Uniform Global Position Feedback Tracking Control of Mechanical Systems Without Friction

Antonio Loría

Abstract—We establish, as far as we know, the first proof of uniform global asymptotic stability for a mechanical system (Euler-Lagrange) in closed loop with a dynamic controller which makes use only of position measurements. The controller is fairly simple, it is reminiscent of the so-called Padé-Panja controller [20] where unavailable generalized velocities are replaced by approximate differentiation (dirty derivatives). The controller has been reported previously however, only semiglobal\(^1\) asymptotic stability has been established so far. The novelty of this paper relies in establishing a global property as well as in the method of proof, which does not follow Lyapunov’s. However, the problem of finding a strict control Lyapunov function remains open.

I. INTRODUCTION

We study Euler-Lagrange systems, given by the equation

\[ D(q) \ddot{q} + C(q, \dot{q}) \dot{q} + g(q) = u \]  

where \( q \in \mathbb{R}^n \) denotes the generalized positions, \( \dot{q} \) denotes the generalized velocities, \( D : \mathbb{R}^n \rightarrow \mathbb{R}^{n \times n} \) corresponds to the inertia matrix function, \( C : \mathbb{R}^n \times \mathbb{R}^n \rightarrow \mathbb{R}^{n \times n} \) corresponds to the Coriolis and centrifugal forces matrix, \( g : \mathbb{R}^n \rightarrow \mathbb{R}^n \) represents the vector of forces which are derived from the potential energy function \( U : \mathbb{R} \rightarrow \mathbb{R} \) i.e., \( g(q) := \partial U \bigg/ \partial q \) and \( u \in \mathbb{R}^n \) is the vector of control inputs.

All functions are smooth in their arguments. The author in [4] invokes Tychonov’s theorem on singularly perturbed systems to show uniform global asymptotic stability provided that the unique pole of the controller (for the system of augmented dimension) is not implementable via output-feedback since it must satisfy a mechanical constraint whose verification requires the knowledge of the unmeasured velocities. During the preparation of this final manuscript we became aware of [23] where the author presents a global result for Hamiltonian systems which relies on a clever but intricate observer-design and a change of coordinates that involves the computation of the square root of \( D(q)^{-1} \).

Other works focus on robot tracking control. For instance, the classic paper [4] presented a proof of uniform asymptotic stability using Kelly’s controller [8] originally proposed for set-point control. The author in [4] invokes Tychonov’s theorem on singularly perturbed systems to show uniform global asymptotic stability provided that the unique pole of the dirty-derivatives filter used in [8] is placed at \( -\infty \) that is, the result actually establishes semi-global asymptotic stability. The same property is achieved via Lyapunov’s direct method in [12]. Relying on the practically reasonable but theoretically restrictive assumption that the system possesses (natural) viscous friction which induces damping, the authors in [18] established global asymptotic stability. That is, the model considered is

\[ D(q) \ddot{q} + C(q, \dot{q}) \dot{q} + F \dot{q} + g(q) = u \]  

where \( F \) is symmetric positive definite. However, under these conditions, it is direct to extend the stability property from semi-global to global, for a number of results in the literature.

In the last 30 years or so there have been numerous attempts to solve the problem mentioned above, as a particular paradigm of dynamic output feedback control of nonlinear systems. See for instance [16] and other works by the same authors on output feedback linearization that are collected in [15]. In a similar train of thought we find methods that rely on the ability to perform a coordinate transformation of system (1) into models that are linear in the unmeasured velocities. See for instance the work of G. Besançon –[1], [2] and subsequent references, including [13]. However, it has been long recognized that such transformations are inapplicable to many physical systems; even to simple two-degrees-of-freedom planar robots with revolute joints –see [25]. In the article [11] we intend to circumvent the difficulties encountered in preceding literature by exploring a change of coordinates which yields a non-minimal realization. However, the resulting controller (for the system of augmented dimension) is not implementable via output-feedback since it must satisfy a mechanical constraint whose verification requires the knowledge of the unmeasured velocities. During the preparation of this final manuscript we became aware of [23] where the author presents a global result for Hamiltonian systems which relies on a clever but intricate observer-design and a change of coordinates that involves the computation of the square root of \( D(q)^{-1} \).

