ABSTRACT

TV-like constraints/regularizations are useful tools in variational methods for multicomponent image restoration. In this paper, we design more sophisticated non-local TV constraints which are derived from the structure tensor. The proposed approach allows us to measure the non-local variations, jointly for the different components, through various \(\ell_{1,p}\) matrix norms with \(p \geq 1\). The related convex constrained optimization problems are solved through a novel epigraphical projection method. This formulation can be efficiently implemented thanks to the flexibility offered by recent primal-dual proximal algorithms. Experiments carried out for color images demonstrate the interest of considering a Non-Local Structure Tensor TV and show that the proposed epigraphical projection method leads to significant improvements in terms of convergence speed over existing numerical solutions.

Index Terms— Convex optimization, color image restoration, non-local total variation, structure tensor, singular value decomposition.

1. INTRODUCTION

This work deals with the restoration of multicomponent images, such as color images, by adopting a constrained convex optimization approach. Such a formulation may be preferred to a regularized one since it has been recognized for a long time that incorporating constraints directly on the solution often facilitates the choice of the involved parameters [1, 2, 3, 4, 5]. Indeed, the constraint bounds are usually related to some physical properties of the target solution or to some knowledge of the degradation process, e.g. the noise statistical properties. One of the difficulties of constrained approaches is however that a closed form of the projection onto the considered constraint set is not always available. Closed forms are known for convex sets such as \(\ell_2\)-balls, hypercubes defining dynamics range constraints, or half-spaces. However, more sophisticated constraints are usually necessary in order to efficiently restore multicomponent images. Taking advantage of the flexibility offered by recent proximal algorithms, we propose an epigraphical method allowing us to address a wide class of convex constraints.

The quality of the results obtained through a variational approach strongly depends on the ability to model the regularity present in images. Since natural images are often piecewise smooth, popular regularization models tend to penalize the image gradient. In this context, Total Variation (TV) [6] has emerged as a simple, yet successful, convex optimization tool. However, TV fails to preserve textures, details and fine structures, because they are hardly distinguishable from noise. To improve this behaviour, the TV model has been extended by using a non-locality principle [7]. Another approach to overcome these limitations is to replace the gradient operator with a frame representation which yields a more suitable sparse representation of the image [8]. The connections between these two different approaches have been studied in [9]. It is still unclear which approach leads to the best results. However, there is some evidences that Non-Local (NL) TV may perform better in some image restoration tasks [10, 11]. We thus focus our attention on NLT-based constraints, although our proposed algorithm is quite general and it can also be adapted to frame-based approaches.

Related work and motivations The extension of TV-based models to multicomponent images is, in general, non-trivial. A first approach consists of computing TV channel-by-channel and then summing up the resulting smoothness measures [12, 13, 14, 15, 16]. Since there is no coupling of the components, this approach may potentially lead to component smearing and loss of edges across components. An alternative way is to process the components jointly, so as to better reveal details and features that are not visible in each of the components considered separately. This approach naturally arises when the gradient of a multicomponent image is thought of as a structure tensor [17, 18, 19, 20, 21, 22]. A concise review of both frameworks can be found in [22].

