{1, \cdots, n\}$ and $z \in B(x, \frac{R}{\sqrt{d}})$,
\[
\left| \frac{\partial \sigma}{\partial y_j} (z) \right|^2 \leq \frac{1}{Vol(B(\frac{R}{\sqrt{d}}))} \int_{B(0, \frac{R}{\sqrt{d}})} \left| \frac{\partial (\sigma \circ \psi^{-1}_x)}{\partial y_j} \right|^2 (y) dy,
\]
from which follows after summation over $j \in \{1, \cdots, n\}$ that
\[
E \left( \sup_{B(x, \frac{R}{\sqrt{d}})} |d\sigma|^2 \right) \leq \frac{1}{Vol(B(\frac{R}{\sqrt{d}}))} \int_{B(0, \frac{R}{\sqrt{d}})} E(\|d|\psi^{-1}_x|\sigma\|^2) dy.
\]
Let $z \in B(x, \frac{R}{\sqrt{d}})$ and for every $j \in \{1, \cdots, n\}$, $\sigma_j \in \mathbb{R}H^0(X, L^d)$ be the normed section orthogonal to the hyperplane of sections $\sigma$ such that $\frac{\partial \sigma}{\partial y_j} \cdot z = 0$. Still assuming that $dx = dV_h$, we know from Lemma 2.1 of [15], see also Lemma 2.2.3 of [6], that
\[
\|\frac{\partial \sigma_j}{\partial y_j}(z)\|_{h^d} \sim \pi \delta_L d^{n+1},
\]
so that again
\[
\left| \frac{\partial \sigma_j}{\partial y_j} (z) \right|^2 \leq \pi \delta_L e^{\pi(R+s)^2} d^{n+1} + o(d^{n+1}),
\]
where the $o(d^{n+1})$ can be chosen not to depend on $x \in \mathbb{R}X$. We deduce that
\[
E(|d\sigma|_z|^2) = \sum_{j=1}^{n} E\left(\left| \frac{\partial \sigma}{\partial y_j}(z) \right|^2 \right)
\]
\[
= \sum_{j=1}^{n} \frac{1}{\sqrt{\pi}} \int \frac{1}{2} \left| \frac{\partial \sigma_j}{\partial y_j}(z) \right|^2 e^{-a^2} da
\]
\[
\leq \frac{n}{2} \pi \delta_L e^{\pi(R+s)^2} d^{n+1} + o(d^{n+1}).
\]
Finally, $\limsup_{d \to \infty} \sup_{x \in \mathbb{R}^+} \frac{1}{d^n} E \left( \sup_{B(x, \frac{R}{\sqrt{d}})} |d\sigma|^2 \right) \leq \frac{3}{2} \pi \delta_L g_R(s)$. By choosing $s$ such that $g_R(s) = \rho_R$, see (5), we obtain the result in the case where $v = 1$ on $X$.

In general, the Bergman section at $x$ for the $L^2$-product (1) associated to the volume form $dx$ is equivalent to the Bergman section $\sigma_0$ at $x$ for $dV_h$ times $\sqrt{v(x)}$, because $\sigma_0$ has its $L^2$-norm concentrated on the ball $B(x, \log d/\sqrt{d})$. The same holds true for the $\sigma_j$’s, and the result follows by replacing $\delta_L$ with $v(x)\delta_L$. □
3.3 Probability of the local presence of closed affine hypersurfaces

Following the approach of F. Nazarov and M. Sodin (see [12] or also [10]), we deduce the following Proposition 3.3.1 from Propositions 3.1.4 and 3.2.1. It estimates from below the probability of presence, in a ball of radius inversely proportional to $\sqrt{d}$, of a given affine real algebraic hypersurface in the vanishing locus of sections of high tensor powers of an ample real line bundle.