\(^1\)That is, the domain of attraction may be arbitrarily enlarged by enlarging the control gains.
cannot be stabilized globally by dynamic output feedback with output $q$. The obstacle is that the system does not possess the unboundedness observability property that is, the solution $[q(t), q(t')]$ may escape to infinity even for bounded values of $q(t)$. Notice that this is not the case of Lagrangian systems which possess the structural property of skew-symmetry of the matrix $D(q) = 2C(q, q)$. Indeed, uniform global asymptotic stability of systems

$$d(q) \dot{q} + c(q)q^2 + g(q) = u$$

is established in [10] provided that $d(q) = 2c(q)q^2$. As a matter of fact this is probably the only article that presents a dynamic output-feedback controller for Euler-Lagrange systems together with a strict Lyapunov function albeit for one-degree-of-freedom systems. The extension to the case of $n$-degree-of-freedom systems has not been obtained yet; attempts include [27], [3] however, the controller from [27] is guaranteed (in the non-adaptive case, only) to achieve uniform asymptotic stability for any system's initial conditions provided that the controller's trajectories lay in a forward-invariant set. Yet, the result in [27] relies on the restrictive assumption that the model includes viscous friction (of known magnitude in the non-adaptive case) i.e., as in (2) and that the forces derived from potential energy are bounded. The controller of [3] is not implementable without velocity measurements.

In summary, to the best of the author's knowledge establishing uniform global asymptotic stability remains open; roughly speaking, there are two types of results addressing this problem. Those based on Lyapunov's direct method and those which intended to exploit structural properties. In the first case, stability is global only with respect to part of the states—as in [27] or is semiglobal—as in [4], [12] etc. In the second case, the structural assumptions needed to perform convenient changes of coordinates do not hold for EL systems—cf. [25].

The rest of the paper is organized as follows. For the sake of clarity we recall basic stability definitions in Section II. In Section III we present our main result and in Section IV.

## II. Preliminaries

To remove all possible ambiguity we start by recalling a few definitions of stability from [6] and some statements which are either known or are re-stated in an original manner, for the purposes of this article. Consider the dynamic system

$$\dot{x} = f(t, x), \quad x \in \mathbb{R}^n, t \in \mathbb{R}_{\geq 0}. \quad (3)$$

We denote by $x(t, t_0, x_0)$ or when the context is clear by $x(t)$, the solutions of (3) with initial times $t_0 \in \mathbb{R}_{\geq 0}$ and initial states $x_0 \in \mathbb{R}$ that is, we have $x(t, t_0, x_0) = x_0$. Recall that a continuous function $\alpha : \mathbb{R}_{\geq 0} \to \mathbb{R}_{\geq 0}$ is of class $K$ if it is strictly increasing and $\alpha(0) = 0$, a continuous function $\sigma : \mathbb{R}_{\geq 0} \to \mathbb{R}_{\geq 0}$ is of class $L$ if it is strictly decreasing and $\sigma(s) \to 0$ as $s \to \infty$; a continuous function $\beta : \mathbb{R}_{\geq 0} \times \mathbb{R}_{\geq 0} \to \mathbb{R}_{\geq 0}$ is of class $K\mathcal{L}$ if $\beta(r, \cdot) \in \mathcal{L}$ and $\beta(\cdot, s) \in K$; a continuous function $\alpha : \mathbb{R}_{\geq 0} \to \mathbb{R}_{\geq 0}$ is of class $K_{\infty}$ if $\alpha \in K$ and $\alpha(s) \to \infty$ as $s \to \infty$. We denote by $|\cdot|$, the Euclidean norm of vectors (or any other compatible norm) and the induced norm of matrices.

### Definition 1 (Uniform global boundedness)

The solutions of (3) are said to be uniformly globally bounded if there exist $\gamma \in K_{\infty}$ and $c > 0$ such that, for all $(t_0, x_0) \in \mathbb{R}_{\geq 0} \times \mathbb{R}^n$ each solution $x(t, t_0, x_0)$ satisfies

$$|x(t, t_0, x_0)| \leq \gamma(|x_0|) + c \quad \forall t \geq t_0. \quad (4)$$

Note that for any $r$ there exists $R$ independent of $t_0$ such that $|x_0| \leq r$ implies that $|x(t, t_0, x_0)| \leq R$. This property is commonly established via auxiliary functions.