The algorithmic solutions proposed in the aforementioned works are mostly based on PDEs [18, 19, 12, 20, 21], projected gradient methods [14, 15, 16] or proximal algorithms such as FISTA or Chambolle-Pock primal-dual technique [22]. However, to the best of our knowledge, there does not exist an
We introduce the proposed NL structure tensor constrained optimization. To do so, for every \( \ell \in \{1, \ldots, N\} \), let us define the matrix
\[
X^{(\ell)} = (\omega_{t,n}(x_i^{(\ell)} - x_{i_0}^{(n)}))_{n \in N_\ell, 1 \leq i \leq R} \in \mathbb{R}^{M_\ell \times R}
\] (3)
where \( N_\ell \) is a possibly non-local neighborhood of \( \ell \) and \( M_\ell \) denotes its size. Methods for building such a neighborhood and setting the associated weights \((\omega_{t,n})_{n \in N_\ell} \in [0, +\infty)\) are described in [25, 26, 27, 28]. The resulting ST-NLTV constraint is
\[
g(x) = \sum_{\ell=1}^N \|X^{(\ell)}\|_p,
\]
(4)
where \( \| \cdot \|_p \) denotes the Schatten \( p \)-norm, with \( p \geq 1 \). Denoting by \( \sigma_{X^{(\ell)}} = (\sigma_{\ell,n}^{(m)})_{1 \leq m \leq \min\{M_\ell, R\}} \) the singular values of \( X^{(\ell)} \) ordered in decreasing order, the case \( p \in [1, +\infty) \) yields
\[
g(x) = \sum_{\ell=1}^N \left( \sum_{m=1}^{\min\{M_\ell, R\}} (\sigma_{\ell,n}^{(m)})^p \right)^{1/p},
\]
(5)
and \( p = +\infty \) leads to
\[
g(x) = \sum_{\ell=1}^N \sigma_{X^{(\ell)}}^{(1)}.
\]
(6)
When \( p = 1 \), the Schatten norm reduces to the nuclear norm.

Note that the Structure Tensor TV (ST-TV) proposed in [22] is a special case of (4) that arises when, for every \( \ell \in \{1, \ldots, N\} \), \( M_\ell = 2 \), \( N_\ell \) includes horizontal/vertical nearest neighbors, and, for every \( n \in N_\ell \), \( \omega_{t,n} = 1 \).

\section{ALGORITHMIC SOLUTION}

Within the proposed constrained optimization framework, Problem (2) can be reformulated as follows:
\[
\text{minimize } \quad f(Ax, z) \quad \text{s.t. } \quad \begin{cases} x \in C, \\ g(x) \leq \eta, \end{cases}
\]
(7)
where the set \( C \subset (\mathbb{R}^N)^R \) can be used for example to constrain the dynamics range of the signal to be recovered. \( F \) is the linear operator defined as
\[
F: x \mapsto [F_1 x \ldots F_N x]
\]
(8)
where, for every \( \ell \in \{1, \ldots, N\} \), \( F_\ell \) is the linear operator that maps \( x \in (\mathbb{R}^N)^R \) to the matrix \( X^{(\ell)} \in \mathbb{R}^{M_\ell \times R} \) defined in (3). Hereabove, \( D \) is the closed convex set defined as
\[
D = \{ X = [X^{(1)}^T \ldots X^{(N)}^T]^T \in \mathbb{R}^{M \times R} \mid \sum_{\ell=1}^N \|X^{(\ell)}\|_p \leq \eta \},
\]
(9)
with \( M = M_1 + \cdots + M_N \).
In recent works, iterative procedures have been proposed to deal with an $\ell_{1,2}$-ball constraint [23] or an $\ell_{1,\infty}$-ball constraint [24]. Similar techniques can be used to compute the projection onto $D$, but a more efficient method consists of using the epigraphical splitting method proposed in [28]. More precisely, we introduce an auxiliary vector $\zeta = (\zeta^{(\ell)})_{1 \leq \ell \leq N} \in \mathbb{R}^N$ in Problem (7) and decompose the constraint $D$ in two convex sets: a union of epigraphs

$$E = \{(X, \zeta) \in \mathbb{R}^{M \times R} \times \mathbb{R}^N \mid \forall \ell \in \{1, \ldots, N\} \quad (X^{(\ell)}, \zeta^{(\ell)}) \in \text{epi} \| \cdot \|_p\},$$

and a closed half-space

$$W = \{\zeta \in \mathbb{R}^N \mid 1_N^T \zeta \leq \eta\},$$

with $1_N = (1, \ldots, 1)^T \in \mathbb{R}^N$. By using the proposed epigraphical splitting method, Problem (7) can be recast as

$$\begin{align*}
\text{minimize} & \quad f(Ax, z) \quad \text{s.t.} \quad \begin{cases} x \in C, \\
(F \, x, \zeta) \in E, \\
\zeta \in W.
\end{cases}
\end{align*}$$

The projection onto $W$ is trivial, while the projection onto $E$ is given by the following new result:

