**The impact of trade credit on customer switching behaviour:
evidence from the Tanzanian rice market**

Abstract

We use primary survey data to analyse the relationship between trade credit and customer switching in the context of trade transactions between wholesalers and retailers in the Tanzanian rice market. Results reveal a negative relation of trade credit and customer switching, that is, trade credit acts as a switching barrier; retailers are reluctant to move to another supplier if they depend on trade credit as a source of external finance. This interpretation fits with the underdeveloped financial markets in Tanzania, in which access to external finance is poor among rice retailers.

Key words: customer switching; trade credit; rice market; Africa; Tanzania

JEL classification: L12, L14

Introduction

Customer switching is a critical issue for suppliers of goods and services as it may adversely affect the market share and profitability of the firm (Keaveney, 1995). If customers can easily switch to new suppliers (switching costs are low) suppliers face more elastic demand, which may lead to lower mark-ups over their marginal costs, ultimately reducing the supplier's overall profitability. Recognising the potential adverse effects of customer switching, firms develop strategies to prevent it, often by increasing customer loyalty (Rust and Zahorik, 1993; Sheth and Parvatiyar, 1995; Liu, 2006). In this context, trade credit might provide a viable instrument for both preventing customer switching (McMillan and Woodruff, 1999; Cheng and Pike, 2003; Fisman and Raturi, 2004; Van Horen, 2005) and creating customer loyalty (Cheng and Pike, 2003; Bigsten and Soderbom, 2006). Yet little empirical evidence supports this claim, because studies dealing with customer switching generally overlook the role of trade credit, mostly due to a lack of sufficient data. To extend the literature, we examine explicitly whether offering trade credit can establish a switching barrier and reduce customer switching behaviour in the context of the Tanzanian rice market.

We consider this setting an interesting case for several reasons. Tanzania is a poor country with an underdeveloped financial system, so trade credit is likely to be an important source of financing for many businesses, including traders in the rice market. The results of a 2007 study reveal that approximately 70 per cent of transactions between rice wholesalers and retailers rely on credit terms. Moreover, most traders in the rice market lack access to sources of outside finance, such as bank loans (Kihanga, 2010).

We use survey data that provide detailed cross-sectional information about 276 rice trading relationships between wholesalers and retailers in Tanzania. With this survey, we can measure different types of switching barriers that rice retailers confront, including the provision of trade credit. To the best of our knowledge, this study is the first to use detailed transaction-based data to assess the importance of trade credit as a device to curb customer switching.

In the next section, we review literature on customer switching, including a discussion of the use of trade credit to prevent such switching. We then outline the data, including our variable identification and definition. After a description of the econometric methodology and framework, we present the descriptive statistics and estimation results. Finally, we conclude and offer suggestions for further research.

I. Customer switching: A brief review

Customer switching refers to the migration of customers from one supplier to another, such that the customer buys goods from a different supplier (Ranganathan et al., 2006). Because customer switching adversely affects the profitability of suppliers, they tend to implement deliberate strategies, such as advertising and promotion and pursuing long-term customer relationships, to reduce the probability of customer switching. These tactics in general aim to erect switching barriers. For our analysis of customer switching behaviour in the Tanzanian rice market, we focus on deliberate strategies to create such barriers, based on long-term relationships, including the provision of trade credit¹.

Trade credit as a switching barrier

Several studies have investigated the provision of trade credit by suppliers as a device to prevent customer switching (Nadiri, 1969; McMillan and Woodruff, 1999; Fisman and

1
2
3 Raturi, 2004; Van Horen, 2005), usually from the perspective of resource dependency
4 theory, which states that firms rarely are completely self-sufficient with respect to critical
5 resources. They depend on other firms to provide these resources (Pfeffer and Nowak,
6 1976; Pfeffer and Salancik, 1978; Pfeffer, 1982; Heide, 1994; Paulraj and Chen, 2007).
7
8
9

10
11
12 For example, many firms are not self-sufficient when it comes to the critical resource
13 of finance, such that they are financially constrained. Internal financial sources often are
14 not sufficient for making short-term payments or long-term investments, nor can firms
15 always attract external finance, such as from banks or capital markets. An alternative
16 source of external finance therefore comes from the trade credit offered by suppliers.
17 Trade credit may relax financial constraints of customers and cover at least their short-
18 term financing needs (Petersen and Rajan 1994; Nielsen, 2002).
19
20
21
22
23
24
25
26
27
28

