A SADDLE-POINT APPROACH TO THE MONGE-KANTOROVICH OPTIMAL TRANSPORT PROBLEM

CHRISTIAN LÉONARD

Abstract. The Monge-Kantorovich problem is revisited by means of a variant of the saddle-point method without appealing to $c$-conjugates. A new abstract characterization of the optimal plans is obtained in the case where the cost function takes infinite values. It leads us to new explicit sufficient and necessary optimality conditions. As by-products, we obtain a new proof of the well-known Kantorovich dual equality and an improvement of the convergence of the minimizing sequences.

1. INTRODUCTION

The Monge-Kantorovich problem is revisited by means of a variant of the saddle-point method derived in [12], without appealing to $c$-conjugates. A new abstract characterization of the optimal plans is obtained (Theorem 4.6) in the case where the cost function takes infinite values. It leads us to new explicit sufficient and necessary conditions of optimality which are stated in Theorems 1.13 and 1.15. As by-products, we obtain a new proof of the well-known Kantorovich dual equality and an improvement of the convergence of the minimizing sequences.

The Monge-Kantorovich transport problem. Let us take $A$ and $B$ two Polish (separable complete metric) spaces furnished with their respective Borel $\sigma$-fields, a lower semicontinuous (cost) function $c : A \times B \rightarrow [0, \infty]$ which may take infinite values and two probability measures $\mu \in \mathcal{P}_A$ and $\nu \in \mathcal{P}_B$ on $A$ and $B$. We denote $\mathcal{P}_A$, $\mathcal{P}_B$ and $\mathcal{P}_{AB}$ the sets of all Borel probability measures on $A$, $B$ and $A \times B$. The Monge-Kantorovich problem is

$$\text{minimize } \pi \in \mathcal{P}_{AB} \mapsto \int_{A \times B} c(a, b) \pi(dadb) \text{ subject to } \pi \in P(\mu, \nu) \quad (\text{MK})$$

where $P(\mu, \nu)$ is the set of all $\pi \in \mathcal{P}_{AB}$ with prescribed marginals $\pi_A = \mu$ on $A$ and $\pi_B = \nu$ on $B$. Note that $c$ is measurable since it is lower semicontinuous and the integral

Key words and phrases. Convex optimization, saddle-point, conjugate duality, optimal transport.
\[ \int_{A \times B} c \, d\pi \in [0, \infty) \] is well-defined since \( c \geq 0 \).

For a general account on this active field of research, see the books of S. Rachev and L. Rüschendorf [15] and C. Villani [18, 19].

The subset \( \{ c = \infty \} \) of \( A \times B \) is a set of forbidden transitions. Optimal transport on the Wiener space [11] and on configuration spaces [8, 9] provide natural infinite dimensional settings where \( c \) takes infinite values.

Let us denote \( C_A, C_B \) and \( C_{AB} \) the spaces of all continuous bounded functions on \( A, B \) and \( A \times B \). The Kantorovich maximization problem:

\[
\begin{cases}
\text{maximize} & \int_A f \, d\mu + \int_B g \, d\nu \quad \text{for all } f, g \text{ such that} \\
& f \in C_A, g \in C_B \text{ and } f \oplus g \leq c
\end{cases}
\]

(K)

is the basic dual problem of \( (MK) \). Here and below, we denote the uninteresting case where \( \mu \otimes \nu \) is nonempty; this will be found again in Theorem 3.2. Definition 1.2-3 throws away the \( \mu \otimes \nu \)-almost everywhere. This leads naturally to the following notion.

\[ \inf (MK) = \sup (K) \in [0, \infty) \]

(1.1)

which is called the Kantorovich dual equality. For a proof of this well known result, see [19, Thm 5.10] for instance.

**Definitions 1.2 (Plans).**

1. Any probability measure in \( P(\mu, \nu) \) is called a transport plan, or shorter: a plan.
2. One says that \( \pi \in P(\mu, \nu) \) is a finite plan if \( \int_{A \times B} c \, d\pi < \infty \). The set of all finite plans is denoted by \( P(\mu, \nu, c) \).
3. One says that \( \pi \) is an optimal plan if it is a finite plan and it minimizes \( \gamma \mapsto \int_{A \times B} c \, d\gamma \) on \( P(\mu, \nu) \).

It is well-known that there exists at least an optimal plan if and only if \( P(\mu, \nu, c) \) is nonempty; this will be found again in Theorem 3.2. Definition 1.2-3 throws away the uninteresting case where \( \int_{A \times B} c \, d\pi = \infty \) for all \( \pi \in P(\mu, \nu) \).

Since it is a convex but not a strictly convex problem, infinitely many optimal plans may exist.

Recently, M. Beiglböck, M. Goldstern, G. Maresh, W. Schachermayer and J. Teichman [17, 2, 4] have improved previous optimality criteria in several directions. Before stating some of their results, let us introduce the notion of strongly \( c \)-cyclically monotone plan.

Clearly, there is no reason for the dual equality (1.1) to be attained at continuous functions \( f \) and \( g \). Suppose instead that there exist two \( [-\infty, \infty) \)-valued integrable functions \( f \in \mathcal{L}^1(\mu) \) and \( g \in \mathcal{L}^1(\nu) \) such that \( f \oplus g \leq c \) everywhere and \( \sup \{ \int_A u \, d\mu + \int_B v \, d\nu ; u \in \mathcal{L}^1(\mu), v \in \mathcal{L}^1(\nu) \} = \int_A f \, d\mu + \int_B g \, d\nu. \) Let \( \pi \) be an optimal plan. We have

\[
\sup (K) \leq \sup_{u \in \mathcal{L}^1(\mu), v \in \mathcal{L}^1(\nu)} \int_A u \, d\mu + \int_B v \, d\nu = \int f \oplus g \, d\pi \leq \int c \, d\pi = \inf (MK)
\]

and by (1.1), this is a series of equalities. In particular, the couple \((f, g)\) is an integrable dual optimizer, \( \int (c - f \oplus g) \, d\pi = 0 \) and since \( c - f \oplus g \geq 0 \), we see that \( c = f \oplus g \), \( \pi \)-almost everywhere. This leads naturally to the following notion.

**Definition 1.3 (Strongly \( c \)-cyclically monotone plan, [17]).** A transport plan \( \pi \in P(\mu, \nu) \) is called strongly \( c \)-cyclically monotone if there exist \( [-\infty, \infty) \)-valued measurable functions \( f \) on \( A \) and \( g \) on \( B \) such that

\[
\begin{cases}
 f \oplus g \leq c \quad \text{everywhere} \\
 f \oplus g = c \quad \pi \text{-almost everywhere}
\end{cases}
\]

(1.4)
In the whole paper, measurable functions and sets are intended to be Borel measurable. Note that it is not required in this definition that \( f \) and \( g \) are integrable. In fact, one can find examples where there is an optimal plan but no integrable dual optimizer, see [4, Example 4.5]. Without integrability, one cannot write \( \int_A f \, d\mu + \int_B g \, d\nu \) anymore. Nevertheless, the following result allows us to extend the notion of dual optimizer to measurable functions \((f, g)\) as in Definition 1.3.

**Lemma 1.5.** [4, Lemma 1.1] Let \( c : A \times B \to [0, \infty] \) be measurable, \( f \) and \( g \) be \([−\infty, \infty)\)-valued measurable functions on \( A \) and \( B \) respectively such that \( f \oplus g \leq c \) everywhere. Then, for any \( \pi, \tilde{\pi} \in P(\mu, \nu, c) \),

\[
\int_{A \times B} f \oplus g \, d\pi = \int_{A \times B} f \oplus g \, d\tilde{\pi} \in [−\infty, \infty).
\]

With this lemma in hand, we are allowed to denote

\[
\int_{A \times B} f \oplus g \, d(\mu, \nu, c) := \int_{A \times B} f \oplus g \, d\pi, \quad \pi \in P(\mu, \nu, c)
\]

this common value. A natural extension of the dual problem (K) is

\[
\begin{cases}
\text{maximize} & \int_{A \times B} f \oplus g \, d(\mu, \nu, c) \text{ for all } f \in [−\infty, \infty]^A, g \in [−\infty, \infty]^B \\
& f, g \text{ measurable such that } f \oplus g \leq c \text{ everywhere.}
\end{cases}
\]

(A)\( \tilde{K} \)

Of course, \( \sup (K) \leq \sup (\tilde{K}) \leq \inf (M_K) \) so that (1.1) implies

\[
\sup (\tilde{K}) = \inf (M_K).
\]

A couple of functions \((f, g)\) as in Definition 1.3 is clearly an optimizer of \((\tilde{K})\). We call it a measurable dual optimizer.

Some usual optimality criteria are expressed in terms of cyclical \(c\)-monotonicity.

**Definition 1.8** (c-cyclically monotone plan). A subset \( \Gamma \subset A \times B \) is said to be c-cyclically monotone if for any integer \( n \geq 1 \) and any family \((a_1, b_1), \ldots, (a_n, b_n)\) of points in \( \Gamma \),

\[
\sum_{i=1}^n c(a_i, b_i) \leq \sum_{i=1}^n c(a_i, b_{i+1}) \quad \text{with the convention } b_{n+1} = b_1.
\]

A probability measure \( \pi \in P_{AB} \) is said to be c-cyclically monotone if it is concentrated on a measurable c-cyclically monotone set \( \Gamma \), i.e. \( \pi(\Gamma) = 1 \).

This notion goes back to the seminal paper [16] by L. Rüschendorf where the standard cyclical monotonicity of convex functions introduced by Rockafellar has been extended in view of solving the Monge-Kantorovich problem.

One easily shows that a strongly c-cyclically monotone plan is c-cyclically monotone.

The main results of [17, 2, 4] are collected in the next two theorems.

**Theorem 1.9** ([2, 4]). Let \( c \) be a measurable nonnegative function such that

\[
\mu \otimes \nu(\{c < \infty\}) = 1.
\]

If there exists some \( \pi^o \in P(\mu, \nu) \) such that \( \int_{A \times B} c \, d\pi^o < \infty \), then (1.7) holds true and for any \( \pi \in P(\mu, \nu) \), the following three statements are equivalent:

(i) \( \pi \) is an optimal plan;
(ii) \( \pi \) is c-cyclically monotone;
(iii) \( \pi \) is strongly c-cyclically monotone.
This result is valid under a very weak regularity condition on \( c \) which is only assumed to be Borel measurable. It was first proved in [17] under the assumption that \( c \) is a lower semicontinuous nonnegative finitely-valued function. However, condition (1.10) is close to the assumption that \( c \) is finitely valued.

The next result is concerned with cost functions \( c \) which may take infinite values.

**Theorem 1.11** ([1, 17, 2]). Let \( c \) be a lower semicontinuous \([0, \infty]\)-valued function.

(a) Any optimal plan is \( c \)-cyclically monotone.

(b) If there exists some \( \pi^o \in P(\mu, \nu) \) such that \( \int_{A \times B} c \, d\pi^o < \infty \), then any strongly \( c \)-cyclically monotone plan in \( P(\mu, \nu) \) is an optimal plan.

Let \( c \) be a measurable \([0, \infty]\)-valued function.