### Theorem 1

Let $V : \mathbb{R}_{\geq 0} \times \mathbb{R}^n \to \mathbb{R}_{\geq 0}$ be continuously differentiable; $\alpha_1, \alpha_2$ be functions of class $K_{\infty}$ and let $a \in \mathbb{R}$ and $c > 0$ be such that

$$\alpha_1(|x|) \geq V(t, x) \geq \alpha_2(|x|) + a \quad \forall (t, x) \in \mathbb{R}_{\geq 0} \times \mathbb{R}^n$$

Then, the solutions of (3) are uniformly globally bounded.

The following definition may be found in [6].

### Definition 2 (Uniform global stability)

The origin of system (3) is said to be uniformly globally stable if there exists $\gamma \in K_{\infty}$ such that for each $(t_0, x_0) \in \mathbb{R}_{\geq 0} \times \mathbb{R}^n$, each solution $x(t, t_0, x_0)$ satisfies

$$|x(t, t_0, x_0)| \leq \gamma(|x_0|) \quad \forall t \geq t_0. \quad (5)$$

Note that uniform global stability tantamounts to uniform stability plus uniform global boundedness.

### Theorem 2

Let the conditions of Theorem 1 hold for $a = c = 0$. Then, the origin of (3) is uniformly globally stable.

The proof of Theorem 1 is due to Persidskii [22] and appears in numerous textbooks.

### Definition 3 (Uniform global attractivity)

The origin of system (3) is said to be uniformly globally attractive if for each $r, \sigma > 0$ there exists $T > 0$ such that

$$|x_0| \leq r \implies |x(t, t_0, x_0)| \leq \sigma \quad \forall t \geq t_0 + T. \quad (6)$$

The proof follows along similar lines as [26, Theorem 25, p. 165].

### Definition 4 (Uniform Global Asymptotic Stability)

The origin of system (3) is said to be uniformly globally asymptotically stable if it is
uniformly stable;
the solutions are uniformly globally bounded;
the origin is uniformly globally attractive.

It is important to emphasize that only all three conditions in Definition 4 together, imply the existence of a class $\mathcal{K}\mathcal{L}$ function $\beta$ such that the solutions of (3) satisfy
\[ |x(t)| \leq \beta(|x_0|, t - t_0) \quad \forall t \geq t_0 \geq 0 \]
which leads to the construction of converse Lyapunov functions and in turn, implies robustness with respect to external perturbations but the latter cannot be concluded from uniform stability plus uniform global attractivity alone. Whence the importance of uniform global boundedness in nonlinear time-varying systems.

The following statement establishes uniform global asymptotic stability using integral conditions, in the spirit of Barbálat’s lemma however, we recall that the latter may not be used to establish uniform convergence.

**Lemma 1** [21] Let $F : \mathbb{R}_{\geq 0} \times \mathbb{R}^n \to \mathbb{R}^n$ be continuous. If the origin of the system $\dot{x} = F(t, x)$ is uniformly globally stable and there exists a continuous positive function $\gamma : \mathbb{R}^n \to \mathbb{R}_{\geq 0}$ and for each $r, \nu > 0$ there exists $\beta_{r, \nu} > 0$, such that for all $(t_0, x_0) \in \mathbb{R}_{\geq 0} \times B_r$, all solutions $x(t_0, x_0)$ and all $t \geq t_0$,
\[ \int_{t_0}^{t} |\gamma(x(\tau, t_0, x_0)) - \nu| \, d\tau \leq \beta_{r, \nu} \quad (7) \]
then the origin of the system $\dot{x} = F(t, x)$ is uniformly globally asymptotically stable.

### III. MAIN RESULT

The following assumptions are fairly standard in the literature of robot control but are also satisfied by a number of Euler-Lagrange systems such as electrical and electro-mechanical –see [19], as well as some marine systems –see [5]. In particular, these hypotheses hold for robot manipulators composed of revolute joints only or prismatic joints only.