29 Suppliers may not provide trade credit to all clients though. Some studies even argue
30 that trade credit goes only to those customers with which suppliers have developed long-
31 term relationships through repeat purchases (Biggs and Shah, 2006; Giannetti et al.,
32 2008). Suppliers appear to prefer to establish a thorough understanding of the borrower's
33 creditworthiness and trustfulness, to reduce their potential risk of default.
34
35
36
37
38
39

40
41 If customers depend on trade credit as a source of short-term finance, but trade credit
42 gets supplied after the establishment of a long-term relationship, finance-dependent
43 customers that receive trade credit are likely to persist in their existing trade relationships
44 with suppliers, to ensure ongoing access to short-term finance (Neale and Schmidt, 1991).
45 This dependence on trade credit thus works as a switching barrier, because switching to a
46 new supplier may be costly: The customer could lose access to short-term finance and
47 would have to expend time to establish a new relationship with a new supplier to gain
48

58
59
60

access to its trade credit. In other words, the potential lack of trade credit that results from switching to a new supplier acts as a tax on customers that ties them to their current supplier.

Interpersonal relationships

Switching behaviour can also be limited by interpersonal relationships between suppliers and customers, reflecting the strength of personal ties or social bonds (Berry and Parasuraman, 1991) developed through regular contacts (Wilson, 1995). They can be described along several dimensions, such as familiarity, care, friendship, and trust (Gremler, 1995). Stronger ties imply a stronger interpersonal relationship.

The interpersonal relationships that develop between a supplier and customers can create a psychological effect on the customer's decision to switch and become a customer of a new supplier (Klemperer, 1995). Burnham et al. (2003) call this effect relational switching costs, which involve psychological or emotional discomfort associated with ending the close relationship with the supplier. This perceived discomfort creates a barrier to switching (Patterson et al., 2001). Money (2004) further shows that the perceived social consequences of switching can have negative impacts on the likelihood of switching. Finally, the strength of the interpersonal relationship often depends on the length of that relationship. Customers may prefer to continue a relationship with suppliers with which they have long trading relationships, because they have extensive experience with this supplier (Riordan and Griffet, 1995; Wathne et al., 2001; Money, 2004). This experience also can develop into a switching barrier. Empirical evidence shows that the length of a relationship between trading parties indeed reduces switching behaviour (Chakravarty et al., 2004; Money, 2004; Ranganathan et al., 2006). In the banking

literature the length of the relationship between a bank and its clients is often used as an indicator of relational ties. Several studies have shown that these ties reduce the probability of switching (Petersen and Rajan, 1994; Berger and Udell, 1995; Chakravarty et al., 2004).

Availability and attractiveness of alternatives

The number of alternative suppliers in a market and the attractiveness of the goods and services they offer also may influence the decision to remain with or change suppliers (Colgate and Lang, 2001). When alternatives are available, the customer has a wider choice spectrum and greater possibilities for switching. In contrast, if there are no or few alternatives available, switching may be difficult, because the customer lacks viable options (Jones et al., 2000; Kiser, 2002; Roos et al., 2004). Thus, a lack of alternatives serves as a switching barrier.

A customer will consider switching to an alternative supplier if this supplier offers a product of higher quality (Kiser 2002; Patterson and Smith, 2003) or lower price (Wathne et al., 2001; Polo and Sese, 2009), as well as if the customer has a bad experience with the current supplier, provided that alternative suppliers offer better quality (Jones and Sasser, 1995). However, switching is unlikely if the available alternatives are not superior to the current supplier (Anderson and Narus, 1990; Ping, 1993; Kranton, 1996; Patterson and Smith, 2003; Tahtinen and Vaaland, 2006).

Several empirical studies confirm that alternatives in the market increase the probability of switching. Tahtinen and Vaaland (2006) show that the probability of switching declines when customers perceive a lack of alternatives, and Chen and Hitt (2002) offer evidence showing that customers with few suppliers are less likely to switch.

Kiser (2002) finds that firms that maintain relationships with many banks (that is suppliers) often switch service providers.