(c) Every finite \( c \)-cyclically monotone transport plan is optimal if there exist a closed set \( F \) and a \( \mu \otimes \nu \)-null set \( N \) such that \( \{c = \infty\} = F \cup N \).

Statement (a) is proved in L. Ambrosio and A. Pratelli’s lecture notes [1] and (b) is taken from [17]. Statement (c) is proved in [2], it extends recent results of A. Pratelli [14].

**Counterexamples 1.12.** Otherwise stated, \( c \) is assumed to be lower semicontinuous.

(1) \( c \) is real valued.

(a) [2, Example 1.3] \( c \) is not lower semicontinuous and no optimal plan exists.

(b) [4, Example 4.5] \( c \) is the squared distance and no integrable dual optimizers exist.

(2) \( c \) takes infinite values on a non-null set.

(a) [4, Example 4.1] \( c \) is not lower semicontinuous and the weak Kantorovich dual equality (1.7) fails to hold: We have sup (\( \tilde{K} \)) < inf (\( MK \)).

(b) [1, Example 3.5] A \( c \)-cyclically monotone plan which is not optimal.

(c) [17, Example 1] A \( c \)-cyclically monotone plan which is not strongly \( c \)-cyclically monotone.

(d) [2, Example 5.1] An optimal plan which is not strongly \( c \)-cyclically monotone.

(e) [4, Example 4.2] An optimal plan which is not strongly \( c \)-cyclically monotone with \( c \) continuous.

It appears that Theorem 1.9 is the best possible result under the assumption (1.10) but that its extension to the general case where \( c \) takes infinite values on a non-null set is still open. The Counterexample 2-b tells us that one must drop the notion of \( c \)-cyclically monotone plan and with the Counterexamples 2-d and 2-e, one sees that even the notion of strongly \( c \)-cyclically monotone plan is not enough to characterize optimality.

Because of the dual gap when \( c \) is not lower semicontinuous (Counterexample 2-a), it is reasonable to assume that \( c \) is lower semicontinuous in the general case. This will be assumed from now on.

**The aim of this paper.** This paper is aimed at implementing the saddle-point method for solving (MK) in the general case where \( c \) might take infinite values, without appealing to \( c \)-conjugates, see [18, 19]. After all, (MK) is a convex minimization problem and one may wonder what the standard approach based on convex duality could yield. It appears that an extended version of the saddle-point is necessary to investigate (MK) without imposing strong qualifications of the constraints such as the standard requirement: \( \int_A c_A \, d\mu + \int_B c_B \, d\nu < \infty \) where \( c \leq c_A \oplus c_B \), see [18, 19]. The present paper relies on an extension of the standard saddle-point method which has been developed in [12].
- A new proof of the Kantorovich dual equality (1.1) is given in Theorem 3.2 providing at the same time an improved result about the behavior of the minimizing sequences of $(\mathcal{MK})$.
- An abstract characterization of the optimal plans is given in Theorem 4.6. It expresses a saddle-point property and extends the notion of strong $c$-cyclical monotonicity.
- It leads easily to a sufficient condition of optimality in Theorem 1.13 below which is an improvement of Theorem 1.11-b. Its proof is given in Section 5.
- Finding good necessary conditions for optimal plans with a genuinely $[0, \infty]$-valued cost function $c$ is still an open problem. Theorem 1.15 below, which is a corollary of Theorem 4.6, goes one step in this direction. Its proof is given in Section 6.

One says that $f$ is $\mu$-measurable if there exists a measurable set $N$ such that $\mu(N) = 0$ and $1_N f$ is a measurable function. A property holds $P(\mu, \nu, c)$-almost everywhere if it holds true outside a measurable set $N$ such that $\gamma(N) = 0$, for all $\gamma \in P(\mu, \nu, c)$. With these definitions in hand, we can state our sufficient condition of optimality.

**Theorem 1.13.** Let $\pi \in P(\mu, \nu, c)$ be any finite plan. If there exist a $\mu$-measurable function $f$ on $A$ and a $\nu$-measurable function $g$ on $B$ which satisfy
\[
\begin{cases}
 f \oplus g \leq c & P(\mu, \nu, c)\text{-almost everywhere} \\
 f \oplus g = c & \pi\text{-almost everywhere},
\end{cases}
\]
then $\pi$ is optimal.

The Counterexamples 1.12-(d,e) are optimal plans which are not strongly $c$-cyclically monotone but they both satisfy the weaker property (1.14). See Subsection 5.3 for more details.

The following result is our necessary condition of optimality.

**Theorem 1.15.** Take any optimal plan $\pi$, $\epsilon > 0$ and $p$ any probability measure on $A \times B$ such that $\int_{A \times B} c \, dp < \infty$. Then, there exist functions $\varphi \in L_1(\pi + p)$, $u$ and $v$ bounded continuous on $A$ and $B$ respectively and a measurable subset $D \subset A \times B$ such that
\[
\begin{align*}
(1) & \quad \varphi = c, \quad \pi\text{-almost everywhere on } A \times B \setminus D; \\
(2) & \quad \int_D (1 + c) \, d\pi \leq \epsilon; \\
(3) & \quad -c/\epsilon \leq \varphi \leq c, \quad (\pi + p)\text{-almost everywhere}; \\
(4) & \quad -c/\epsilon \leq u \oplus v \leq c, \quad \text{everywhere}; \\
(5) & \quad \|\varphi - u \oplus v\|_{L_1(\pi + p)} \leq \epsilon.
\end{align*}
\]

An important thing to notice in this result is the appearance of the probability measure $p$ in items (3) and (5). One can read (3-5) as an approximation of $f \oplus g \leq c$, $(\pi + p)$-almost everywhere. Since it is required that $\int_{A \times B} c \, dp < \infty$, one can choose $p$ in $P(\mu, \nu, c)$, and the properties (1-5) of this theorem are an approximation of (1.14) where $P(\mu, \nu, c)$-a.e. is replaced by $(\pi + p)$-a.e.

In [3], M. Beiglböck, W. Schachermayer and the author of the present paper investigate the same problem with a different approach which is still based on a saddle point method. A characterization of optimal plans which is more explicit than Theorem 4.6 is obtained under some restrictive assumptions. In particular, the problem of considering simultaneously all the measures $p \in P(\mu, \nu, c)$ in Theorem 1.15 is handled by means of a projective limit argument.

**Notation.** Let $X$ and $Y$ be topological vector spaces and $f : X \to [-\infty, +\infty]$ be an extended-real valued function.
- The algebraic dual space of $X$ is $X^*$, the topological dual space of $X$ is $X'$. 

- The topology of $X$ weakened by $Y$ is $\sigma(X,Y)$ and one writes $\langle X, Y \rangle$ to specify that $X$ and $Y$ are in separating duality.
- The convex conjugate of $f$ with respect to $\langle X, Y \rangle$ is $f^*(y) = \sup_{x \in X} \{ \langle y, x \rangle - f(x) \} \in [-\infty, +\infty]$, $y \in Y$.
- The subdifferential of $f$ at $x$ with respect to $\langle X, Y \rangle$ is $\partial_y f(x) = \{ y \in Y ; f(x + \xi) \geq f(x) + \langle y, \xi \rangle, \forall \xi \in X \}$. If no confusion occurs, one writes $\partial f(x)$.
- The effective domain of $f$ is $\text{dom} f = \{ x \in X; f(x) < \infty \}$.
- One denotes $\text{icordom} f$ the intrinsic core of the effective domain of $f$. Recall that the intrinsic core of a subset $A$ of a vector space is $\text{icor} A = \{ x \in A; \forall x' \in \text{aff} A, \exists t > 0, [x, x + t(x'-x)] \subset A \}$ where $\text{aff} A$ is the affine space spanned by $A$.
- The domain of $\partial f$ is $\text{dom} \partial f = \{ x \in X; \partial f(x) \neq \emptyset \}$.
- The indicator function of a subset $A$ of $X$ is defined by
  \[ \iota_A(x) = \begin{cases} 0, & \text{if } x \in A \\ +\infty, & \text{otherwise} \end{cases}, \quad x \in X. \]
- The support function of $A \subset X$ is $\iota_A^*(y) = \sup_{x \in A} \langle x, y \rangle$, $y \in Y$.
- The Dirac measure at $a$ is denoted $\delta_a$.

Acknowledgements. The author thanks Stefano Bianchini for very useful comments.

2. The abstract convex minimization problem

The Monge-Kantorovich problem is a particular instance of an abstract convex minimization problem which is solved in [12] by means of an extension of the saddle-point method. This extension allows to remove standard topological restrictions on the constraint sets (the so-called constraint qualifications) at the price of solving an arising new problem. Namely, one has to compute a lower semicontinuous convex extension of the convex conjugate of the objective function. This may be a rather difficult task in some situations, but it is immediate in the case of the Monge-Kantorovich problem.

Let us recall the main results of [12].

The minimization problem. Let $\mathcal{U}_o$, $\mathcal{Y}_o$ be two vector spaces,
\[ \Phi_o : \mathcal{U}_o \rightarrow [0, \infty] \]

an extended-nonnegative function on $\mathcal{U}_o$, and
\[ T^*_o : \mathcal{Y}_o \rightarrow \mathcal{U}_o \]
a linear mapping from $\mathcal{Y}_o$ to $\mathcal{U}_o$. Throughout this section, it is assumed that
\[
\begin{align*}
(H_\Phi) & 1- \Phi_o : \mathcal{U}_o \rightarrow [0, +\infty] \text{ is convex and } \Phi_o(0) = 0 \\
& 2- \forall u \in \mathcal{U}_o, \exists \alpha > 0, \Phi_o(\alpha u) < \infty \\
& 3- \forall u \in \mathcal{U}_o, u \neq 0, \exists t \in \mathbb{R}, \Phi_o(tu) > 0 \\
(H_T) & 1- T^*_o(\mathcal{Y}_o) \subset \mathcal{U}_o \\
& 2- \ker T^*_o = \{0\}
\end{align*}
\]

Let $\mathcal{L}_o$ and $\mathcal{X}_o$ be the algebraic dual vector spaces of $\mathcal{U}_o$ and $\mathcal{Y}_o$. The convex conjugate of $\Phi_o$ with respect to the dual pairing $\langle \mathcal{U}_o, \mathcal{L}_o \rangle$ is
\[ \Phi_o^*(\ell) = \sup_{u \in \mathcal{L}_o} \{ \langle u, \ell \rangle - \Phi_o(u) \} \in [0, \infty], \quad \ell \in \mathcal{L}_o \]
and the adjoint of $T^*_o$ is $T_o : \mathcal{L}_o \to \mathcal{X}_o$ defined for all $\ell \in \mathcal{L}_o$ by $\langle y, T_o \ell \rangle_{\mathcal{Y}_o, \mathcal{X}_o} = \langle T^*_o y, \ell \rangle_{\mathcal{U}_o, \mathcal{L}_o}$. We obtain the diagram

$$
\begin{array}{ccc}
\langle \mathcal{U}_o, \mathcal{L}_o \rangle & \xrightarrow{T^*_o} & \langle \mathcal{Y}_o, \mathcal{X}_o \rangle \\
T_o & \downarrow & T_o \\
\langle \mathcal{U}_o, \mathcal{L}_o \rangle & \xrightarrow{T^*_o} & \langle \mathcal{Y}_o, \mathcal{X}_o \rangle
\end{array}
$$