**Assumption 1**

1) There exist positive real numbers $d_m$ and $d_M$ such that
\[ d_m \leq |D(q)| \leq d_M, \quad \forall q \in \mathbb{R}^n; \]

2) there exists $k_c > 0$ such that
\[ |C(x, y)| \leq k_c |y| \quad \forall x, y \in \mathbb{R}^n; \]
\[ C(x, y)z = C(x, z) \quad \forall x, y, z \in \mathbb{R}^n; \]

3) the matrix $D(q) - 2C(q, \dot{q})$ is skew symmetric.

**Definition 5 (global output-feedback tracking control)**

Consider the EL system (1). Suppose that only position measurements are available and that the properties enumerated in Assumption 1 hold. Furthermore, assume that the reference trajectory $t \mapsto q_d$ is of class $C^2$ and that there exists $k_\delta > 0$ such that
\[ \max \left\{ \sup_{t \geq 0} |q_d(t)|, \sup_{t \geq 0} |\dot{q}_d(t)|, \sup_{t \geq 0} |\ddot{q}_d(t)| \right\} \leq k_\delta. \quad (9) \]

Under these conditions, find a dynamic output-feedback controller
\[ \dot{q}_c = f(t, q_c, q) \quad (10a) \]
\[ u = u(t, q_c, q) \quad (10b) \]
such that the closed-loop system
\[ D(q)\ddot{q} + C(q, \dot{q})\dot{q} + g(q) = u(t, q_c, q) \quad (11) \]
has a unique equilibrium at
\[ (q_c - q_\delta, \dot{q}_c, \ddot{q}_c) = (0, 0, 0), \]
\[ \dot{q} := q - q_d(t), \quad \ddot{q} := \dot{q} - \ddot{q}_d(t) \]
where $q_\delta$ is a solution to (10) with $q \equiv q_d$, which is uniformly globally asymptotically stable.

**Theorem 3** Consider the system (1) under Assumption 1. Let $a, b, k_p$ and $k_d$ be positive constants satisfying
\[ \min \left\{ \frac{k_p}{a q^2 d_4}, \frac{k_d}{4 b d_M} \right\} > 1 \quad (12a) \]
\[ k_b(k_d - k_b k_\delta) > k_c k_\delta. \quad (12b) \]
where $k_b := a/b$ and consider the dynamic position-feedback controller
\[ \dot{q}_c = -a(q_c + b\dot{q}) \quad (13a) \]
\[ \dot{\vartheta} = q_c + b\dot{q} \quad (13b) \]
\[ u = -k_p\ddot{q} - k_d\dot{\vartheta} + D(q)\ddot{q}_d + C(q, \dot{q}_d)\dot{q}_d + g(q) \quad (13c) \]

Then, there exist $a^* \text{ and } b^* \text{ independent of the initial conditions such that if } a \geq a^*, b \geq b^* \text{ the origin } \{z = 0\} \text{ with } z := [\ddot{q}^T, \dot{\vartheta}^T, \dot{q}_c^T]^T \text{ is uniformly globally asymptotically stable.} \]

We show that there exist minimal values of the filter parameters $a$ and $b$ such that, provided that the controller gains satisfy (12), the origin is uniformly asymptotically stable for any initial conditions in $t_0, [\ddot{q}(t_0), \dot{\vartheta}(t_0), q_c(t_0)] \in \mathbb{R}_{\geq 0} \times \mathbb{R}^{3n}$. However, the proof is (unfortunately) not constructive in the sense that we do not use Lyapunov’s direct method.

**Remark 1** We stress that the controller (13) corresponds to that from [12] where semiglobal asymptotic stability is established. The controller is also reminiscent of that from [12] where semiglobal asymptotic stability is obtained by replacing $u$ from (13c) in (1) and subtracting $C(q, \ddot{q}_d)\ddot{q}$ to both sides of (13c) hence,
\[ D(q)\ddot{q} + [C(q, \ddot{q}) + C(q, \ddot{q}_d)]\dot{q} + k_p\ddot{q} + k_d\dot{\vartheta} = 0. \quad (14) \]