Search costs

Several studies focus on the time customers need to devote to finding a new supplier that can provide the same or better goods and services than the current supplier—that is, they focus on the search costs customers must pay to switch suppliers (Dwyer et al., 1987; Klemperer, 1995; Padilla, 1995; Jones et al., 2000; Tahtinen and Vaaland, 2006). A customer needs to invest sufficient time in the relationship to obtain certain privileges (price discounts, trade credit), because many suppliers provide such privileges only to loyal customers (Biggs and Shah, 2006; Giannetti et al., 2008). The time needed to establish a trade relationship thus may reduce the probability of customer switching.

II. Data

The data for this study were collected through structured questionnaires distributed to rice traders in Tanzania. The questionnaire contains detailed items about specific rice trade transactions, as well as the characteristics of the parties involved in these transactions. We have information about matching pairs of participants in trade relationships; for each wholesaler included there is information about the most recent transactions with two customers (retailers) and their individual characteristics.

The sampling strategy entailed the following approach: We visited rice trade markets in different cities and randomly chose retailers to interview. The retailers provided personal information and details related to the last rice transaction in which they had been involved. After the interview, we asked the retailer to provide the name and contact

address of the wholesaler from which he or she bought rice supplies most recently, as well as the name and contact address of another retailer that bought from the same wholesaler. We contacted the identified wholesaler and retailer and visited them to obtain information, using the same survey instrument². With this snowball sampling approach (Goodman, 1961; Heckathorn, 1997)³, we finally managed to interview 141 wholesalers and 276 retailers. For 135 wholesalers we have detailed information about transactions with two customers; for the other six we have information about transactions with only one customer.

Before the final survey, we carried out a pilot study (May–August 2007) amongst a small sample of wholesalers and retailers. In this study we used a draft version of a structured questionnaire, which contained questions related to several characteristics of rice trade transactions, switching behaviour and the existence of switching barriers. In particular the questions pertained to the number of suppliers with which the retailer traded rice, whether the retailer had stopped buying from any specific supplier in the past two years, whether the retailer started purchasing from (that is, switched to) another supplier(s), whether the retailer was considering switching suppliers in the near future, the length of the trading relationship between the retailer and a specific supplier, the retailer's knowledge about other suppliers, whether the retailer can obtain trade credit from a new supplier in an initial transaction and whether the retailer anticipated feeling discomfort if he or she were to switch suppliers.

The final questionnaire, conducted during January–August 2008, included rice traders from the following cities: Dar es Salaam, Dodoma, Morogoro, Iringa and Mbeya. Dar es Salaam is the largest urban market centre for agricultural products. Dodoma is

located in a region with a rice deficit. Morogoro, Iringa and Mbeya are all large regional rice surplus centres.

Defining variables

We begin with a measure of customer switching, which is our dependent variable. We measure switching with a dummy variable that is equal to 1 if a retailer stopped buying on a regular basis⁴ from the supplier who participated in the most recent transaction during the previous two years⁵. If the retailer has been buying from the same supplier over the entire two-year period, the dummy variable equals 0. Several studies use similar measures to denote switching behaviour (Chen and Hitt, 2002; Ranganathan et al., 2006; Tseng and Liu, 2007).

Our variable of interest is trade credit received by the retailer. Trade credit is usually measured in terms of the amount of delayed payments. Based upon our discussion in section 2, we argue that retailers, who are more dependent on trade credit received from the supplier as a source of finance, are more likely to face difficulties to switch. We measure dependence on trade credit as the fraction of the total value of traded rice for which payment is delayed. This measure of trade credit is standard in literature. We expect that the retailer's willingness to switch decreases as the dependence on trade credit from the supplier increases. In other words we expect a negative relationship between the probability of switching and the amount of trade credit a retailer receives⁶.

Several control variables may explain switching behaviour, as we noted previously. First we include two variables that relate to the interpersonal relationships between the retailer and the supplier, reflecting perceived psychological discomfort associated with switching and the length of the trading relationship. Psychological discomfort is a dummy

variable, equal to 1 if a retailer indicates he/she feels discomfort with the idea of replacing the supplier, and 0 otherwise. We expect a negative relationship between switching behaviour and this perceived discomfort. To take the length of the trading relationship into account, we measure the number of years a retailer has been a customer of the supplier, as used in previous studies (Chakravarty et al., 2004; Carrasco and DeMello, 2006). We expect a negative relationship between switching and the length of the relationship.