(Diagram 0)

For each $x \in \mathcal{X}_o$, the optimization problem to be considered is

$$\minimize \Phi^*_o(\ell) \quad \text{subject to} \quad T_o \ell = x, \quad \ell \in \mathcal{L}_o \quad (P^*_o)$$

**A dual problem.** Let us define

$$
\begin{align*}
\Lambda_o(y) & := \Phi_o(T^*_o y), \quad y \in \mathcal{Y}_o \\
|u|_\Phi & := \inf \left\{ a > 0; \max \left( \Phi_o(-u/a), \Phi_o(u/a) \right) \leq 1 \right\}, \quad u \in \mathcal{U}_o \\
|y|_\Lambda & := \inf \left\{ a > 0; \max \left( \Lambda_o(-y/a), \Lambda_o(y/a) \right) \leq 1 \right\}, \quad y \in \mathcal{Y}_o
\end{align*}
$$

Under our assumptions, $| \cdot |_\Phi$ and $| \cdot |_\Lambda$ are norms. One introduces

- $\mathcal{U}$ and $\mathcal{Y}$ the completions of $(\mathcal{U}_o, | \cdot |_\Phi)$ and $(\mathcal{Y}_o, | \cdot |_\Lambda)$;
- The *topological* dual spaces of $\mathcal{U}$ and $\mathcal{Y}$ are $\mathcal{U}' = \mathcal{L}$ and $\mathcal{Y}' = \mathcal{X}$;
- The *algebraic* dual spaces of $\mathcal{L}$ and $\mathcal{X}$ are denoted by $\mathcal{L}^*$ and $\mathcal{X}^*$;
- $T$ is the restriction of $T_o$ to $\mathcal{L} \subset \mathcal{L}_o$;
- $\Phi^*$ is the restriction of $\Phi^*_o$ to $\mathcal{L} \subset \mathcal{L}_o$.

It is proved in [12] that $T \mathcal{L} \subset \mathcal{X}$. This allows one to define the algebraic adjoint $T^* : \mathcal{L}^* \to \mathcal{X}^*$. We have the following diagram

$$
\begin{array}{ccc}
\langle \mathcal{L}, \mathcal{L}^* \rangle & \xrightarrow{T} & \langle \mathcal{X}, \mathcal{X}^* \rangle \\
\uparrow & & \uparrow T^* \\
\langle \mathcal{L}, \mathcal{L}^* \rangle & \xrightarrow{T} & \langle \mathcal{X}, \mathcal{X}^* \rangle
\end{array}
$$

(Diagram 1)

Also consider

$$
\begin{align*}
\overline{\Phi}(\zeta) & := \sup_{\ell \in \mathcal{L}} \{ \langle \zeta, \ell \rangle - \Phi^*(\ell) \}, \quad \zeta \in \mathcal{L}^* \\
\overline{\Lambda}(\omega) & := \sup_{\ell \in \mathcal{L}} \{ \langle T^* \omega, \ell \rangle \}, \quad \omega \in \mathcal{X}^*. \quad (2.1)
\end{align*}
$$

The maximization problem

$$\maximize \langle \omega, x \rangle - \overline{\Lambda}(\omega), \quad \omega \in \mathcal{X}^* \quad (\overline{D}^*)$$

is the dual problem associated with

$$\minimize \Phi^*(\ell) \quad \text{subject to} \quad T \ell = x, \quad \ell \in \mathcal{L} \quad (P^x)$$

with respect to the usual Fenchel perturbation.

**Statements of the abstract results.** Let us introduce

$$\Lambda^*(x) := \sup_{y \in \mathcal{Y}_o} \{ \langle y, x \rangle - \Lambda_o(y) \}, \quad x \in \mathcal{X}$$

the convex conjugate of $\Lambda_o + \iota_{\mathcal{Y}_o}$ with respect to the dual pairing $\langle \mathcal{Y}, \mathcal{X} \rangle$.

**Theorem 2.2** (Primal attainment and dual equality, [12]). Assume that $(H_\Phi)$ and $(H_T)$ hold.
(a) For all \( x \in \mathcal{X} \), we have the dual equality
\[
\inf\{\Phi^*(\ell); \ell \in \mathcal{L}, T\ell = x\} = \inf(P^*_o) = \inf(P^x) = \Lambda^*(x) \in [0, \infty].
\] (2.3)
Moreover, \( \Lambda^* \) is \( \sigma(\mathcal{X}, \mathcal{Y}) \)-inf-compact.

(b) If \( x \notin \mathcal{X} \), \( (P^*_o) \) admits no solution. Otherwise, \( P^*_o \) and \( P^x \) admit the same (possibly empty) set of solutions.

(c) If in addition \( x \in \text{dom } \Lambda^* \), then \( P^x \) (or equivalently \( P^*_o \)) is attained in \( \mathcal{L} \). Moreover, any minimizing sequence for \( P^x \) has \( \sigma(\mathcal{L}, \mathcal{U}) \)-cluster points and every such cluster point solves \( P^x \).

Denote the “algebraic” subdifferentials
\[
\partial_{\mathcal{L}} \Phi(\zeta_o) = \{ \ell \in \mathcal{L}; \Phi(\zeta_o + \zeta) \geq \Phi(\zeta_o) + \langle \zeta, \ell \rangle, \forall \zeta \in \mathcal{L}^* \}, \quad \zeta_o \in \mathcal{L}^*
\]
\[
\partial_{\mathcal{X}^*} \Lambda^*(x_o) = \{ \omega \in \mathcal{X}^*; \Lambda^*(x_o + x) \geq \Lambda^*(x_o) + \langle \omega, x \rangle, \forall x \in \mathcal{X} \}, \quad x_o \in \mathcal{X}
\]
and define
\[
\text{dom} \partial \Lambda^* = \{ x \in \mathcal{X}; \partial_{\mathcal{X}^*} \Lambda^*(x) \neq \emptyset \}
\]
the subset of the constraint specifiers \( x \in \mathcal{X} \) such that \( \partial_{\mathcal{X}^*} \Lambda^*(x) \) is not empty.

**Theorem 2.4** (Dual attainment and representation, [12]). Let us assume that \((H_\Phi)\) and \((H_T)\) hold.

1. For any \( \ell \in \mathcal{L} \) and \( \omega \in \mathcal{X}^* \),
\[
\begin{cases}
T\ell = x \\
\ell \in \partial_{\mathcal{L}} \Phi(T^*\omega)
\end{cases}
\]

is equivalent to
\[
\ell \text{ is a solution to } P^x, \quad \omega \text{ is a solution to } D^x \text{ and the dual equality } \inf(P^x) = \Lambda^*(x) \text{ holds.}
\]

2. Suppose that in addition the constraint qualification
\[
x \in \text{dom} \partial \Lambda^*,
\]
(2.6)
is satisfied. Then, the primal problem \( P^x \) is attained in \( \mathcal{L} \), the dual problem \( D^x \) is attained in \( \mathcal{X}^* \) and every couple of solutions \((\ell, \omega)\) to \( P^x \) and \( D^x \) satisfies (2.5).

By the geometric version of Hahn-Banach theorem, \( \text{icordom } \Lambda^* \) : the intrinsic core of \( \text{dom } \Lambda^* \), is included in \( \text{dom} \partial \Lambda^* \). But, as will be seen at Remark 4.9 below, the Monge-Kantorovich problem provides us with a situation where \( \text{icordom } \Lambda^* \) is empty. This is one of the main difficulties to be overcome when applying the saddle-point method to solve \((MK)\).

It is a well-known result of convex conjugacy that the representation formula
\[
\ell \in \partial_{\mathcal{L}} \Phi(T^*\omega)
\]
(2.7)
is equivalent to
\[
T^*\omega \in \partial_{\mathcal{L}} \Phi^*(\ell)
\]
and also equivalent to Fenchel’s identity
\[
\Phi^*(\ell) + \Phi(T^*\omega) = \langle \omega, T\ell \rangle.
\]
(2.8)

**Proposition 2.9** ([12]). Assume that \((H_\Phi)\) and \((H_T)\) hold. Any solution \( \omega \in \mathcal{X}^* \) of \( D^x \) shares the following properties
(a) $\omega$ is in the $\sigma(\mathcal{X}^*, \mathcal{X})$-closure of $\text{dom } \Lambda$;
(b) $T^*\omega$ is in the $\sigma(\mathcal{L}^*, \mathcal{L})$-closure of $T^*(\text{dom } \Lambda)$.

If in addition the level sets of $\Phi_o$ are $|\cdot|_\Phi$-bounded, then

(a') $\omega$ is in $\mathcal{Y}''$. More precisely, it is in the $\sigma(\mathcal{Y}''', \mathcal{X})$-closure of $\text{dom } \Lambda$;
(b') $T^*\omega$ is in $\mathcal{U}''$. More precisely, it is in the $\sigma(\mathcal{U}''', \mathcal{L})$-closure of $T^*(\text{dom } \Lambda)$.

where $\mathcal{Y}''$ and $\mathcal{U}''$ are the topological bidual spaces of $(\mathcal{U}, |\cdot|_\Phi)$ and $(\mathcal{Y}, |\cdot|_\Lambda)$.

3. Kantorovich dual equality and existence of optimal plans

We apply the results of Section 2 to the Monge-Kantorovich problem (MK).

3.1. Statement of the results. The set of all probability measures $\pi$ on $A \times B$ such that $\int_{A \times B} c \, d\pi < \infty$ is denoted $\mathcal{P}_c$. Hence, $P(\mu, \nu, c) = \mathcal{P}_c \cap P(\mu, \nu)$. It is immediate to see that

$$\sup (K) \leq \sup (\tilde{K}) \leq \inf (MK) \quad (3.1)$$

where for the last inequality, we state $\inf \emptyset = +\infty$ as usual.

In the next theorem, $\mathcal{P}_c$ will be endowed with the weak topology $\sigma(\mathcal{P}_c, \mathcal{C}_c)$ where $\mathcal{C}_c$ is the space of all continuous functions $u$ on $A \times B$ such that

$$\lim_{t \to \infty} \sup \{|u(x)|/(1 + c(x)); x \in A \times B, |u(x)| \geq t\} = 0$$

with the convention that $\sup \emptyset = 0$ which implies that the space $\mathcal{C}_{AB}$ of bounded continuous functions on $A \times B$ satisfies $\mathcal{C}_{AB} \subset \mathcal{C}_c$.

**Theorem 3.2** (Dual equality and primal attainment).

(1) The dual equality for (MK) is

$$\inf (MK) = \sup (K) = \sup (\tilde{K}) \in [0, \infty]. \quad (3.3)$$

(2) Assume that there exists some $\pi^o$ in $P(\mu, \nu)$ such that $\int_{A \times B} c \, d\pi^o < \infty$. Then:

(a) There is at least one optimal plan;
(b) Any minimizing sequence is relatively compact for the topology $\sigma(\mathcal{P}_c, \mathcal{C}_c)$ and all its cluster points are optimal plans.