**Proposition 3.1** Let $\ell \in \{1, \ldots, N\}$ and let $X^{(\ell)} \in \mathbb{R}^{M \times R}$. Let $U^{(\ell)} S^{(\ell)} (V^{(\ell)})^T$ be the Singular Value Decomposition of $X^{(\ell)}$ where $(U^{(\ell)})^T U^{(\ell)} = I$, $(V^{(\ell)})^T V^{(\ell)} = I$ and $S^{(\ell)} = \text{Diag}(s^{(\ell)})$ with $s^{(\ell)} = (s^{(m)}_{X^{(\ell)}})_{1 \leq m \leq \min\{M, R\}}$. Then,

$$\left(U^{(\ell)} T^{(\ell)} (V^{(\ell)})^T, \theta^{(\ell)}\right) = P_{\text{epi} \| \cdot \|_p} (X^{(\ell)}, \zeta^{(\ell)}),$$

where $T^{(\ell)} = \text{Diag}(t^{(\ell)})$ and

$$\left(t^{(\ell)}, \theta^{(\ell)}\right) = P_{\text{epi} \| \cdot \|_p} (s^{(\ell)}, \zeta^{(\ell)}).$$

The above result shows that the projection onto the epigraph of the $\ell_{1,p}$ matrix norm can be deduced from the projection onto the $\ell_{1,p}$ vector norm. It turns out that closed form expressions of the latter projection exist when $p \in \{1, 2, +\infty\}$ [28]. For example, for every $(s^{(\ell)}, \zeta^{(\ell)}) \in \mathbb{R}^{\min\{M, R\}} \times \mathbb{R}$,

$$P_{\text{epi} \| \cdot \|_2} (s^{(\ell)}, \zeta^{(\ell)}) = \begin{cases} (0, 0), & \text{if } \|s^{(\ell)}\|_2 < -\zeta^{(\ell)}, \\
(s^{(\ell)}, \zeta^{(\ell)}), & \text{if } \|s^{(\ell)}\|_2 < \zeta^{(\ell)}, \\
\beta^{(\ell)} (s^{(\ell)}, \|s^{(\ell)}\|_2), & \text{otherwise},
\end{cases}$$

where $\beta^{(\ell)} = \frac{1}{2} \left(1 + \frac{\zeta^{(\ell)}}{\|s^{(\ell)}\|_2}\right)$. Moreover,

$$P_{\text{epi} \| \cdot \|_{\infty}} (s^{(\ell)}, \zeta^{(\ell)}) = (t^{(\ell)}, \theta^{(\ell)}),$$

where, for every $t^{(\ell)} = (t^{(\ell,m)})_{1 \leq m \leq \min\{M, R\}} \in \mathbb{R}^{\min\{M, R\}}$,

$$t^{(\ell,m)} = \min \left\{ \sigma^{(m)}_{X^{(\ell)}}, \theta^{(\ell)} \right\},$$

$$\theta^{(\ell)} = \max \left\{ \zeta^{(\ell)} + \sum_{k=1}^{\min\{M, R\}} \nu^{(\ell,k)} \cdot k, 0 \right\} \frac{\min\{M, R\} - k + 2}{\min\{M, R\} - k + 2}.$$  

Hereabove, $(\nu^{(\ell,k)})_{1 \leq k \leq \min\{M, R\}}$ is a sequence of reals obtained by sorting $(\sigma^{(m)}_{X^{(\ell)}})_{1 \leq m \leq \min\{M, R\}}$ in ascending order (by setting $\nu^{(\ell,0)} = -\infty$ and $\nu^{(\ell,\min\{M, R\}+1)} = +\infty$), and $\bar{F}$ is the unique integer in $\{1, \ldots, \min\{M, R\} + 1\}$ such that

$$\nu^{(\ell,\bar{F} - 1)} < \zeta^{(\ell)} + \sum_{k=\bar{F}}^{\min\{M, R\}} \nu^{(\ell,k)} \leq \nu^{(\ell,\bar{F})}.$$  

Note that the computation of the SVD can be avoided when $p = 2$.