Second we include measures of the availability and attractiveness of alternative suppliers compared with the current supplier. The measure of the availability of alternative suppliers reflects the number of suppliers from which a retailer purchases rice. Because switching is easier if alternative suppliers are available, there should be a positive relationship between this variable and switching behaviour. The attractiveness of alternatives is measured in terms of whether other suppliers offer rice at a cheaper price than the current supplier. This dummy variable reveals whether the retailer notes a difference in prices for the same type of rice offered by other suppliers. If a retailer indicates no price differences, we consider it evidence of a lack of better alternatives, so the dummy variable takes a value of 1 (and 0 otherwise). A retailer seemingly has less incentive to switch if competitors do not offer rice at a cheaper price; thus we expect a negative relationship between switching and the dummy variable that measures the lack of better alternative suppliers

Third we consider the perceived time it takes to find a new supplier. As discussed in section 2, the existence of information asymmetry requires a customer to build a close relationship with and communicate its creditworthiness to the supplier to earn privileges

(including trade credit). The time needed to build such a close relationship with a new supplier represents a switching cost. We measure the perceived time to build a relationship with a dummy variable, taking the value of 1 if a retailer states that he or she will not get trade credit in an initial transaction with a new supplier and 0 otherwise. We expect a negative relationship between the probability of switching and this dummy variable⁷.

III. Methodology

The empirical question that this paper aims to answer is whether trade credit reduces the switching behaviour of customers. To investigate the effect of trade credit on customer switching, we model switching behaviour as a function of trade credit, including control variables that measure interpersonal relationships, the availability of alternatives and search costs. We use a probit regression model because the underlying dependent variable is a binary dummy variable. The choice for the probit model implies that we assume a standard normal distribution.

The relationship between trade credit and customer switching may suffer from a selection problem. A negative effect of trade credit on customer switching may reflect correlations between trade credit and unobserved variables that affect customer characteristics. Moreover, the causality may be reversed: if a customer does not switch, it may indicate trust in the relationship between the supplier and the customer, facilitating access to trade credit.

We address these concerns in two ways. First, we examine whether our main result disappears if we include unobserved variables that explain customer switching and at the

1
2
3 same time are correlated with trade credit. In line with Altonji et al. (2005), Bellows and
4
5 Miguel (2009) and Voors et al. (2011), we investigate the extent to which the coefficient
6
7 of the trade credit variable changes when we include control variables. If adding the
8
9 controls attenuates the trade credit coefficient, our results likely suffer from an omitted
10
11 variable bias. More specifically, by comparing the coefficient of the trade credit variable
12
13 in a model without controls with that in a model with a full set of controls, we can
14
15 calculate the extent to which adding controls attenuates the magnitude of the estimated
16
17 coefficient. By assuming that the possible bias due to selection on unobservables can be
18
19 proxied by the bias due to selection on observables, we can estimate how large the
20
21 selection on unobservables would need to be to explain away the entire effect of trade
22
23 credit on switching.
24
25
26
27
28

29 Second we address possible endogeneity by applying an instrumental variable (IV)
30
31 approach. To estimate the probit model with instrumental variables (IV probit) for trade
32
33 credit, we use three variables: the log of the volume of purchase, the log of the number of
34
35 years the retailer has been in business and the log of the size of the business activities of
36
37 the retailer, measured by annual revenues. Transaction cost theory postulates that a larger
38
39 purchase volume reduces the costs of storage and invoicing for the supplier (Petersen and
40
41 Rajan, 1997). Chung and Liao (2006) confirm that these cost reductions encourage
42
43 suppliers to provide trade credit. Hermes et al. (2010) show that in the Tanzanian rice
44
45 market transaction costs have an important influence on the decision to provide trade
46
47 credit, because the volume of purchase relates positively to trade credit.
48
49
50
51
52

53 Using financing theory, several authors (Petersen and Rajan, 1997; Summers and
54
55 Wilson, 2002; Giannetti et al., 2008) identify a negative relationship among trade credit,
56
57
58
59
60

1
2
3 firm age and firm size. That is, older and larger firms have easier access to alternative
4 sources of external finance, such as bank loans, which attenuates their need for trade
5 credit. When firms persist longer in business, they establish their reputation for survival,
6 which also signals their ability to repay loans. Larger firms have better access to bank
7 loans, because lending and monitoring costs experience economies of scale, such that it is
8 more profitable for banks to make loans to larger firms. In the Tanzanian rice market,
9 retailer characteristics—including the length of time in business and the size of business
10 activities—correlate negatively with access to trade credit, in support of previous studies
11 that test the financing theory of trade credit (Hermes et al., 2010). These retailer
12 characteristics should help explain access to trade credit, because in Tanzania, the
13 banking system is relatively underdeveloped, and its activities are seriously hampered by
14 asymmetric information problems. Therefore only experienced large retailers have access
15 to bank loans; others have to rely on trade credit.