**Proof.** It directly follows from Theorem 2.2 with Proposition 3.8-(3) and Proposition 3.11 which are stated and proved below. About statement (1), note that the dual equality (2.3) is $\inf (MK) = \sup (K)$ and conclude with (3.1). \qed

Except for the appearance of the dual problem ($\tilde{K}$) and for the statement (2-b) with the topology $\sigma(\mathcal{P}_c, \mathcal{C}_c)$, this result is well-known. The dual equality (3.3) is the Kantorovich dual equality. The proof of Theorem 3.2 will be an opportunity to make precise the abstract material $\Phi_o, U_o, T_o$ and so on in terms of the Monge-Kantorovich problem.

3.2. The spaces and functions. Let us particularize the spaces and functions of Section 2 which are necessary for solving the Monge-Kantorovich problem.
Description of $\mathcal{U}_o$, $\mathcal{L}_o$, $\Phi_o$ and $\Phi_o^*$.

Define

$$ S := \{(a, b) \in A \times B; c(a, b) < \infty\} $$

the effective domain of $c$ and consider the equivalence relation on $C_{AB}$ defined for any $u, v$ in $C_{AB}$ by

$$ u \sim v \Longleftrightarrow u|_S = v|_S, $$

which means that $u$ and $v$ match on $S$. Take

$$ \mathcal{U}_o := C_{AB} / \sim $$

the set of all equivalence classes and

$$ \Phi_o(u) := \chi_\Gamma(u) = \begin{cases} 0, & \text{if } u \leq c + \infty, \\ +\infty, & \text{otherwise} \end{cases}, \quad u \in \mathcal{U}_o $$

the convex indicator function of

$$ \Gamma = \{u \in \mathcal{U}_o; u \leq c\}. $$

Assumption $(H_{\Phi_1})$ is obviously satisfied and it is easy to see that $(H_{\Phi_3})$ also holds. Note that, without factorizing by the equivalence relation in the definition of $\mathcal{U}_o$, $(H_{\Phi_3})$ would fail if $c$ is infinite on some nonempty open set. For $(H_{\Phi_2})$ to be satisfied, assume that $c \geq 1$.

Doing this, one doesn’t loose any generality since changing $c$ into $c + 1$ raises $\inf(MK)$ by +1 without changing the minimizers.

The algebraic dual space $\mathcal{L}_o = \mathcal{U}_o^*$ of $\mathcal{U}_o$ is identified as a subset of $C_{AB}^*$ as follows. Any $\ell \in C_{AB}^*$ is in $\mathcal{L}_o$ if and only if for all $u, v \in C_{AB}$ such that $u|_S = v|_S$, we have $\ell(u) = \ell(v)$. One shows at Proposition 3.5 below that any $\ell \in C_{AB}^*$ which is in $\mathcal{L}_o$ has its support included in the closure $\text{cl}S$ of $S$ in the sense of the following

**Definition 3.4.** For any linear form $\ell$ on the space of all (possibly unbounded) continuous functions on $A \times B$, we define the support of $\ell$ as the subset of all $(a, b) \in A \times B$ such that for any open neighborhood $G$ of $(a, b)$, there exists some function $u$ in $C_{AB}$ satisfying $\{u \neq 0\} \subset G$ and $\langle u, \ell \rangle \neq 0$. It is denoted by $\text{supp} \ell$.

**Proposition 3.5.** For any $\ell \in \mathcal{L}_o$, we have $\text{supp} \ell \subset \text{cl}S$.

**Proof.** As $\ell \in \mathcal{L}_o$, for all $u \in C_{AB}$ such that $u|_S = 0$, we have $\langle u, \ell \rangle = 0$. Take $x \notin \text{cl}S$. There exists an open neighborhood $G$ of $x$ such that $G \cap S = \emptyset$. For all $u \in C_{AB}$ such that $\{u \neq 0\} \subset G$, we have $u|_S = 0$ so that $\langle u, \ell \rangle = 0$. This proves that $x \notin \text{supp} \ell$. \hfill $\Box$

Denote $C|_S$ the space of the restrictions $u|_S$ of all the functions $u$ in $C_{AB}$.

**Remark 3.6.** Beware, $C|_S$ is smaller than the space $C_S$ of all bounded and continuous functions on $S$. It consists of the functions in $C_S$ which admit a continuous and bounded extension to $A \times B$.

Identifying

$$ \mathcal{U}_o \cong C|_S, $$

one sees with Proposition 3.5 that for all $\ell \in \mathcal{L}_o$,

$$ \Phi_o^*(\ell) := \sup \{\langle u, \ell \rangle; u \in C|_S, u \leq c\}. $$
Description of $Y_o$, $X_o$, $T_o^*$ and $T_o$. Consider

$$Y_o := (C_A \times C_B) / \sim$$

where $C_A$, $C_B$ are the spaces of bounded continuous functions on $A$, $B$ and $\sim$ is a new equivalence relation on $C_A \times C_B$ defined for all $f, f' \in C_A$, $g, g' \in C_B$ by

$$(f, g) \sim (f', g') \iff f \oplus g \sim f' \oplus g' \iff f \oplus g \in S = f' \oplus g_S.'$$

The algebraic dual space $X_o = Y_o^*$ of $Y_o$ is identified as a subset of $C_A^* \times C_B^*$ as follows. Any $(k_1, k_2) \in C_A^* \times C_B^*$ is in $X_o$ if and only if for all $f, f' \in C_A$, $g, g' \in C_B$ such that $f \oplus g \in S = f' \oplus g_S$, we have $(f, k_1) + (g, k_2) = (f', k_1) + (g', k_2)$.

It is immediate to see that the operator $T_o^*$ defined by

$$T_o^*(f, g) := f \oplus g_S, \quad (f, g) \in Y_o$$

satisfies the assumptions $(H_T)$. In particular, one sees that $T_o^*(Y_o) \subset C_L$.

Define the $A$ and $B$-marginal projections $\ell_A \in C_A^*$ and $\ell_B \in C_B^*$ of any $\ell \in C_{AB}^*$ by

$$\langle f, \ell_A \rangle := \langle f \oplus \ell, 1 \rangle \quad \text{and} \quad \langle g, \ell_B \rangle := \langle 1 \oplus g, \ell \rangle$$

for all $f \in C_A$ and all $g \in C_B$. Since for all $(f, g) \in Y_o$, $(T_o^*(f, g), \ell)_{C_L} = \langle f, \ell_A \rangle + \langle g, \ell_B \rangle = \langle (f, g), (\ell, \ell) \rangle$, one obtains that for all $\ell \in C_A \times C_B^*$

$$T_o(\ell) = (\ell_A, \ell_B) \in X_o \subset C_A^* \times C_B^*.$$

Description of $U$ and $Y$. For each $u \in C_L$, $\Phi_o(u) := \max(\Phi_o(u), \Phi_o(-u)) = \iota_{\{u|_S \leq 1\}}$. Hence, $|u|_\Phi$ is the norm

$$|u|_c := \sup_{S^*} |u|/c, \quad u \in C_L$$

Recall that it is assumed that $c \geq 1$. Let us denote the Banach space

$$U := U_c$$

which is the completion of $C_L$ with respect to the norm $\| \cdot \|_c$.

**Proposition 3.8.**

(1) $U_c$ is a space of functions on $S$ which are continuous in restriction to each level set $\{c \leq \alpha\}$, $\alpha \geq 1$. In particular, any $u \in U_c$ is a measurable function.

(2) Even if $c$ is finite everywhere, $U_c$ may contain functions which are not continuous.

(3) $C_c \subset U_c$.

**Proof.** Proof of (1). Let $(u_n)_{n \geq 1}$ be a $\| \cdot \|_c$-Cauchy sequence in $C_L$. For all $x \in S$, $\lim_{n \to \infty} u_n(x) := \mathbb{u}(x)$ exists since $(u_n(x))_{n \geq 1}$ is a Cauchy sequence in $\mathbb{R}$. For each $\epsilon > 0$, there are large enough $n, m$ such that $\sup_{x \in S} |u_n(x) - u_m(x)|/c(x) \leq \epsilon$ for all $x \in S$. Letting $m$ tend to infinity leads us to $|u_n(x) - u_m(x)|/c(x) \leq \epsilon$ for all $x \in S$, which gives us

$$\lim_{n \to \infty} \|u_n - u\|_c = 0$$

where the definition $\|v\|_c := \sup_S |v|/c$ still holds for any function $v$ on $S$. As for any $x, y \in S$,

$$\frac{u(x) - u(y)}{c(x) + c(y)} \leq 2\|u - u\|_c + \frac{u_n(x) - u_n(y)}{c(x) + c(y)} \leq 2\|u - u\|_c + |u_n(x) - u_n(y)|,$$

the announced continuity result follows from the above limit. The measurability statement follows from this continuity result and the measurability of $c$.

Proof of (2). To see this, take
| Description of \( L \) identified with the \( \| \cdot \| \) norm on \( Y \). The function \( \Lambda \) is given by
\[
\Lambda((f,g)) \Lambda := \| f \oplus g \|_c = \sup_{\mathcal{S}} \| f \oplus g \|/c, \quad (f,g) \in \mathcal{Y}_o.
\]
Identifying
\[
\mathcal{Y}_o \cong (C_A \oplus C_B)|_\mathcal{S}
\]
by means of \((f,g) \in \mathcal{Y}_o \mapsto f \oplus g|_\mathcal{S} \in (C_A \oplus C_B)|_\mathcal{S} \subset C|_\mathcal{S}\), the \( \| \cdot \|_\Lambda \)-completion \( \mathcal{Y} \) of \( \mathcal{Y}_o \) is identified with the \( \| \cdot \|_c \)-closure of \((C_A \oplus C_B)|_\mathcal{S}\) in \( U_c \).

**Description of \( \mathcal{L}, \mathcal{X}, \Lambda \) and \( \Lambda^* \).** The topological dual space of \( U_c \)
\[
\mathcal{L} := U_c^*
\]
is equipped with the dual norm
\[
\| \ell \|_c^* = \sup\{ \langle u, \ell \rangle; u \in U_c, \| u \|_c \leq 1 \}, \quad \ell \in U_c^*.
\]
The function \( \Lambda \) is given by
\[
\Lambda((f,g)) = \nu_{\{f \oplus g \leq c\}}, \quad f \oplus g \in (C_A \oplus C_B)|_\mathcal{S}
\]
and the corresponding norm is
\[
\Lambda((f,g)) = \| f \oplus g \|_c, \quad f \oplus g \in (C_A \oplus C_B)|_\mathcal{S}.
\]
The topological dual space of \( \mathcal{Y} \) is
\[
\mathcal{X} = \{(k_1, k_2) \in \mathcal{X}_o; \| (k_1, k_2) \|_\Lambda^* < \infty \}
\]
with
\[
\| (k_1, k_2) \|_\Lambda^* = \sup\{ \langle f, k_1 \rangle + \langle g, k_2 \rangle; (f,g) \in \mathcal{Y}_o, \| f \oplus g \|_c \leq 1 \} = \inf\{ \| \ell \|_c^*; \ell \in U_c^* \colon \ell_A = k_1, \ell_B = k_2 \}
\]
where this last equality is a direct consequence of the dual equality (2.3). Hence, \( k = (k_1, k_2) \in C_A^* \times C_B^* \) belongs to \( \mathcal{X} \) if and only if there exists some \( \ell(k) \in \mathcal{L} \) such that \( \langle f, k_1 \rangle + \langle g, k_2 \rangle = \langle f \oplus g, \ell(k) \rangle \) for all \((f,g) \in \mathcal{Y}_o \) and \( \lim_{n \to \infty} \langle u_n, \ell(k) \rangle = 0 \) for any sequence \((u_n)_{n \geq 1} \) in \( C_{AB} \) such that \( \lim_{n \to \infty} \| u_n \|_c = 0 \).