**4. NUMERICAL RESULTS**

In our experiments, the matrix $A$ is a decimated convolution which applies to each component an uniform blur followed by a random decimation. We have thus $R = S$. The operator $B$ corresponds to an additive zero-mean white Gaussian noise with standard deviation $\alpha$. The fidelity term related to the noise neg-log-likelihood is $f = \|A \cdot -z\|_2^2$.

The experiments are focused on color imaging, i.e. the case $R = 3$. While it is common for color imaging to work in a luminance-chrominance space (such as YCbCr) or a perceptually uniform space (such as CIE Lab), the random decimation prevents us from following this approach. Indeed, the problem is that pixels having missing colors cannot be correctly projected onto a different color space. Therefore, the experiments are conducted in the RGB color space. The dynamics range constraint set $C$ imposes that the pixel values belong to $[0, 255]$.

In order to solve Problem (12), we employ the primal-dual M+LFBF algorithm recently proposed in [29], which is able to address a wide class of convex optimization problems without requiring any matrix inversion. It offers a good performance and robustness to numerical errors. Its convergence is guaranteed (under weak conditions) and its structure makes it suitable for implementation on highly parallel architectures.

In Fig. 1, we collect the results obtained on the color image airplane ($N = 512 \times 512$) by using the proposed ST-NLTV (cf. Section 2) and ST-TV [22]. The latter method can be viewed as a particular case of the former one. CC-TV and CC-NLTV refer to a channel separable constraint on $\sum_{i=1}^{R} \sum_{\ell=1}^{N} \|X^{(\ell)}_{i}\|_p$, where $X^{(\ell)}_{i}$ denotes the $i$-th column vector of $X^{(\ell)}$ and $\| \cdot \|_p$ is the $\ell_p$ vector norm. In this example, the bound $\eta$ for each constraint was tuned in order to achieve the best SNR value.

The results demonstrate the interest of considering non-local structure tensor measures. Figs. 1b and 1c show the results obtained with CC-TV-$\ell_2$ and CC-NLTV-$\ell_2$. Although
NLTV better preserves edges and fine details, one can observe a color smearing in the reconstructed images. Figs. 1d and 1e illustrate the results obtained with ST-TV-\(\ell_2\) and ST-NLTV-\(\ell_2\). A significant reduction of color smearing can be noticed. In particular, Fig. 1e shows that combining the structure tensor with NLTV brings the advantages of both methods: preserved details and reduced color smearing. Furthermore, the comparison between the images displayed in the first and second rows indicates that the \(\ell_2\)-norm performs better than the \(\ell_\infty\)-norm.

Note that, according to our tests, the nuclear norm leads to poorer results than the \(\ell_\infty\)-norm.

Fig. 2 shows that the epigraphical approach (blue line) leads to a faster convergence than a direct projection method (red line). In particular, for TV-\(\ell_\infty\) and NLTV-\(\ell_\infty\), the convergence is about 10 to 40 times faster. The results refer to the airplane image cropped at 256 \(\times\) 256 (a similar behaviour was observed for other images of different sizes). The stopping criterion is set to \(\|x^{[n+1]} - x^{[n]}\|/\|x^{[n]}\| \leq 10^{-4}\) where \((x^{[n]}), n \in \mathbb{N}\) denotes the sequence generated by M+LFBF. For the \(\ell_{1,p}\)-ball projectors needed by the direct method, we used the software available on-line [23, 24]. Our codes were developed in Matlab R2011b (the operators \(F\) and \(F^\top\) being implemented in C using mex files) and all the programs executed on an Intel Xeon CPU at 2.80 GHz with 8 GB of RAM.

5. CONCLUSION

We have proposed a new epigraphical technique for solving constrained convex optimization problems arising in multicomponent image restoration. The obtained results demonstrate the advantages of using the structure tensor and non-local gradients in this context. We have also shown that an \(\ell_{1,p}\)-norm constitutes a good choice for defining smoothness constraints. Furthermore, our experiments indicate that the epigraphical method converges faster than the approach based on the direct computation of the projections via standard iterative solutions.