25
26
27
28
29
30
31
32
33

34 A priori, we do not expect that the three IVs have direct relationships with switching
35 behaviour (the correlations between the instruments and customer switching appear low).
36 Although the validity of the instruments is tested, the 2SLS regressions have poor small
37 sample properties so the IV estimates are treated as additional robustness checks of the
38 probit estimates. Given the limitations of the tests used to deal with potential selection
39 problem all results should be interpreted with reservation. The IV probit model provides a
40 forecast value for trade credit used in the re-estimation of the model of switching
41 behaviour. The IV Probit command in Stata is used so the two equations are estimated
42 simultaneously (with automatic adjustment of standard errors).

IV. The Tanzanian rice market: Descriptive statistics

During the 1970s and 1980s the Tanzanian rice market was strongly regulated by the Marketing Board for Cereals and the National Milling Corporation. The government overtly discouraged private grain traders. For example, the quantity that could be purchased at a time from farmers in other regions was restricted. Road blocks were used to enforce this rule. Yet, the disappointing economic performance of the Tanzanian economy and the interventionist government policies led the International Monetary Fund to insist on marketing reforms. During the late 1980s food crop markets were deregulated and controls on domestic trade of food were abolished. Since the 1990s Tanzanian food policy has been characterized by low levels of government intervention in agricultural markets.

As a result of the deregulation of the agricultural markets a large number of rice retailers and wholesalers became active in the regional and urban market places.⁸ Due to the fact that there are many rice suppliers active in the market, wholesalers aim at establishing a close relationship with retailers, traditionally known as *uteja wa kudumu* (in Swahili). As was made clear by most wholesalers during the interviews we had with them as part of our pilot study (May–August 2007), a large part of the transactions with their regular retailers is credit-based (referred to as a *mali kauli* transaction). The retailers we interviewed confirmed that building close relationships with suppliers improves access to trade credit and better credit terms. Finally, both wholesalers and retailers stated that close trading relationships enhance the sharing of information between trading partners.

60

The above observations regarding the importance of trade credit and close relationships between trading partners in the Tanzanian rice market are corroborated by the data from our questionnaire. Table 1 presents descriptive statistics of the variables in our model of the probability of customer switching. The majority of retailers (73 per cent) have not switched in the past two years and nearly as many (67 per cent) receive trade credit from their suppliers. Trade credit thus emerges as an important financial source; losing access to trade credit may be a potential barrier to switching.

<Insert table 1 here>

Establishing a relationship with a supplier to obtain trade credit can take time, in that 53 per cent of the retailers in the sample state that they would not get trade credit in the first transaction with a new supplier if they switched. Thus switching may be costly for a retailer. Only 25 per cent of the surveyed retailers would experience discomfort from switching to another supplier, suggesting that perceived discomfort does not appear to be a barrier for retailers. Moreover, retailers have developed relatively long trading relations with their wholesalers: The average length of trade relationships is more than four years, which implies that retailers do not switch easily. Most retailers perceive the attractiveness of alternatives as rather low. They tend to purchase rice regularly from between one and two suppliers, and a little more than half of the retailers indicate there are no price differences for the same type of rice offered by different suppliers in the market. Thus retailers appear to have low incentives to switch.

V. Estimation results

Table 2 presents the results of the probit regressions that indicate the probability that a customer will switch to another supplier. We first present a base model that includes only

trade credit. In alternative specifications, we then add one or more control variables to the base model. Model 5 provides the results for the full model including all control variables⁹. In all these models, trade credit has a significant negative effect on the probability of switching. This result likely reflects the dependence of retailers on trade credit as a source of external finance, which should not be surprising considering the underdeveloped financial markets in Tanzania and minimal access to external financing among rice retailers. Dealing with a supplier who provides trade credit thus offers an incentive to continue the trading relationship with this supplier.

<Insert table 2 here>

We also find support for other switching barriers. First the time it takes to establish a relationship with a new supplier before trade credit is extended acts as a barrier. Second we find that the lack of alternative suppliers that offer better prices discourages retailers from switching as changing suppliers would not result in any economic gain. The other variables used to measure switching barriers are not significant.