Let $(X,c_X)$ be a smooth real projective manifold of positive dimension $n$ and $(L,h,c_L)$ be a real holomorphic Hermitian line bundle of positive curvature over $X$. Let $(U,P)$ be a regular pair given by Definition 2.2.2 and $\Sigma = P^{-1}(0) \subset U$. Then, for every $x \in \mathbb{R}X$, we set $B_d = B(x, \frac{R(U,P)}{\sqrt{d}})$ and denote by $\text{Prob}_{x,\Sigma}(L^d)$ the probability that $\sigma \in \mathbb{R}H^0(X,L^d)$ has the property that $\sigma^{-1}(0) \cap B_d$ contains a hypersurface $\Sigma'$ such that the pair $(B_d,\Sigma')$ be diffeomorphic to $(\mathbb{R}^n,\Sigma)$. That is,

$$\text{Prob}_{x,\Sigma}(L^d) = \mu_\mathbb{R}\left(\{\sigma \in \mathbb{R}H^0(X,L^d) \mid \sigma^{-1}(0) \cap B_d \supset \Sigma' \text{ and } (B_d,\Sigma') \sim (\mathbb{R}^n,\Sigma)\}\right).$$

We then set $\text{Prob}_\Sigma(L^d) = \inf_{x \in \mathbb{R}X} \text{Prob}_{x,\Sigma}(L^d)$.

**Proposition 3.3.1** Let $X$ be a smooth real projective manifold of positive dimension $n$ and $L$ be a real holomorphic Hermitian line bundle of positive curvature over $X$. Let $(U,P)$ be a regular pair given by Definition 2.2.2 and $\Sigma = P^{-1}(0) \subset U$. Then,

$$\liminf_{d \to \infty} \text{Prob}_\Sigma(L^d) \geq m_{\tau(U,P)},$$

see (3).

**Proof.** Let $x \in \mathbb{R}X$ and let us choose a $h$-trivialization of $(L,h)$ given by Definition 3.1.1. By Proposition 3.1.4, there exist, for every $d$ large enough, a compact $K_d$, an open set $U_d$ and a section $\sigma(U,P) \in \mathbb{R}H^0(X,L^d)$ such that

$$K_d \subset U_d \subset B_d \subset W_x,$$

and $(U_d,\sigma^{-1}(0) \cap U_d)$ be diffeomorphic to $(U,\Sigma)$. Moreover, for every $(\delta,\epsilon) \in \mathcal{T}(U,P)$,

$$\inf_{U_d \setminus K_d} |\sigma(U,P)| > \frac{\delta}{2} \sqrt{d^n}$$

and for every $z$ in $U_d$,

$$|\sigma(U,P)(z)| < \frac{\delta}{2} \sqrt{d^n} \Rightarrow |d_z\sigma(U,P)| > \frac{\epsilon}{2} \sqrt{d^{n+1}}.$$  \hspace{1cm} (22)

The moduli $|\sigma(U,P)|$ and $|d\sigma(U,P)|$ are computed here in the $h$-trivialization of $L^d$, see (12). Denote by $\sigma_P^\perp$ the orthogonal hyperplane to $\sigma(U,P)$ in $\mathbb{R}H^0(X,L^d)$ and by $s_P$ the orthogonal symmetry of $\mathbb{R}H^0(X,L^d)$ which fixes $\sigma_P^\perp$. Then, the average value of
sup_{B_d} |\theta|^2 on \sigma_{P}^1 satisfies

\[
E\left( \sup_{B_d} |\theta|^2 \right) = \int_{\sigma_{P}^1} \sup_{B_d} |\theta|^2 d\mu_R(\theta) = \int_{\mathcal{R}^0(X,L^d)} \sup_{B_d} \frac{|\sigma + s_P(\sigma)|^2}{2} d\mu_R(\sigma)
\]

\[
\leq \frac{1}{2} \int_{\mathcal{R}^0(X,L^d)} \sup_{B_d} |\sigma|^2 d\mu_R(\sigma) + \frac{1}{2} \int_{\mathcal{R}^0(X,L^d)} \sup_{B_d} |s_P(\sigma)|^2 d\mu_R(\sigma)
\]

\[
\leq E\left( \sup_{B_d} |\sigma|^2 \right) \leq \frac{1}{2} \delta_L \rho(\nu_P) v(x) d^n + o(d^n)
\]

from Proposition 3.2.1, where the \(o(d^n)\) does not depend on \(x \in \mathbb{R} X\). Likewise, from Proposition 3.2.1,