The function \( \Lambda^* \) is given by
\[
\Lambda^*((k_1, k_2)) = \sup\{ \langle f, k_1 \rangle + \langle g, k_2 \rangle; (f,g) \in \mathcal{Y}_o, f \oplus g \leq c \}, \quad k = (k_1, k_2) \in \mathcal{X}.
\]
Description of $\mathcal{X}^*$ and $T^*$. Seeing $\mathcal{X}$ as a subspace of $C_A^* \times C_B^*$, $\mathcal{X}^*$ is a subspace of $(C_A^* \times C_B^*)^*$. By the axiom of choice, there exists a subspace $\mathcal{Z}$ of $C_A^* \times C_B^*$ in direct sum with $\mathcal{X} : C_A^* \times C_B^* = \mathcal{X} \oplus \mathcal{Z}$. To any $\omega \in \mathcal{X}^*$, one associates its extension $\bar{\omega}$ to $C_A^* \times C_B^*$ characterized by $\bar{\omega}|\mathcal{Z} = 0$ and $\bar{\omega}|\mathcal{X} = \omega$. This permits us to define the marginal projections $\omega_A$ and $\omega_B$ and their tensor sum $\omega_A \oplus \omega_B \in U_c^*$ as follows. For all $(k_1, k_2) \in \mathcal{X}$,

$$
\langle \omega, (k_1, k_2) \rangle_{\mathcal{X}^*, \mathcal{X}} = \langle \bar{\omega}, (k_1, k_2) \rangle_{(C_A^* \times C_B^*)^*, C_A^* \times C_B^*} = \langle \bar{\omega}, (k_1, 0) + (0, k_2) \rangle_{(C_A^* \times C_B^*)^*, C_A^* \times C_B^*} := \langle \omega_A, k_1 \rangle_{C_A^*, C_A^*} + \langle \omega_B, k_2 \rangle_{C_B^*, C_B^*} := \langle \omega_A + \omega_B, \ell(k) \rangle_{U_c^*, U_c^*}
$$

For any $\omega \in \mathcal{X}^*$ and $\ell \in U_c'$, $(T^*\omega, \ell)_{U_c^*, U_c^*} = \langle \omega, (\ell_A, \ell_B) \rangle_{\mathcal{X}^*, \mathcal{X}} := \langle \omega_A + \omega_B, \ell \rangle_{U_c^*, U_c^*}$ which means that

$$
T^*\omega = \omega_A \oplus \omega_B \in U_c^*, \quad \omega \in \mathcal{X}^*. \quad (3.9)
$$

3.3. The connection with (MK). The connection with the Monge-Kantorovich problem is given at Proposition 3.11 below. The modified primal problem is

$$
\text{minimize } \Phi^*(\ell) \text{ subject to } \ell_A = \mu \text{ and } \ell_B = \nu, \quad \ell \in U_c' \quad (P_1)
$$

where

$$
\Phi^*(\ell) = \sup\{ \langle u, \ell \rangle; u \in U_c, u \leq c \}, \quad \ell \in U_c'.
$$

Definition 3.10.

(a) One says that $\ell \in U_c'$ acts as a probability measure if there exists $\tilde{\ell} \in \mathcal{P}_{AB}$ such that $\operatorname{supp} \tilde{\ell} \subset \operatorname{cl} \mathcal{S}$ and for all $u \in C_{AB}$, $\langle u|_S, \ell \rangle = \int_S u d\tilde{\ell}$. In this case, we write: $\ell \in \mathcal{P}_S$.

(b) One says that $\ell \in U_c'$ stands in $\mathcal{P}_c$ if there exists $\tilde{\ell} \in \mathcal{P}_c$ such that $\operatorname{supp} \tilde{\ell} \subset \operatorname{cl} \mathcal{S}$ and for all $u \in U_c$, $\langle u|_S, \ell \rangle = \int_S u d\tilde{\ell}$. In this case, we write: $\ell \in \mathcal{P}_c$.

Of course, if there exists $\tilde{\ell}$ satisfying (a), it belongs to $\mathcal{P}_c$ and is unique since any probability measure on a metric space is determined by its values on the continuous bounded functions. This explains why the notation $\ell \in \mathcal{P}_c$ in (b) is not misleading.

Note also that any probability measure $\ell \in \mathcal{P}_c$ has a support included in $\operatorname{cl} \mathcal{S}$. Since $A \times B$ is a metric space, for any $\ell \in \mathcal{P}_c$ acting as a measure, $\operatorname{supp} \ell$ in the sense of Definition 3.4 matches with the usual support of the measure $\ell$.

Proposition 3.11. For all $\ell \in U_c'$,

(a) $\Phi^*(\ell) < \infty \Rightarrow \ell \geq 0$.

(b) $\Phi^*(\ell) < \infty \Rightarrow \operatorname{supp} \ell \subset \operatorname{cl} \mathcal{S}$.

(c) $[\ell \geq 0, \operatorname{supp} \ell \subset \operatorname{cl} \mathcal{S}, \ell_A = \mu \text{ and } \ell_B = \nu] \Rightarrow \ell \in \mathcal{P}_S$ and

(d) for all $\ell \in \mathcal{P}_S$, $\Phi^*(\ell) = \int_S c d\ell \in [0, \infty]$.

It follows that $\operatorname{dom} \Phi^* \subset \mathcal{P}_c$ and the problems (MK) and (P1) share the same values and the same minimizers.

Proof. Clearly, the last statement follows from the first part of the proposition.

• Proof of (a). Suppose that $\ell \in U_c'$ is not in the nonnegative cone. This means that there exists $u_o \in U_c$ such that $u_o \geq 0$ and $\langle u_o, \ell \rangle < 0$. Since $u_o$ satisfies $\lambda u_o \leq 0 \leq c$ for all $\lambda < 0$, we have $\Phi^*(\ell) \geq \sup_{\lambda \leq 0} \langle \lambda u_o, \ell \rangle = +\infty$. Hence, $\Phi^*(\ell) < \infty$ implies that $\ell \geq 0$ and one can restrict our attention to the nonnegative $\ell$'s.
• Proof of (b). Suppose ad absurdum that $supp \ell \not\subseteq clS$. Then, there exists a nonnegative function $u_0 \in C_{AB}$ such that $\{u_0 > 0\} \cap S = \emptyset$ and $\langle u_0, \ell \rangle > 0$. As $\lambda u_0 \leq c|_{A \times B|S} \equiv \infty$ for all $\lambda > 0$, $\Phi^*(\ell) \geq sup_{\lambda > 0} \langle \lambda u_0, \ell \rangle = +\infty$.

• Proof of (c). Let us take $\ell \geq 0$ such that $supp \ell \subseteq clS$, $\ell_A = \mu$ and $\ell_B = \nu$. It is clear that $\langle 1, \ell \rangle = 1$. It remains to check that for any $\ell \in U'_c$

$$\left\lfloor \ell \geq 0, supp \ell \subseteq clS, \ell_A = \mu \text{ and } \ell_B = \nu \right\rfloor \Rightarrow \ell \text{ is } \sigma\text{-additive},$$

(3.12) rather than only additive. Since $A \times B$ is a metric space, one can apply an extension of the construction of Daniell’s integrals ([13], Proposition II.7.2) to see that $\ell$ acts as a measure if and only if for any decreasing sequence $(u_n)$ of continuous functions such that $0 \leq u_n \leq 1$ for all $n$ and $\lim_{n \to \infty} u_n = 0$ pointwise, we have $\lim_{n \to \infty} \langle u_n, \ell \rangle = 0$. This insures the $\sigma$-additivity of $\ell$.

Unfortunately, this pointwise convergence of $(u_n)$ is weaker than the uniform convergence with respect to which any $\ell \in U'_c$ is continuous. Except if $A \times B$ is compact, since in this special case, any decreasing sequence of continuous functions which converges pointwise to zero also converges uniformly on the compact space $clS$.

So far, we have only used the fact that $A \times B$ is a metric space. We now rely on the Polishness of $A$ and $B$ to get rid of this compactness restriction. It is known that any probability measure $P$ on a Polish space $X$ is tight (i.e. a Radon measure): for all $\epsilon > 0$, there exists a compact set $K_\epsilon \subset X$ such that $P(X \setminus K_\epsilon) \leq \epsilon$ ([13], Proposition II.7.3). As in addition a Polish space is completely regular, there exists a continuous function $f_\epsilon$ with a compact support such that $0 \leq f_\epsilon \leq 1$ and $\int_X (1 - f_\epsilon) dP \leq \epsilon$. This is true in particular for the probability measures $\mu \in \mathcal{P}_A$ and $\nu \in \mathcal{P}_B$ which specify the constraint in (MK). Hence, there exist $f_\epsilon \in C_A$ and $g_\epsilon \in C_B$ with compact supports such that $0 \leq f_\epsilon, g_\epsilon \leq 1$ and $0 \leq \int_A (1 - f_\epsilon) d\mu, \int_B (1 - g_\epsilon) d\nu \leq \epsilon$. It follows with the elementary fact: $0 \leq 1 - 2t \leq 2s - t$ for all $0 \leq s, t \leq 1$, that any nonnegative $\ell \in U'_c$ with $\ell_A = \mu$ and $\ell_B = \nu$ satisfies $0 \leq \langle (1 - f_\epsilon \otimes g_\epsilon), \ell \rangle \leq 2\epsilon$. With the following easy estimate $0 \leq \langle u_n, \ell \rangle \leq 2\epsilon + \langle u_n (f_\epsilon \otimes g_\epsilon), \ell \rangle$ and the compactness of the support of $f_\epsilon \otimes g_\epsilon$, one concludes that $\lim_{n \to \infty} \langle u_n, \ell \rangle = 0$ which proves (3.12).

• Proof of (d). Let us take $\ell \in \mathcal{P}_S$. As $c$ is bounded below and lower semicontinuous, there exists a sequence $(c_n)_{n \geq 1}$ in $C_{AB}$ such that $0 \leq c_n \leq c$ converges pointwise and increasingly to $c$. Therefore,

$$\int_S c d\ell \overset{(a)}{=} \lim_{n \to \infty} \int_S c_n d\ell \overset{(b)}{=} \lim_{n \to \infty} \langle c_n, \ell \rangle \leq \Phi^*(\ell),$$

(3.13)

where equality (a) holds by monotone convergence and equality (b) holds since $c_n$ belongs to $C_{AB}$.