Testing for potential selection problems

To test for potential selection problems, we first examined whether the main result disappears if unobserved variables that explain customer switching and correlate with trade credit are included. As the results in Table 2 show, adding five observed control variables reduces the coefficient from -2.49 to -1.88, that is, attenuates the coefficient by 0.62. In line with Bellows and Miguel (2009) we assume that the ratio between the coefficient with controls (coef_c) and the difference between the coefficient without and with controls ($\text{coef}_c - \text{coef}_{nc}$) offers a proxy for how strong the covariance between the unobserved variables and trade credit must be, relative to the covariance between the

observed variables and trade credit, to explain away the entire effect. In our case, the targeting on unobserved variables should be more than three times greater¹⁰ than the amount of targeting on observed variables if we were to explain away the entire effect of trade credit. Altonji et al. (2005) argue that the ratio of selection on unobservables relative to observables should be less than 1. Because our ratio is 3, this suggests that at least part of the observed effect of trade credit on customer switching is real.

We re-performed the empirical analysis that produced the results in Table 2 using an IV approach to address potential endogeneity problems. The results of the IV Probit regression results in Table 3 still suggest that trade credit has a significant negative effect on the probability of switching.

<Insert table 3 here>

The reliability of these results clearly depends on the validity of the instruments. In the Appendix (Table A2) we provide the first-stage regression results, with trade credit as the dependent variable. The R-squared value of the first-stage regression is rather high, and two of the three instruments we used (volume of purchase and size of the retailer's business activities) are strongly significant. Our regression thus does not suffer from weak instruments. Moreover, we perform a Wald test of exogeneity to test the null hypothesis that trade credit is exogenous. The results (see Table 2) show that the *p*-value of the Wald test is very low; therefore, trade credit is endogenous, and we have support for the relevance of using instruments. Moreover, the Amemiya-Lee-Newy minimum chi square test (Table 3) to determine if the instruments are correlated with the residual from the second-stage regression is insignificant, suggesting that the instruments are valid. We

do realize, however, that, even if the statistical tests seem to support the validity of our instruments, it does not necessarily mean that we have selected the right instruments.

Accepting the choices regarding instruments, the results in Table 3 confirm our findings from Table 2 with respect to trade credit as an important switching barrier. Even after acknowledging that trade credit is an endogenous variable, our analysis shows that the probability of retailers switching suppliers correlates negatively with the amount of trade credit they receive. Thus for retailers in the rice market in Tanzania, access to trade credit is an important impediment to switching suppliers.

The results for the other switching barriers in our model also remain similar; that is, the time it takes to establish a relationship with a new supplier before trade credit is obtained and the lack of alternative suppliers act as other barriers.

VI. Conclusions and further research

We have analysed the relationship between trade credit and customer switching in the context of trade transactions between wholesalers and retailers in the Tanzanian rice market. Our hypothesis states that trade credit acts as a barrier that reduces the probability of customer switching. Our study is one of the first to empirically verify this claim.

Using survey data from 276 trade relations between rice wholesalers and retailers, we find evidence in support of the view that trade credit reduces the probability of customer switching. We interpret this result to indicate that trade credit acts as a switching barrier. Retailers are reluctant to move to another supplier if they depend on trade credit as a source of external finance. They could lose access to short-term finance and would have to expend time to establish a new relationship with a new supplier to gain access to trade credit. The potential lack of trade credit that results from switching to a new supplier acts

as a tax on customers that ties them to their current supplier. The above interpretation corroborates with the status of financial markets in Tanzania, which remain underdeveloped, such that access to external finance often is minimal for rice retailers.

The relationship between trade credit and customer switching may be subject to a potential selection problem though, which prompted us to perform two tests to address this concern. We examined if our main result disappeared if we included unobserved variables that both explain customer switching and correlate with trade credit (Altonji et al., 2005), and we re-estimated the relationship between trade credit and customer switching with a probit model with instrumental variables. Both tests support our main finding that trade credit acts as a barrier to switching. However, we acknowledge the limitations of these two tests and therefore recommend that our results be interpreted with some caution.