\[
E\left( \sup_{B_d} |d\theta|^2 \right) \leq \frac{1}{2} \delta_L \pi n \rho(\nu_P) v(x) d^{n+1} + o(d^{n+1}),
\]

where the \(o(d^{n+1})\) does not depend on \(x \in \mathbb{R} X\). From Markov’s inequality follows that for every \(M > 0\),

\[
\mu_R \left( \{ \theta \in \sigma_{P}^1 | \sup_{B_d} |\theta|^2 \geq M^2 v(x) \frac{\delta_L^2}{4 M^2} d^n \} \right) \leq \frac{2 \|P\|_{L^2(\nu_P)}^2 \rho(\nu_P)}{M^2 \delta_L^2} + o(1)
\]

and

\[
\mu_R \left( \{ \theta \in \sigma_{P}^1 | \sup_{B_d} |d\theta|^2 \geq M^2 v(x) \frac{\epsilon^2 \delta_L^2}{4 M^2} d^{n+1} \} \right) \leq \frac{2 \pi n \|P\|_{L^2(\nu_P)}^2 \rho(\nu_P)}{M^2 \epsilon^2} + o(1),
\]

where \(o(1)\) does not depend on \(x \in \mathbb{R} X\). As a consequence, setting

\[
\mathcal{E}_{\sigma_{P}^1} = \{ \theta \in \sigma_{P}^1 | \sup_{B_d} |\theta|^2 < M^2 v(x) \frac{\delta_L^2}{4 M^2} d^n \text{ and sup }_{B_d} |d\theta|^2 < M^2 v(x) \frac{\epsilon^2 \delta_L^2}{4 M^2} d^{n+1} \}
\]

we have

\[
\mu_R(\mathcal{E}_{\sigma_{P}^1}) \geq 1 - 2 \frac{\|P\|_{L^2(\nu_P)}^2 \rho(\nu_P)}{M^2} \left( \frac{1}{\delta_L^2} + \frac{\pi n}{\epsilon^2} \right) - o(1),
\]

where the \(o(1)\) does not depend on \(x\). Choosing \((\delta, \epsilon)\) which minimizes the function \((\delta, \epsilon) \mapsto \left( \frac{1}{\delta^2} + \frac{\pi n}{\epsilon^2} \right)\), we deduce from (7) that \(\mu_R(\mathcal{E}_{\sigma_{P}^1}) \geq 1 - \frac{7(\nu_P)}{M^2} - o(1)\). Now, setting

\[
\mathcal{F}_{M, \nu_P} = \left\{ a \frac{\sigma_U(\nu_P)}{\|\sigma_U(\nu_P)\|_{L^2}} + \theta \in \mathcal{R}^0(X,L^d) | a > M \text{ and } \theta \in \mathcal{E}_{\sigma_{P}^1} \right\},
\]

where

\[
\|\sigma_U(\nu_P)\|_{L^2} \sim \frac{\sqrt{v(x) \delta_L}}{\|P\|_{L^2}} \quad (23)
\]

16
by the first part of Proposition 3.1.4 and the fact that the mass of \( \sigma(U, P) \) concentrates on small balls \( B(x, \log d/\sqrt{d}) \). Take \( \sigma \in \mathcal{F}_{\mathbb{R}(U, P)} \). From the estimates (21), (22), (23) and the definition of \( \mathcal{E}_{\sigma, \bar{\rho}} \), for large enough \( d \), 0 is a regular value of \( \sigma \) and from Lemma 3.1.6, \( \sigma^{-1}(0) \cap U_d \) is isotopic to \( \sigma^{-1}(0) \cap U_d \), so that the pair \((B_d, \sigma^{-1}(0) \cap U_d)\) is diffeomorphic to \((B(0, R(U, P)), \Sigma)\). The result follows from the fact that

\[
\text{Prob}_{x, \Sigma}(L^d) \geq \mu_{\mathbb{R}}(\mathcal{F}_{\mathbb{R}(U, P)}) \geq \left( \frac{1}{\sqrt{\pi}} \int_{M}^{+\infty} e^{-t^2} dt \right) \left( 1 - \frac{\tau(U, P)}{M^2} - o(1) \right) = f_{\tau(U, P)}(M) - o(1),
\]

see §2.1. We choose \( M \in [\sqrt{\tau(U, P)}, +\infty] \) which maximizes \( f_{\tau(U, P)} \), see (3), and take the limit. □