Let us show the converse inequality: $\Phi^*(\ell) \leq \int_S c d\ell$. Let us first assume that $\ell \in \text{dom } \Phi^*$. It is proved at Lemma 3.14 below that for any $u \geq 0$ in $U_c$, $\langle u, \ell \rangle = \int_S u d\ell$. It follows that $\Phi^*(\ell) = sup\{\langle u, \ell \rangle; u \in U_c, u \leq c\} \leq \int_S c d\ell$.

If $\Phi^*(\ell) = \infty$, there exists a sequence $(u_n)_{n \geq 1}$ in $C_{AB}$ such that $0 \leq u_n \leq c$ and $\sup_n \int_S u_n d\ell = \infty$. Therefore, $\int_S c d\ell \geq \sup_n \int_S u_n d\ell = \infty$.

\textbf{Lemma 3.14.} For any $u \geq 0$ in $U_c$ and any $\ell \in \mathcal{P}_S \cap U'_c$ such that $\Phi^*(\ell) < \infty$, we have $\langle u, \ell \rangle = \int_S u d\ell$.

\textbf{Proof.} There exists a sequence $(u_n)_{n \geq 1}$ in $C_{AB}$ such that $\lim_{n \to \infty} u_n = u$ in $U_c$. As $\ell$ belongs to $U'_c$,

$$\lim_{n \to \infty} \int_S u_n d\ell = \lim_{n \to \infty} \langle u_n, \ell \rangle = \langle u, \ell \rangle,$$

(3.15)
On the other hand, $|u_n - u| \leq \|u_n - u\|_c c$ implies that $|u_n| \leq \|u\|_c + \|u_n - u\|_c c$. Hence, for some large enough $n_o$, 

$$|u_n| \leq (1 + \|u\|_c)c, \quad \forall n \geq n_o.$$ 

Together with (3.13), the assumption that $\Phi^*(\ell) < \infty$ and the dominated convergence theorem, this entails $\lim_{n \to \infty} \int_S u_n d\ell = \int_S u d\ell$. This and (3.15) lead us to $\langle u, \ell \rangle = \int_S u d\ell$ which is the desired result. \hfill \Box

4. An abstract characterization of optimality

The abstract characterization of optimality is stated in Theorem 4.6. It will allow us to obtain as corollaries, an explicit sufficient condition in Theorem 1.13 and an explicit necessary condition in Theorem 1.15. To prove it, one has to compute the extension $\Phi$. As it is the greatest convex $\sigma(U'_c, U'_c)$-lower semicontinuous extension of $\Phi = \iota_{\Gamma}$ and $\Gamma = \{u \in U'_c; u \leq c\}$ is a convex subset of $U'_o$, we have

$$\Phi^*(\xi) = \iota_{\overline{\Gamma}}(\xi), \quad \xi \in U''_c$$

where $\overline{\Gamma}$ is the $\sigma(U''_c, U''_c)$-closure of $\Gamma$. By (3.9), this gives

$$\Lambda(\omega) = \iota_{\overline{\Gamma}}(\omega_A \oplus \omega_B), \quad \omega \in X^*$$

and the extended problem $(\mathcal{D}')$ is

maximize $\langle \omega_A, \mu \rangle + \langle \omega_B, \nu \rangle$, $\omega \in X^*$ such that $\omega_A \oplus \omega_B \in \overline{\Gamma}$ (K)

Note that for this dual problem to be meaningful, it is necessary that $(\mu, \nu) \in X$. This is realized if $(\mu, \nu) \in \text{dom } \Lambda^*$ or equivalently if $\inf (MK) < \infty$.

Applying the first part of Theorem 2.4, taking into account the dual equality (3.3) and Proposition 3.11 gives the following

Lemma 4.2. Any $(\pi, \omega) \in P_{AB} \times \mathcal{H}_c$ is a solution to $(MK, K)$ if and only if

$$\begin{cases} 
(a) & \pi \in P(\mu, \nu, c); \\
(b) & \pi \in \partial_{U'_c} \Phi^* \eta \text{ where} \\
(c) & \eta = T^* \omega. 
\end{cases}$$

As $\Phi^*$ and $\Phi$ are mutually convex conjugates, (4.3-b) is equivalent to

$$\eta \in \partial_{U'_c} \Phi^* (\pi)$$

and also equivalent to Fenchel’s identity

$$\Phi^*(\pi) + \Phi(\eta) = \langle \eta, \pi \rangle$$

and by Proposition 3.11 this is also equivalent to

$$\begin{cases} 
\Phi(\eta) = 0 \\
\langle \eta, \pi \rangle = \int_{A \times B} cd\pi.
\end{cases}$$

Therefore, with Theorem 2.4 one obtains the

Theorem 4.6.

1. Any $(\pi, \omega) \in P(\mu, \nu, c) \times \mathcal{H}_c$ is a solution to $(MK, K)$ if and only if

$$\begin{cases} 
(a) & \omega_A \oplus \omega_B \in \overline{\Gamma} \\
(b) & \langle \omega, (\mu, \nu) \rangle = \int_{A \times B} cd\pi \end{cases}$$

(2) Suppose in addition that
\[(\mu, \nu) \in \text{dom} \partial \Lambda^*.
\] (4.8)

Then, \((MK, \overline{K})\) admits a solution in \(P(\mu, \nu, c) \times X^*\).

(3) Writing \(\eta = \omega_A \oplus \omega_B\), (4.3-b), (4.4), (4.5) and (4.7) are equivalent statements.

One was allowed to apply the second part of Theorem 2.4 under the constraint qualification (2.6)=(4.8). Let us give some details about this abstract requirement.

Remark 4.9. Note that if \(A \times B\) is an uncountable set, \((\mu, \nu) \notin \text{icordom} \Lambda^*\) for all \(\mu \in \mathcal{P}_A\), \(\nu \in \mathcal{P}_B\). Indeed, for all \(\pi \in \mathcal{P}(\mu, \nu, c)\) one can find \((a_o, b_o)\) such that with \(\delta_{(a_o, b_o)}\) the Dirac measure at \((a_o, b_o)\), \(\ell_t := t(b_o) + (1 - t)\pi \not\in 0\) for all \(t < 0\), so that \(\Phi^*_t(\ell_t) = +\infty\) (Proposition 3.11-a). This shows that \([\ell_0, \ell_1] = [\pi, \delta_{(a_o, b_o)}] \subset \text{dom} \Phi^*_t\) while \(\ell_t \not\in \text{dom} \Phi^*_t\) for all \(t < 0\). Hence, \((\mu, \nu) \notin \text{icordom} \Lambda^*\) and one has to consider the assumption (4.8) on \((\mu, \nu)\) rather than \((\mu, \nu) \in \text{icordom} \Lambda^*\).

Remarks 4.10 (Some remarks about \(\Phi^*(\ell), \Phi^*(|\ell|), \Lambda^*(k)\) and \(\Lambda^*(|k|)\)). Remark 4.9 shows that \(\text{icordom} \Lambda^*\) is empty in general. The following remarks are motivated by the problem of circumventing this restrictive property which stops us from applying Theorem 4.6 with an easy sufficient condition for (4.8).

(a) As \(U'_c\) is a Riesz space (it is the topological dual space of the Riesz space \(C(S)\)), any \(\ell\) in \(U'_c\) admits an absolute value \(|\ell| = \ell_+ + \ell_-\) and one can consider the convex and real-valued function \(\Phi^*(|\ell|) = \Phi^*(\ell_+) + \Phi^*(\ell_-)\) on \(U'_c\).

(b) Rather than the positively homogeneous sublinear function \(\Lambda^*(k)\) one could think of a \textit{real-valued} positively homogeneous function of the type \(\Lambda^*(|k|)\), since its icordom is nonempty. But, unlike \(U'_c\), \(X\) is not a Riesz space and \(\Lambda^*(|k|)\) is meaningless.

(c) The dual equality is \(\Lambda^*(k) = \inf \{\Phi^*(\ell) ; \ell \in U'_c, T_\ell = k\}\) and unlike \(\Phi^*, \) the effective domain of \(\Phi^*(|\ell|)\) is the whole space. It is natural to think of the function \(J(k) := \inf \{\Phi^*(|\ell|) ; \ell \in U'_c, T_\ell = k\}\) instead of \(\Lambda^*.\) The corresponding dual equality is \(J = \iota_T\), where \(T_\ell := \{(f', g') \in (C_A \oplus C_B)_S ; -c \leq f' + g' \leq c\}.\) It follows that \(J\) is a positively homogeneous sublinear function. But it is not true that \(J\) and \(\Lambda^*\) match on \(\text{dom} \Lambda^*\).

We have \(J \leq \Lambda^*\) and this inequality can be strict. To see this, let us consider the following example. Take \(A = \{a, \alpha\}, B = \{b, \beta\}, c(a, b) = c(a, \beta) = c(\alpha, b) = 0\) and \(c(\alpha, \beta) = 1.\) Clearly \(\Lambda^*(\delta_a, \delta_\beta) = c(\alpha, \beta) = 1\) while \(J(\delta_a, \delta_\beta) = \Phi^*(|\delta_{(a, b)} + \delta_{(a, b)}|) = 0.\)

Theorem 4.6 is the core of the extended saddle-point method applied to the Monge-Kantorovich problem. To prove a practical optimality criterion one still has to translate these abstract properties.

5. A SUFFICIENT CONDITION OF OPTIMALITY

The aim of this section is to prove Theorem 1.13.

5.1. Any finite strongly \(c\)-cyclically monotone plan is optimal. Next lemma gives a characterization of the closed convex hull \(\text{cl cv } A\) of a set \(A\) in terms of its support functional \(\iota_A^*\).

Lemma 5.1. Let \(X\) and \(Y\) be two topological vector spaces in duality. For any subset \(A\) of \(X\), one has
\[x \in \text{cl cv } A \iff \langle x, y \rangle \leq \iota_A^*(y), \forall y \in Y,
\]
where \(\iota_A^*(y) = \sup_{z \in A} \langle z, y \rangle, \forall y \in Y.\)
Proof. The biconjugate $\iota^*_A$ of the indicator function $\iota_A$ is its closed convex envelope which is also the indicator function $\iota_{\text{cl cv}} A$ of $\text{cl cv} A$. Therefore,

$$\begin{align*}
  x \in \text{cl cv} (A) \iff & \iota^*_A(x) = 0 \\
  \iff & \iota^*_A(x) \leq 0 \\
  \iff & \langle x, y \rangle \leq \iota^*_A(y), \forall y \in Y
\end{align*}$$

where the second equivalence follows from $\iota^*_A(x) = \sup \langle x, y \rangle - \iota^*_A(y) \geq \langle x, 0 \rangle - \iota^*_A(0) = 0$, for all $x \in X$. \hfill \Box

Proposition 5.2. Any finite strongly $c$-cyclically monotone plan is optimal.

This result is a restatement of [17, Theorem 2], see Theorem 1.11-b.