Now, for the purpose of analysis we differentiate (13b) and use (13a) to obtain
\[ \dot{\vartheta} = -a\dot{\vartheta} + b\ddot{q}. \quad (15) \]
We emphasize that (19) implies that for any \( t \in [\tau, \tau^\max) \) and \( a \geq a^* \),
\[
    b |\dot{q}(t)| \leq \Delta^* + a |\vartheta(t)|.
\]
Hence, defining \( v_1(t) := V_1(t, q(t), \dot{q}(t), \vartheta(t)) \) we obtain, from (17),
\[
    \dot{v}_1(t) \leq -\frac{a}{b} \left( k_d - \frac{a k_c k_D}{b} \right) |\vartheta(t)|^2 + k_c k_D \Delta^* \frac{\delta^2}{b^2} \tag{21}
\]
for all \( t \in [\tau, \tau^\max) \) and \( a \geq a^* \). Let \( b^* \geq \Delta^* \) then, for any \( b \geq b^* \)
\[
    \dot{v}_1(t) \leq -k_b (k_d - k_c k_D \Delta^*) |\vartheta(t)|^2 + k_c k_D \Delta^*. \tag{22}
\]
Now, assume that \( |\vartheta(t)| \to \infty \) as \( t \to \infty \) then, either \( |\vartheta(t)| \) grows unboundedly as \( t \to \infty \) or it remains bounded. In the first case, since (21) holds for any \( \tau^\max \) by continuity of solutions and since \( \Delta \) is independent of \( \tau^\max \) we can (if necessary) extend the interval so that for sufficiently large \( t \in [\tau, \tau^\max] \) we have \( |\vartheta(t)| \geq 1 \) so in view of (12b), \( \dot{v}_1(t) \leq 0 \) which implies that \( v_1(t) \) is bounded. Since \( V_1 \) is radially unbounded we also obtain that \( |x(t)| \) is uniformly bounded. Next, assume that \( |\vartheta(t)| \) is uniformly bounded for any \( t \) then, and either \( |\dot{q}(t)| \) or \( |\dot{q}(t)| \) (both) grow unboundedly. If \( |\dot{q}(t)| \) grows unboundedly it follows, in view of (15), that \( |\vartheta(t)| \to \infty \) and the previous reasoning applies again. Finally, consider the case that \( |x(t)| \to \infty \) due to the unbounded growth of \( |\dot{q}(t)| \) and consider the function \( V_2 : \mathbb{R}_{\geq 0} \times \mathbb{R}^{3n} \to \mathbb{R}_{\geq 0} \).
\[
    V_2(t, q, \dot{q}, \vartheta) = (\varepsilon_1 \dot{q} - \varepsilon_2 \vartheta)^T D(q + q_d)(\dot{q}) \tag{23}
\]
which in view of (14) and (15), satisfies
\[
    \dot{V}_2 = (\varepsilon_1 \dot{q} - \varepsilon_2 \vartheta)^T (\delta D(q) + C(q, \dot{q}) + C(q, \vartheta) \dot{q}) + \varepsilon_1 \dot{q}^T D(q) \dot{q} - \varepsilon_2 (\alpha \dot{q} + b \vartheta)^T D(q) \dot{q} \tag{24}
\]
Let \( R \) be an arbitrary positive number and define
\[
    \Omega := \{ x \in \mathbb{R}^{3n} : \dot{q} \in \mathbb{R}^n, \max\{|\dot{q}|, |\vartheta|\} \leq R \}.
\]
Then,
\[
    |\varepsilon_1 \dot{q}^T C(q, \dot{q}) \dot{q}| \leq \varepsilon_1 |\dot{q}| k_c (R + k_c) \tag{25a}
\]
\[
    |\varepsilon_2 \vartheta^T C(q, \vartheta) \dot{q}| \leq \varepsilon_2 |\vartheta| \dot{q} k_c (R + k_c) \tag{25b}
\]
and see (9). Under these conditions, note that the right-hand side of (24) may be upper bounded by a first-order polynomial of \( |\dot{q}| \) with coefficients which depend on \( |\dot{q}| \) and \( |\vartheta| \) which are bounded for all \( x \in \Omega \). Therefore, using Assumption 1 and (25) we see that there exist positive numbers \( c_1, c_2 \) such that, defining \( v_2(t) := V_2(t, q(t), \dot{q}(t), \vartheta(t)) \),
\[
    \dot{v}_2(t) \leq -c_1 k_2 |\dot{q}(t)|^2 + c_1 |\dot{q}(t)| + c_2 \tag{26}
\]
for all \( t \geq t_0 \) and \( x(t) \in \Omega \) that is, \( v_2(t) \) becomes negative as \( |\dot{q}(t)| \to \infty \).

