ABSTRACT

Automatic labelling and identification of cerebral structure, such as cortical sulci, are useful in neurology, surgery planning, etc… In this paper, a method to detect the valley of the cortical sulci is presented. The aim of the method is to achieve the sulci medial surface. The method applied on MRI data, is based on geometrical features (curvature) which doesn’t require the accurate segmentation of the cerebral cortex. We use a sub-voxel precision tracking. The minimum curvature vector in each point allows successive displacement along the valley of sulci. Partial derivatives provide the differential characteristics.

1. INTRODUCTION

Human cortical sulci identification on 3D image is used in neurology, surgical planning, human brain mapping… Cortical sulci are landmarks and represent gross morphology to localise anatomical structures and functional areas with respect to these landmarks. Sulci are deep cortical folds and previous works are the automatic labelling of the superficial trace of the sulci on the surface of the brain [3]. This paper presents a method to detect the deep cortical fold without an accurate segmentation of brain tissue (white matter, grey matter, cerebro-spinal fluid), using curvature features. In fig. 1, an interactive drawing of the medial surface of sulci is superimposed with the MRI slice. Unlike works which start from the outer edge of sulcus to go toward the valley [5], we want to propagate the valley toward the outer edge, in the opposite path [6]. Then, the sulcus valley detection is an important stage of the process. This detection is obtained by 3 dimensions curve tracking.

2. SULCI AND CURVATURE

Cortical sulci and gyri define gross anatomical landmarks on the surface of the cerebral cortex. Sulci represent the cortical folds. The parts between these convolutions are the gyri. Physical limits between sulci and gyri are not precisely defined, but respectively square with concave and convex parts. Curvature is then used to separate sulci and gyri. In 3D images, at each point A of an iso-surface \( I \), there are two principal directions \( \vec{t}_1 \) and \( \vec{t}_2 \) in tangent plane of \( I \), which correspond to the maximal and minimal curvature \( k_1 \) and \( k_2 \) (fig. 2) [4].

\[
K = k_1 k_2 \\
S = \frac{k_1 + k_2}{2}
\]

From differential characteristics of the image we compute \( K \) and \( S \) as following:
\[
K = \frac{1}{h^2} \left( I_x^2 (I_{yy} I_{zz} - I_{yz}^2) + 2 I_y I_z (I_{xz} I_{xy} - I_{xz} I_{yz}) + I_y^2 (I_{zz} I_{yy} - I_{xz}^2) + 2 I_z I_x (I_{xy} I_{yz} - I_{xz} I_{yy}) + I_z^2 (I_{xx} I_{zz} - I_{xz}^2) + 2 I_x I_y (I_{xz} I_{yz} - I_{xy} I_{yy}) \right)
\]

\[
S = \frac{1}{2h^2} \left( I_x^2 (I_{yy} + I_{zz}) - 2 I_y I_z I_{yz} + I_y^2 (I_{zz} + I_{xx}) - 2 I_z I_x I_{xz} + I_z^2 (I_{xx} + I_{yy}) - 2 I_x I_y I_{xy} \right)
\]

with \( h = I_x^2 + I_y^2 + I_z^2 \)

and

\[
I_{a,b}^m = \frac{\partial^{n+m} (G(a,b) \otimes I)}{\partial a^n \partial b^m}
\]

where \( G(a,b) = \frac{1}{\sigma \sqrt{2\pi}} e^{-\frac{a^2+b^2}{2\sigma^2}} \)

and \( \otimes \) the convolution operator.

\( k_1 \) and \( k_2 \) are then obtained by:

\[
k_{1,2} = S \pm \sqrt{S^2 - K}
\]

and directions \( \vec{t}_1 \) and \( \vec{t}_2 \) by:

\[
\vec{t}_{1,2} = \vec{a} \pm \sqrt{S^2 - K} \beta
\]

with \( \beta = (I_z - I_y, I_x - I_z, I_y - I_x) \) and

\[
\vec{a} \cdot \vec{x} = -\frac{1}{2h^{3/2}} \left( -2 I_y^3 I_{xy} + I_y^3 I_{yz} + 2 I_x^3 I_{xz} - 2 I_y^2 I_x I_{xy} + 2 I_x^2 I_y I_{xy} + 2 I_x^2 I_z I_{yz} - 2 I_y^2 I_z I_{xz} - 2 I_z^2 I_y I_{yz} + I_z^2 I_{xz} - I_y^2 I_{xx} - I_x^2 I_{yy} - I_z^2 I_{zz} + 2 I_z^2 I_x I_{yz} - 2 I_z^2 I_y I_{xz} + 2 I_x^2 I_z I_{yz} - 2 I_z^2 I_y I_{xz} - 2 I_x^2 I_x I_{yy} - 2 I_x^2 I_y I_{xz} + 2 I_x^2 I_z I_{yz} + 2 I_x^2 I_y I_{yz} - 2 I_x^2 I_z I_{xz} + 2 I_y^2 I_y I_{yz} - 2 I_y^2 I_x I_{xy} + 2 I_x^2 I_z I_{yz} \right)
\]

The \( y \) and \( z \) components of the vector \( \vec{a} \) are obtained by circular permutations of \( x,y \) and \( z \).