Proof. This is a corollary of the first (easy) part of Theorem 4.6. Let $\pi$ be a finite strongly $c$-cyclically monotone plan: There exist two measurable $[-\infty, \infty)$-valued functions $f$ and $g$ such that $f \oplus g$ satisfies (1.4):

$$\begin{align*}
  \left\{ \begin{array}{ll}
  f \oplus g & \leq c \quad \text{everywhere} \\
  f \oplus g & = c \quad \pi\text{-almost everywhere.}
  \end{array} \right.
\end{align*}$$

Let us first check that $(\mu, \nu)$ belongs to $X$. Indeed, $|(\mu, \nu)|^*_A = \inf \{ \|\ell\|^*_A; \ell \in U_c, \ell_A = \mu, \ell_B = \nu \} \leq \|\pi\|^*_c \leq \int c \, d\pi < \infty$. Let $E_o$ be the vector subspace of $\mathcal{X}$ spanned by $(\mu, \nu)$ and by means of Lemma 1.5, define the linear form on $E_o$

$$\langle \omega_o, t(\mu, \nu) \rangle := t \int f \oplus g \, d(\mu, \nu, c), \quad t \in \mathbb{R}.$$ 

As $f \oplus g = c$, $\pi$-almost everywhere and $\pi \in P(\mu, \nu, c)$, we have

$$\langle \omega_o, (\mu, \nu) \rangle = \int c \, d\pi. \quad (5.3)$$

On the other hand, thanks to (2.3) and Theorem 3.2-(1), $\Lambda^*(\mu, \nu) = \sup(\mathcal{K}) \geq \int f \oplus g \, d(\mu, \nu, c) = \langle \omega_o, (\mu, \nu) \rangle$. It follows that

$$\langle \omega_o, k \rangle \leq \Lambda^*(k), \quad \forall k \in E_o.$$

Denoting

$$\Upsilon := \{(f', g') \in (C_A \oplus C_B)|_{S}; f' \oplus g' \leq c\},$$

one has $\Lambda^*(k) = \iota^*_\Upsilon(k), k \in \mathcal{X}$. In particular, it is a $[0, \infty]$-valued positively homogeneous convex function on $\mathcal{X}$. By the analytic form of the Hahn-Banach theorem (see Remark 5.4 below), there exists an extension $\omega$ of $\omega_o$ to $\mathcal{X}$ which satisfies

$$\langle \omega, k \rangle \leq \iota^*_\Upsilon(k), \quad \forall k \in \mathcal{X}.$$ 

By Lemma 5.1, this means that $\omega$ belongs to the $\sigma(\mathcal{X}^*, \mathcal{X}^*)$-closure $\overline{\Upsilon}$ of $\Upsilon$. It is clear that $T_0^* \Upsilon \subset \Gamma$ and one sees that $T^* \overline{\Upsilon} \subset \overline{\Gamma}$ because of the $\sigma(\mathcal{X}^*, \mathcal{X}^*)\sigma(\mathcal{L}^*, \mathcal{L})$-continuity of $T^*: \mathcal{X}^* \to \mathcal{L}^*$, see [12, Lemma 4.13]. Since $T^* \omega = \omega_A \oplus \omega_B$, we have

$$\omega_A \oplus \omega_B \in \overline{\Gamma}.$$ 

Together with (5.3), this allows us to apply Theorem 4.6-(1) to obtain the desired result. \hfill \Box
Remark 5.4. We have used an unusual form of the Hahn-Banach theorem where the positively homogeneous sublinear function $\Lambda^*(k)$ is $(-\infty, +\infty]$-valued instead of real-valued. For a proof of this variant, rewrite without any change the proof the analytic version of Hahn-Banach theorem based on Zorn’s lemma; see for instance [6, Thm. 1.1].

The reason for not considering this extended version in the literature might be the following: To obtain separation by closed hyperplane, the positively homogeneous sublinear function of interest is the gauge of an open convex neighborhood of zero which is finite.

5.2. Measurability considerations. Strong $\gamma$-cyclical monotonicity revisited.

Definitions 5.5. Let $\gamma$ be a probability measure and $\Gamma$ be a set of probability measures on some measurable space.

1. A set $N$ is said to be $\gamma$-negligible if it is measurable and $\gamma(N) = 0$.
2. A set is said to be $\Gamma$-negligible if it is $\gamma$-negligible for all $\gamma \in \Gamma$.
3. A property holds $\Gamma$-almost everywhere if it holds everywhere except on a $\Gamma$-negligible set.
4. A function $h$ is said to be $\gamma$-measurable if there exists a $\gamma$-negligible set $N$ such that $1_{N \cap h}$ is measurable.
5. A function $h$ is said to be $\Gamma$-measurable if there exists a $\Gamma$-negligible set $N$ such that $1_{N \cap h}$ is measurable.

In particular the spaces $L_1(\mu)$ and $L_1(\nu)$ of all $\mu$ and $\nu$-integrable functions on $A$ and $B$ consist of classes with respect to the $\mu$ and $\nu$-almost everywhere equalities of $\mu$ and $\nu$-measurable functions.

Definitions 5.6 ($((\mu, \nu)$-measurability). These notions are meaningful only for a measurable product space $A \times B$.

1. A subset $N$ of $A \times B$ is said to be $(\mu, \nu)$-negligible if there exist two measurable sets $N_A \subset A$ and $N_B \subset B$ such that $\mu(N_A) = \nu(N_B) = 0$ and $N \subset (N_A \times B) \cup (A \times N_B)$.
2. A property holds $(\mu, \nu)$-almost everywhere if it holds everywhere except on a $(\mu, \nu)$-negligible set.
3. A function $\varphi$ on $A \times B$ is said to be $(\mu, \nu)$-measurable if there exists a $(\mu, \nu)$-negligible measurable set $N$ such that $1_{N \cap A} \varphi$ is measurable on $A \times B$.

Proposition 5.7.

1. Any $(\mu, \nu)$-negligible set is $P(\mu, \nu)$-negligible.

Hence, any $(\mu, \nu)$-measurable function is $P(\mu, \nu)$-measurable.

2. Let $f$ and $g$ be functions on $A$ and $B$. The following statements are equivalent.
   
   a) $f$ is $\mu$-measurable and $g$ is $\nu$-measurable;
   
   b) $f \oplus g$ is $(\mu, \nu)$-measurable;
   
   c) $f \oplus g$ is $P(\mu, \nu)$-measurable;
   
   d) $f \oplus g$ is $\mu \otimes \nu$-measurable.

Proof. • Proof of (1). Let $\pi \in P(\mu, \nu)$ and $N = (N_A \times B) \cup (A \times N_B)$ be a $(\mu, \nu)$-negligible measurable set. We have $\pi(N) \leq \pi(N_A \times B) + \pi(A \times N_B) = \mu(N_A) + \nu(N_B) = 0$.

Let us prove (2).

• Proof of (a) ⇒ (b). Let $N_A$ and $N_B$ be negligible sets such that $f1_{N_A}$ and $g1_{N_B}$ are measurable. Of course, $N = (N_A \times B) \cup (A \times N_B)$ is $(\mu, \nu)$-negligible and $1_{N \cap h} f \oplus g$ is measurable.

• Proof of (b) ⇒ (c). This follows from (1).

• Proof of (c) ⇒ (d). Immediate.
• Proof of \((d) \Rightarrow (a)\). Let \(S\) be a measurable subset of \(A \times B\) such that \(\mu \otimes \nu(S) = 1\) and \(1_s f \oplus g\) is measurable. For all \(a \in A\), denote \(S_a = \{b \in B; (a, b) \in S\}\) the \(a\)-section of \(S\). It is measurable and by Fubini’s theorem

\[
1 = \mu \otimes \nu(S) = \int_A \left[ \int_B 1_S(a, b) \nu(db) \right] \mu(da) = \int_A \nu(S_a) \mu(da).
\]

Therefore, \(\nu(S_a) = 1\), \(\mu\)-a.e. and there exists some \(a_o \in A\) such that \(\nu(S_{a_o}) = 1\). As a section of a measurable function, the function \(b \mapsto 1_{S_{ao}}(f(a_o) + g(b))\) is measurable.

It follows that \(1_{S_{ao}}g\) is measurable: this proves that \(g\) is \(\nu\)-measurable. A similar proof works for \(f\). □

It is immediate from the Definition 1.3 that a transport plan \(\pi \in P(\mu, \nu)\) is strongly \(c\)-cyclically monotone if and only if there exist a \(\mu\)-measurable function \(f\) on \(A\) and a \(\nu\)-measurable function \(g\) on \(B\) such that

\[
\begin{align*}
\{ & f \oplus g \leq c \quad (\mu, \nu)\text{-almost everywhere} \\
& f \oplus g = c \quad \pi\text{-almost everywhere.}
\end{align*}
\]

The underlying measurability properties of \(f \oplus g\) which are required by (5.8) are insured by Proposition 5.7.

By Proposition 5.7-1, if a property holds true \((\mu, \nu)\)-almost everywhere, then it is still true \(P(\mu, \nu)\)-almost everywhere and a fortiori \(P(\mu, \nu, c)\)-almost everywhere. Therefore,

\[
\begin{align*}
\{ & f \oplus g \leq c \quad P(\mu, \nu, c)\text{-almost everywhere} \\
& f \oplus g = c \quad \pi\text{-almost everywhere.}
\end{align*}
\]

is weaker than the strong \(c\)-cyclically monotonicity. Without changing a word to the proof of Proposition 5.2, one obtains the following sufficient condition of optimality.

**Theorem 1.13.** Let \(\pi \in P(\mu, \nu, c)\) be any finite plan. If there exist a \(\mu\)-measurable function \(f\) on \(A\) and a \(\nu\)-measurable function \(g\) on \(B\) which satisfy (5.9), then \(\pi\) is optimal.

### 5.3. The Counterexamples 1.12-(d,e).

They are optimal plans which are not strongly \(c\)-cyclically monotone but they both satisfy the weaker property (5.9).

- **Counterexample 1.12-(d).** Let \(A = B = [0, 1]\) both equipped with the Lebesgue measure \(\lambda = \mu = \nu\). Define \(c\) to be \(\infty\) above the diagonal and \(1 - \sqrt{a - b}\) for \(b \leq a\). The set \(P(\mu, \nu, c)\) is reduced to the uniform probability measure \(\pi\) on the diagonal which is a fortiori optimal. It is shown in [2] that \(\pi\) is not strongly \(c\)-cyclically monotone. But (5.9) is trivially satisfied.

- **Counterexample 1.12-(e).** Let \(A = B = \mathbb{N} \cup \{\omega\}\) where \(\omega\) is a “number” larger than all \(n \in \mathbb{N}\). Equip \(A\) and \(B\) with the discrete topology and define \(\mu = \nu\) with a full support. Define \(c(a, b) = \begin{cases} 
\infty & \text{for } a < b \\
1 & \text{for } a = b \\
0 & \text{for } a > b
\end{cases}\)

reduced to a single probability measure \(\pi\) which is a fortiori optimal and (5.9) is trivially satisfied. Nevertheless, it is proved in [4] that \(\pi\) is not strongly \(c\)-cyclically monotone.