Notwithstanding these limitations, and accepting the validity of the outcomes, our study offers several policy implications, especially for local banks in Tanzania. The finding that retailers often receive trade credit from their suppliers implies that they are credit constrained and could be potential targets for extended lending activities. Furthermore, the receipt of trade credit can be a signal of quality, because suppliers likely provide trade credit only to those retailers that represent a low risk of default on that credit. Local Tanzanian banks could use access to trade credit as a screening device for their loan decisions as well. This role of access to trade credit, that is, as a signal of a firm's credibility that can facilitate access to bank loans, also has been confirmed by Alphonse et al. (2006).

The results of our empirical analysis are also relevant for participants in food markets in other Sub-Saharan African countries. In many of these countries food trade is an important business opportunity; yet many traders lack access to formal financial institutions. Trade credit received from their suppliers facilitates their business activities. The price they pay is a reduced freedom to switch.

One of the remaining key questions is whether trade credit improves the functioning of food markets or whether it establishes a barrier to competitive processes. Our study does not directly assess this issue. Consequently, we are unable to conclude whether or not trade credit is an efficient instrument to provide retailers access to finance. Put differently, our research does not allow us to answer the question whether trade credit in the rice market is cheaper than alternative sources of external finance as a result of lower transaction costs (reduced information asymmetry), or whether trade credit allows wholesalers to realize profits above normal rates of return as a result of lock-in (reduced threat of switching). Existing literature provides theory for both outcomes. Further research is needed to elaborate on this important issue.

On-going research should further focus on developing a setting to test more accurately for potential selection problems. Researchers also might focus on further tests of the role of trade credit in different markets and industries, both within and outside Tanzania. Finally, creating a panel data set that reveals the use of trade credit and switching behaviour would support investigations of any changes in the relationship over time, such as due to changes in the development of financial markets.

Prob > F	0.000
R-Squared	0.48
Number of observations	272

Notes: Standard errors are in parentheses. Dependent variable = trade credit.

¹ Advertising and promotions generally do not play any role in this market.

² The selected retailers and wholesalers were all active in the marketplace. One may argue that they do not necessarily constitute a representative sample of traders. Regrettably, most traders active in rice markets are not formally registered. Their informal status complicates any measure of representative sampling. However, the marketplaces we visited are centers of food distribution in Tanzania, which provides some confidence that a random sampling of rice traders active in these marketplaces provides a reasonable guarantee for obtaining a representative sample.

³ In snowball sampling, existing respondents recruit new respondents they know to create a sufficiently large final sample. This technique is common in sociological research that studies a population that is difficult to approach, such as drug users or alcoholics. In our case, the technique enabled us to solve the problem of finding traders who buy from the same wholesaler.

⁴ Retailers deal with an average of 1.7 suppliers on a regular basis (see Table 1). Seasonality in supply and variation in the quality of rice forces retailers to work with more than one supplier. Thus switching implies not that retailers buy from different suppliers but rather that they cease to buy on a regular basis from a specific supplier.

⁵ The two-year period reflects the study context. Business relationships in this market tend to be quite long. The retailers indicated that on average the business relationship with their focal supplier has lasted for more than four years (Table 1). The minimum we observed was one year. In this context retailers were asked to indicate whether they stopped buying from this supplier for some period of time during the previous two years. If the business relationship was younger than one year and the retailer had been in business for more than a year, switching had taken place.

⁶ It could be argued that trade credit obtained recently does not influence switching in the last two years but switching in the future. Ideally our data on switching would concern the future. However, data collection on switching in the future is quite difficult to organize as it needs a second interview, later in time. Alternatively, the transaction considered in the survey could be a transaction that took place in the past. The disadvantage of such a format is the risk of imprecise answers if traders incorrectly recall their past transactions. We suggest that trade credit today is a good proxy for trade credit use in the past because it is based on past experience in the business relationship. Trade credit conditions are likely to evolve gradually as trust builds slowly.

⁷ In the Appendix, Table A1 provides an overview of the variables used to measure switching behavior (dependent variable) and switching barriers, including trade credit (independent variables). The table also reveals the expected signs for the independent variables in the empirical analysis.

⁸ No official data on the number of traders are available due to the fact that rice traders generally are not registered

⁹ We do not present the results for all possible combinations of control variables, because the variables that proxy for the length of the trade relationship, the number of alternative suppliers and perceived discomfort are not significant. These variables only appear in the full model, in which we include all controls.

¹⁰ Hence, $\text{coef}_c / (\text{coef}_{nc} - \text{coef}_c) = 1.88/0.62 = 3$.