Next, define \( V : \mathbb{R}_{\geq 0} \times \mathbb{R}^{3n} \to \mathbb{R} \),
\[
    V(t, x) := V_1(t, q(t), \dot{q}, \vartheta) + V_2(t, q(t), \dot{q}, \vartheta) \tag{27}
\]
which is positive definite for sufficiently large control gains, independently of the initial conditions. To see this, note that

\[
V(t, x) = \frac{1}{2} \begin{pmatrix} \dot{q}^T \\ \dot{\bar{q}} \end{pmatrix} \begin{pmatrix} k_p I & \varepsilon_1 D \\ \varepsilon_1 D^T & \frac{1}{2} D \end{pmatrix} \begin{pmatrix} \dot{q} \\ \dot{\bar{q}} \end{pmatrix} + \frac{1}{2} \begin{pmatrix} \dot{q}^T \\ \dot{\bar{q}} \end{pmatrix} \begin{pmatrix} \varepsilon_2 k_d I & -\varepsilon_2 D \\ -\varepsilon_2 D^T & \frac{1}{2} D \end{pmatrix} \begin{pmatrix} \dot{q} \\ \dot{\bar{q}} \end{pmatrix}
\]

where both matrices are positive definite respectively if

\[
k_p > \varepsilon_1^2, \quad k_d > \varepsilon_2^2
\]

which hold in view of (12a), since \(\varepsilon_1, \varepsilon_2 < 1\). It is also clear from Assumption 1.2, that \(V\) is proper since \(D\) is bounded. Using (21) and (26) we see that \(v(t) := V(t, x(t))\) satisfies

\[
v(t) \leq -\varepsilon_1 k_p |\dot{q}(t)|^2 + c_1 |\dot{q}(t)| + c_2
\]

for all \(x(t) \in \Omega, t \in [\tau, t^{\max}]\) and appropriate (innocuous) values of \(c_1\) and \(c_2\). If \(|\dot{q}(t)|\) grows unboundedly, there exists \(t \in [\tau, t^{\max}]\) (if necessary, replace \(t^{\max}\) with \(t^\ast\)) such that \(v(t) \leq 0\). By continuity we may extend \([\tau, t^{\max}]\) to \([\tau, \infty)\) and conclude that \(v(t)\) is uniformly bounded. Since \(x \mapsto V\) is proper |\(x(t)|\) is also uniformly bounded on \([\tau, \infty)\).

Using forward completeness again, we obtain uniform global boundedness on \([t_0, \infty)\).

This completes the proof of the proposition. □

The standing assumption in the following proposition is that the solutions are uniformly globally bounded, and which has been established above.

**Proposition 2** Consider the system (1) under the conditions of Theorem 3. Assume that for each \(r > 0\) there exists \(R(r)\) such that if \(x(t_0) \in B_r\), then \(x(t) \in B_R\) for all \(t \geq t_0\). Under these conditions, the origin is uniformly globally attractive.

**Proof.** Let the control gains be fixed according to (12). Consider a function \(V : \mathbb{R}_{\geq 0} \times B_R \rightarrow \mathbb{R}\) defined as in (27). Under Assumption 1 its total time-derivative along the trajectories of (14), (15) satisfies, for all \((t, x) \in \mathbb{R}_{\geq 0} \times B_R,

\[
\dot{V} \leq -\varepsilon_1 k_p |\dot{q}|^2 - \varepsilon_2 k_d m |\dot{q}|^2 - \frac{\varepsilon_2 b_d m |\dot{q}|^2}{8} - \left[\varepsilon_2 b_d m - \varepsilon_1 d M\right] |\dot{q}|^2 \\
- \frac{1}{2} \begin{bmatrix} |\dot{q}|^T & \varepsilon_1 k_p / 2 \\ \varepsilon_1 k_p / 2 & -\varepsilon_1 k_c (R + k_d) \end{bmatrix} \begin{bmatrix} |\dot{q}|^2 \\ \dot{q} \end{bmatrix} \\
- \frac{1}{2} \begin{bmatrix} |\dot{q}|^T & \varepsilon_2 k_p / 2 \\ \varepsilon_2 k_p / 2 & -\varepsilon_2 k_d m / 2 \end{bmatrix} \begin{bmatrix} |\dot{q}|^2 \\ \dot{q} \end{bmatrix} \\
- \frac{1}{2} \begin{bmatrix} |\dot{q}|^T & \varepsilon_2 b_d m / 2 \\ \varepsilon_2 b_d m / 2 & -\varepsilon_2 (k_c (R + k_c + k_d) + k_d^2 M) \end{bmatrix} \begin{bmatrix} |\dot{q}|^2 \\ \dot{q} \end{bmatrix} \\
- \frac{1}{2} \begin{bmatrix} |\dot{q}|^T & k_d a / 2b \\ k_d a / 2b & -k_d a / b \end{bmatrix} \begin{bmatrix} |\dot{q}|^2 \\ \dot{q} \end{bmatrix} \\
- \frac{k_d a}{4b} - \varepsilon_2 b_d m |\dot{q}|^2 + k_c k_d |\dot{q}|^2
\]

