Abstract

In order to explain the fact that the pressure in the Friedmann equations is negative, only the hypothetical presence of dark energy is used in present theories. But, the dimensions of the pressure p are f/r^2 and thus p can not account for the acceleration of the expansion of the universe. Indeed, the hypersurface of our universe is threedimensional and curved, so a force has an effect on the universe if it is applied on the universe's boundaries. As these boundaries (hypersurface) correspond to the threedimensional universe itself at time t , there must exist a positive force density f/r^3 . The relation between the pressure p (calculated within the Friedmann model) and the force density is a simple derivation with respect to r the space variable. And the derivation of a negative pressure leads to a positive force density.

Keywords: existence of dark matter; threedimensional curved universe

INTRODUCTION

The question which is arising since the observation of the acceleration of the expansion of the universe is: do we really have to revise the Cosmological Standard Model? Indeed, type Ia Supernovae (SNeIa), anisotropies in the cosmic microwave background radiation (CMBR), and matter power spectrum inferred from large galaxy surveys suggest a revision of this model. Up to now, the most commonly accepted theory implies that cold dark matter (CDM) represents 25.8% of the universe matter content and dark energy 69.4% of the energy content (last Planck's results). This theory is explained within the Λ CDM model. But, a model would be to analyze the behavior of time during the expansion of the universe. Previous publications suggest that time could be a function of lengths: indeed, by making a simple dimensional analysis of Einstein's field equations, one finds that the dimension of time equals the dimension of a length. A possible explanation of the acceleration of the expansion of the universe would be to consider cosmic time as a function of the radius of curvature of the universe.

THEORY

Let us make the corresponding calculation within the frame of the Roberston Walker model in the case of the homogeneous vacuum dominated universe. The two equations (Friedmann equations) in this model are:

$$\left(\frac{\dot{a}}{a}\right)^2 + \frac{kc^2}{a^2} - \frac{\Lambda c^2}{3} = \frac{8\pi G}{3}\rho \quad (1)$$

and

$$\frac{\ddot{a}}{a} = -\frac{4\pi G}{3}\left(\rho + \frac{3p}{c^2}\right) + \frac{\Lambda c^2}{3} \quad (2)$$

The cosmological constant term can be omitted if we make the following replacement

$$\rho \rightarrow \rho + \frac{\Lambda c^2}{8\pi G} \quad (3)$$

$$p \rightarrow p - \frac{\Lambda c^4}{8\pi G} \quad (4)$$

Therefore the cosmological constant can be interpreted as arising from a form of energy which has negative pressure, equal in magnitude to its (positive) energy density:

$$p = -\rho c^2 \quad (5)$$

Such form of energy a generalization of the notion of a cosmological constant is known as dark energy.

In fact, in order to get a term which causes an acceleration of the universe expansion, it is enough to have a scalar field which satisfies

$$p < -\frac{\rho c^2}{3} \quad (6)$$

Another theory to explain equation (6) is to analyze the pressure p .

I make here the hypothesis that our three dimensional universe with physical laws is embedded in a fourdimensional space where no physical law exist. This is consistent with my former publication [1, 2].

In the Friedmann model, the pressure p is negative. But the dimensions of p are

$$f/r^2 \quad (7)$$

where f is a constant force (the force due to the energy of vacuum) and r^2 is a twodimensional surface. If our universe is threedimensional, the pressure would write

$$f/r^3 \quad (8)$$

where r^3 is the hypersurface of our universe (which corresponds to the universe at time t). To obtain (7), one has to integrate (8) over r , which leads to a negative pressure.

Indeed, the relation between the pressure p and what we call the force density (the force f divided by a threedimensional surface r^3) is:

$$-2\frac{f}{r^2} = \int \frac{f}{r^3} dr \quad (9)$$

So, if the pressure $p = f/r^2$ calculated within the Friedmann equations is negative (in the case of a vacuum dominated universe), the corresponding force density f/r^3 is positive. This seems logical as the energy of vacuum is positive and the force necessary to accelerate the expansion of the universe has to be applied on a threedimensional hypersurface. Indeed, our universe is threedimensional and curved. The hypersurface of the universe corresponds to the universe at a given comoving time t . The 'force' of the vacuum can only account for the acceleration of the expansion of the universe if applied to its hypersurface (which is threedimensional).

In conclusion the pressure $p = f/r^2$ is negative but the force density f/r^3 is positive.

CONCLUSION

The fact that the pressure p in the second Friedmann equation is negative can be explained by the dimensions of p itself. Indeed, p is a force divided by a twodimensional surface. While only a force divided by a threedimensional surface (a force density) can account for the acceleration of the expansion of the universe. And that because the hypersurface of our universe is threedimensional and curved. The relation between the pressure $p = f/r^2$ and the force density f/r^3 is a simple derivation.