In case of sulci, \( \vec{t}_2 \) is along the valley. \( \vec{t}_2 \) will be used to follow the roof of sulci.

### 3. 3D CURVE TRACKING

Sulci have to be represented as a parametric 3D curve, i.e. an ordered set of connected voxels \((x(t),y(t),z(t))\). The basic idea of the tracking process is to use the \( \vec{t}_2 \) vector, which give the direction of the next voxel for each point of the surface.

To achieve an iterative crest line tracking, we need three notions:

- Starting points, origin of 3D curve.
- A function which determines the next point of the curve, in local neighbourhood.
- A condition to stop the iterative process.

#### 3.1. Discrete case

In the 3D discrete grid of the image we have noticed two main problems.

- In the direction of \( \vec{t}_2 \), a voxel \( V \) is chosen. Now, there is only a finite number (26) of directions defined by the local neighbourhood.
- Local curvature values are different from real values.

These two points lead the tracking process to fail to detect and to extract the sulci.
3.2. Subvoxel tracking

Since discrete derivative values are not accurate enough to ensure a precise detection, we used a sub-voxel tracking. Voxel notion is replaced by point notion, since the tracking goes step by step with a step smaller than voxel. The point positions are not in the grid of volume, so the differential characteristics are computed by trilinear or better interpolation.

Starting points

First, MLvv operator [1][2], similar to average curvature, is computed. Negative values of MLvv are kept by thresholding. The image is labelled and each connected component is a volume representing one sulcus. The starting points are the voxels with the highest curvature in each connected component.

Following points

Several functions to determine the next point have been examined. 3 of them are now presented.

Case 1:

From a point \( P \), the next point \( N \) is the point in direction of the \( \tilde{t}_2 \) vector, at the distance \( \text{step} \). This method is adequate in case of simple structures. Fig. 4 presents the results on an ellipsoidal structure. The first point of the tracking has been manually chosen. The result is the expected crest line.

\[
\vec{d} = a\vec{\tilde{t}}_2 + (1-a)\vec{r}
\]

where

\[
\vec{r} = \frac{\sum_{i=1}^{8} PM_i \cdot C_i}{\sum_{i=1}^{8} \|PM_i\|}
\]

\( M_i \) are the 8 neighbour voxels of \( P \), \( C_i \) their respective curvature. This method is adequate with large object without very high curvature values and good SNR. With large curvature, \( \tilde{t}_2 \) and \( \vec{r} \) are sometimes opposite, and \( \vec{d} \) null. So the tracking process stops before the real termination

Case 3:

To avoid the previous problem, \( \vec{r} \) belong to the normal plan of \( \tilde{t}_2 \) (Fig.5). The effect of \( \tilde{t}_2 \) must be predominant

\[
\vec{r} = \sum_{i=1}^{8} \frac{PM_i \cdot C_i}{\sum_{i=1}^{8} \|PM_i\|}
\]

Stopping conditions

This process is stopped when:

- The next voxel is in a gyri area (positive average curvature value).
- Umbilical area is reached: the principal curvatures \( K_1 \) and \( K_2 \) are equal, \( \tilde{t}_1 \) and \( \tilde{t}_2 \) are not defined in differential geometry.
- The curvatures are not defined: in area of null gradient values.
- A junction with an other sulcus.

4. RESULTS

MRI of healthy volunteers were acquired on a 1.5 Tesla GE Signa scanner using a SPGR sequence (124x256x256 voxels, 1.3 mm3).
All the lines corresponding to the sulci valley on a single hemisphere of a brain are visualized on Fig. 7. The bottom image shows the results of multiple sulci superimposed with a segmentation of the brain.

5. CONCLUSION

We have presented a method to extract roof of sulci with a sub-voxel precision. This method uses MRI brain data without accurate segmentation of the cerebral cortex. Roof of sulci are represented as 3D parametric curve, these curves are easy to statistically handle (i.e. average curve, standard deviation) and are used to define an atlas of cerebral sulci.