**Proof of Theorem 1.0.2.** Let \((U, P) \in \mathcal{I}_\Sigma \), see §2.2. For every \( d > 0 \), let \( \Lambda_d \) be a maximal subset of \( \mathbb{R}X \) with the property that two distinct points of \( \Lambda_d \) are at distance greater than \( \frac{2R(U, P)}{\sqrt{d}} \). The balls centered at points of \( \Lambda_d \) and of radius \( \frac{R(U, P)}{\sqrt{d}} \) are disjoints, whereas the ones of radius \( \frac{2R(U, P)}{\sqrt{d}} \) cover \( \mathbb{R}X \). For every \( x \in \Lambda_d \) and every \( \sigma \in \mathbb{R}H^0(X, L^d) \setminus \mathbb{R}\Delta_d \), we set \( N_\Sigma(x, \sigma) = 1 \) if the ball \( B_d \) contains a hypersurface \( \Sigma' \) such that \( \Sigma' \subset \sigma^{-1}(0) \) and \((B_d, \Sigma')\) is diffeomorphic to \((\mathbb{R}^n, \Sigma)\), whereas \( N_\Sigma(x, \sigma) = 0 \) otherwise. Recall that \( N_\Sigma(\sigma) \) denotes the maximal number of disjoint open subsets of \( \mathbb{R}X \) having the property that each such open subset \( U' \) contains a hypersurface \( \Sigma' \) such that \( \Sigma' \subset \mathbb{R}C_\sigma \) and \((U', \Sigma')\) be diffeomorphic to \((\mathbb{R}^n, \Sigma)\). Thus,

\[
E(N_\Sigma) \geq \int_{\mathbb{R}H^0(X, L^d) \setminus \mathbb{R}\Delta_d} \left( \sum_{x \in \Lambda_d} N_\Sigma(x, \sigma) \right) d\mu_{\mathbb{R}}(\sigma)
= \sum_{x \in \Lambda_d} \text{Prob}_{x, \Sigma}(L^d)
\geq |\Lambda_d| \text{Prob}_{\Sigma}(L^d)
\]

by Proposition 3.3.1. We deduce from the inclusion \( \mathbb{R}X \subset \bigcup_{x \in \Lambda_d} B(x, \frac{2R(U, P)}{\sqrt{d}}) \) that

\[
\text{Vol}_h(\mathbb{R}X) \leq \sum_{x \in \Lambda_d} \text{Vol}(B(x, \frac{2R(U, P)}{\sqrt{d}}))
\leq 2^n |\Lambda_d| \text{Vol}(B_d) + o\left( \frac{|\Lambda_d|}{\sqrt{d}} \right).
\]

From Proposition 3.3.1 follows then that

\[
\liminf_{d \to \infty} \frac{1}{\sqrt{d}} E(N_\Sigma) \geq \frac{m_{\tau(U, P)} \text{Vol}_h(\mathbb{R}X)}{2^n \text{Vol}(B_d)}.
\]

This lower bound holds for every pair \((U, P) \in \mathcal{I}_\Sigma \) and we get the result by taking the supremum, see (8). □
Proof of Corollary 1.0.3. For every $d > 0$,

$$E(b_i) = \int_{RH^0(X,L^d)\setminus R\Delta_d} b_i(RC_\sigma, \mathbb{R}) d\mu_\mathbb{R}(\sigma)$$

$$\geq \int_{RH^0(X,L^d)\setminus R\Delta_d} \left( \sum_{\Sigma \in \mathcal{H}_n} N_\Sigma(\sigma) b_i(\Sigma) \right) d\mu_\mathbb{R}(\sigma)$$

$$\geq \sum_{\Sigma \in \mathcal{H}_n} b_i(\Sigma) E(N_\Sigma).$$

Hence, the first lower bound follows from Theorem 1.0.2, while the second one follows along the same lines. The last part of Corollary 1.0.3 is then a consequence of Proposition 2.3.3. □