where “*” stands for the opposite element in the matrix with respect to the main diagonal. The factor of \(-|\dot{q}|^T\) in the third term above is positive, as well as the first matrix above is positive definite, if

\[
\frac{\varepsilon_2 b_d m}{4\varepsilon_1} \geq \frac{k_d^2 (R + k_d)^2}{k_p} + 2d M
\]

which holds for control gains independent of the initial conditions and of \(R\), if

\[
\frac{\varepsilon_2}{\varepsilon_1} = O\left(\frac{1}{R^2}\right).
\]

The second matrix is positive if

\[
\frac{\varepsilon_2 k_p k_d}{4b} \geq (\varepsilon_1 k_d + \varepsilon_2 k_p)^2
\]

which holds for sufficiently small values of \(\varepsilon_1\) and \(\varepsilon_2\). Finally, the third matrix is positive definite if

\[
\frac{k_d a}{4b} \geq \frac{(R + k_c k_d) k_c + k_d k_c + a d M}{2}
\]

which holds for sufficiently small values of

\[
\varepsilon_2 = O\left(\frac{1}{R^2}\right)
\]

which in turn, in view of (29), imposes that

\[
\varepsilon_1 = O\left(\frac{1}{R^2}\right).
\]

Hence, there exists \(c > 0\) such that

\[
\dot{V}(t, x) \leq -c |x|^2 + k_c k_d |\dot{q}|^2 \quad \forall (t, x) \in \mathbb{R}_{\geq 0} \times B_R.
\]

Now let the property of uniform global boundedness generate a number \(r > 0\) such that \(x(t_0) \in B_r\) implies that \(x(t) \in B_R\) for all \(t \geq t_0\) and for any \(t_0 \geq 0\). From (32) we have

\[
\dot{V}(t, x) \leq -[c |x(t)|^2 - \nu] \quad \forall (t, x_0) \in \mathbb{R}_{\geq 0} \times B_r.
\]

where \(\nu = k_c k_d R^2\). The claim follows observing that the previous development holds for arbitrary \(r > 0, \nu > 0\), integrating on both sides of (33) and invoking Lemma 1 with \(\gamma(s) = c |s|^2\). □

To the best of our knowledge, constructing a strict (control) Lyapunov function is an open problem which is illustrated by but not limited to the case of the controller (13). In a general nonlinear context, the state of the art in constructing Lyapunov functions for nonlinear time-varying systems relies on Lyapunov functions that have negative semi-definite derivatives —see [14]. That is, in the present context, the methods in the latter reference require that \(V_1 \leq 0\) as opposed to (17).

**IV. CONCLUSIONS**

The problem solved in this paper may not be overestimated; Euler-Lagrange systems are of a special kind in the sense that they belong to the class of systems studied in the seminal paper [17] for which it is proved that global output feedback stabilization is impossible, if not for the structural property that the Coriolis forces (the highly nonlinear terms) produce no work. We believe that the method of proof used here may unlock the path to solutions
to other problems such as global proportional-integral-derivative control\textsuperscript{3}. Further research is also undergoing to construct a control Lyapunov function with aim at realizing an to as adaptive version of the controller presented here.

Acknowledgements

The author is indebted to R. Ortega and E. Panteley for the arbitrarily large (but bounded) number of discussions on this problem during the last 20 and 15 years respectively, not withstanding this note.