### 6. A necessary condition of optimality

The aim of this section is to prove Theorem 1.15 which states that an optimal plan satisfies approximately (5.9).
6.1. A first approach to the necessary condition. We sketch a direct approach to the necessary condition and emphasize some problems which remain to be solved. The Kantorovitch dual equality (3.3) yields a maximizing sequence \( \{(f_n, g_n)\}_{n \geq 1} \) in \( C_A \times C_B \). Assume that \( \inf (MK) < \infty \) and define \( c_n := f_n + g_n \) so that \( c_n \leq c \) and \( \lim_{n \to \infty} \int c_n \, d\pi^* = \inf (MK) = \int c \, d\pi^* \) for any optimal plan \( \pi^* \). Clearly, \( c - c_n \geq 0 \) and \( \lim_{n \to \infty} \int (c - c_n) \, d\pi^* = 0 \). Hence, \( c_n \) converges to \( c \) in \( L^1(\pi^*) \) and one can extract a subsequence, denoted \( (c_k)_{k \geq 1} \), which converges to \( c \) pointwise \( \pi^* \)-almost everywhere. By a result of Borwein and Lewis [5, Corollary 3.4], \( (c_k)_{k \geq 1} \) converges pointwise \( \pi^* \)-almost everywhere to some sum function \( f \oplus g \). Therefore, \( c = f \oplus g \), \( \pi^* \)-almost everywhere.

The remaining problem of extending \( f \) and \( g \) such that \( f \oplus g \leq c \) everywhere is not obvious. By Tykhonov’s theorem, one can extract a subnet from \( (c_k)_{k \geq 1} \) which converges pointwise to a \([-\infty, +\infty]\)-valued function \( \tilde{c} \) such that \( \tilde{c} \leq c \) everywhere and \( \tilde{c} = c \), \( \pi^* \)-almost everywhere. Unfortunately, a subnet limit is not enough to insure that \( \tilde{c} \) is measurable. In addition, one cannot apply the above cited Borwein-Lewis convergence result since \([-\infty, +\infty]\) is not a group. Consequently, one cannot assert that \( \tilde{c} \) is of the sum form \( f \oplus g \).

6.2. A necessary condition. The idea in this section is to approximate \( \Phi = \iota_\Gamma \) by the sequence \( (\Phi_k)_{k \geq 1} \) with \( \Phi_k = \iota_{\Gamma_k} \) the convex indicator function of

\[
\Gamma_k := \{ u \in U_c; -kc \leq u \leq c \}, \quad k \geq 1.
\]

We define

\[
\Phi_k^\ast(\ell) = \| \ell^+ \|_c^* + k \| \ell^- \|_c^*, \quad \ell \in U_c'.
\]

its convex conjugate, where \( \| \ell \|_c^* = \sup \{ \langle u, \ell \rangle; u \in U_c : \| u \|_c \leq 1 \} \) is the dual norm on \( U_c' \). Note that as \( U_c' \) is a Riesz space, the positive and negative part \( \ell^+ \) and \( \ell^- \) are meaningful for all \( \ell \in U_c' \).

The restriction of \( \Phi_k^\ast \) to the set \( Q(\mu, \nu, c) \) of all \( q \in U_c' \) with first and second marginals \( \mu \) and \( \nu \) is denoted

\[
F_k(q) = \| q^+ \|_c^* + k \| q^- \|_c^*, \quad q \in Q(\mu, \nu, c) := \{ q \in U_c' ; q_A = \mu, q_B = \nu \}
\]

It is clear that \( (F_k)_{k \geq 1} \) converges pointwise and increasingly to the restriction \( F \) of \( \Phi^\ast \) to \( Q(\mu, \nu, c) \). By Proposition 3.11-c, the effective domain of \( F \) is \( P(\mu, \nu, c) \). Hence, \( F \) is the objective function of (MK):

\[
F(q) = \begin{cases} 
\int_{A \times B} c \, dq, & \text{if } q \in P(\mu, \nu, c) \ , \\
+\infty, & \text{otherwise}
\end{cases}, \quad q \in Q(\mu, \nu, c)
\]

Lemma 6.2.

(a) The following \( \Gamma \)-convergence result

\[
\Gamma - \lim_{k \to \infty} F_k = F
\]

holds true for both the \( \ast \)-weak topology \( \sigma(Q(\mu, \nu, c), U_c) \) and the strong topology associated with \( \| \cdot \|_c^* \) on \( Q(\mu, \nu, c) \);

(b) \( \min F = \lim_{k \to \infty} \inf F_k = \sup_k \min F_k \).

Proof. Since \( Q(\mu, \nu, c) \) is \( (U_c', U_c) \)-closed, one sees with the Banach-Alaoglu theorem that \( F_k \) is \( \sigma(Q(\mu, \nu, c), U_c) \)-inf-compact for all \( k \geq 1 \). It is a fortiori lower semicontinuous with respect to \( \sigma(Q(\mu, \nu, c), U_c) \) and \( \| \cdot \|_c^* \). As the sequence \( (F_k)_{k \geq 1} \) is increasing, it is also \( \sigma(Q(\mu, \nu, c), U_c) \)-equicoercive.

Now, (a) and (b) follow respectively from [7, Prop. 5.4 & Rem. 5.5] and [7, Thm. 7.8]. □
Let us denote \( M_\epsilon(F_k) \) the set of the \( \epsilon \)-minimizers of \( F_k \):
\[
M_\epsilon(F_k) = \{ q \in Q(\mu, \nu, c); F_k(q) \leq \inf F_k + \epsilon, \quad \epsilon > 0, k \geq 1 \}
\]
and \( M(F) \) the set of all the minimizers of \( F \).

**Lemma 6.3.** Clearly, the set of all the optimal plans is \( M(F) \).
Assume that \( P(\mu, \nu, c) \) is nonempty. Then \( M(F) \) is nonempty and
\[
M(F) = \bigcap_{\epsilon > 0, k \geq 1} \overline{M_\epsilon(F_k)}
\]
where \( \overline{M_\epsilon(F_k)} \) is the closure of \( M_\epsilon(F_k) \) with respect to \( \| \cdot \|_C ^* \).

**Proof.** Lemma 6.2 and [7, Thm. 7.19] give us \( M(F) = \bigcap_k K^{-}\text{lim inf}_{k \rightarrow \infty} M_\epsilon(F_k) \) where \( K^{-}\text{lim inf}_{k \rightarrow \infty} M_\epsilon(F_k) \) is the liminf in the sense of Kuratowski associated with the topology generated by \( \| \cdot \|_C ^* \). Since \( (F_k)_{k \geq 1} \) is increasing, we obtain \( K^{-}\text{lim inf}_{k \rightarrow \infty} M_\epsilon(F_k) = \bigcap_{k \geq 1} \overline{M_\epsilon(F_k)} \) which completes the proof. \( \square \)

This result invites us to learn more about \( M_\epsilon(F_k) \). We denote \( U''_c \) the strong bidual of \( U_c \) and denote \( \| \cdot \|_C \) its norm. Let \( \Sigma_k \) be the \( \sigma(U''_c, U'_c) \)-closure of
\[
\Sigma_k = \{ f + g \in (C_A \oplus C_B)_S; -kc \leq f + g \leq c \}
\]
and \( \overline{\Phi}_k \) the largest convex \( \sigma(U''_c, U'_c) \)-lower semicontinuous extension of \( \Phi_k \) to \( U''_c \). We denote \( \Lambda^*_k \) the analogue of \( \Lambda^* \) where \( \Phi \) is replaced by \( \Phi_k \).

**Lemma 6.4.** For each \( \epsilon > 0, k \geq 1 \) and \( q \in M_\epsilon(F_k) \), there exist \( \bar{\eta} \in \Sigma_k, \bar{\eta} \in U''_c \) and \( \ell \in U'_c \) such that
\[
\| \ell - q \|_C \leq \sqrt{\epsilon}, \| \bar{\eta} - \eta \|_C \leq \sqrt{\epsilon} \quad \text{and} \quad \ell \in \partial \Phi_k(\bar{\eta}).
\]

**Proof.** Since the effective domain of \( \Phi_k \) is the whole space \( U'_c \), the dual equality insures that the effective domain of \( \Lambda^*_k \) is the whole space \( X \). In particular,
\[
\partial \Lambda^*_k(\mu, \nu) \neq \emptyset.
\]
This non-emptiness is crucial. The approximation \( F_k \) of \( F \) was introduced to circumvent the problem of knowing whether \( \partial \Lambda^*(\mu, \nu) \) is empty or not. One is allowed to apply Theorem 2.4 and Proposition 2.9.

Let \( \bar{q} \) be a minimizer of \( F_k \). We have \( \bar{q} \in Q(\mu, \nu, c) \) and \( \partial \Phi_k(\bar{q}) \) is nonempty. More precisely, with \( \bar{\omega} \in \partial \Lambda^*_k(\mu, \nu) \) and \( \bar{\eta} = \bar{\omega}_A \oplus \bar{\omega}_B \) we have \( \bar{\eta} \in \partial \Phi_k(\bar{q}) \) and
\[
\langle \bar{\eta}, q \rangle = \langle \bar{\eta}, \bar{q} \rangle, \quad \forall q \in Q(\mu, \nu, c).
\] (6.5)

Fenchel’s equality is \( \Phi_k^*(\bar{q}) = \langle \bar{\eta}, \bar{q} \rangle - \overline{\Phi}_k(\bar{\eta}) \). But, \( \overline{\Phi}_k(\bar{\eta}) \) is equal to 0 or \(+\infty\) and \( \Phi_k^*(\bar{q}) > -\infty \). Hence, \( \overline{\Phi}_k(\bar{\eta}) = 0 \) and
\[
\{ \bar{\eta} \in \Sigma_k \} \quad \{ \Phi_k^*(\bar{q}) = \langle \bar{\eta}, q \rangle \}
\]

As the level sets of \( \Phi_k \) are \( \| \cdot \|_C \)-bounded, by Proposition 2.9-b’ we have \( \bar{\eta} \in U''_c \). Now, we consider the topological duality \( \langle U'_c, U''_c \rangle \).

Let us take \( q \) in \( M_\epsilon(F_k) \). With (6.5) one sees that \( \langle \bar{\eta}, \bar{q} \rangle = \langle \bar{\eta}, q \rangle \). It follows that \( \Phi_k^*(\bar{q}) \leq \Phi_k^*(\bar{q}) + \epsilon = \langle \bar{\eta}, q \rangle + \epsilon = \langle \bar{\eta}, q \rangle - \overline{\Phi}_k(\bar{\eta}) + \epsilon \). This means that \( q \) stands in the \( \epsilon \)-subdifferential \( \partial \overline{\Phi}_k(\bar{\eta}) \) of \( \overline{\Phi}_k \) at \( \bar{\eta} \). One completes the proof applying Ekeland’s principle [10, Thm. 6.2]. \( \square \)

**Lemma 6.6.** Let \( \pi \) be an optimal plan. There exists a sequence \( (\hat{l}_k)_{k \geq 1} \) in \( U'_c \) and two sequences \( (\bar{\eta}_k)_{k \geq 1} \) and \( (\tilde{\eta}_k)_{k \geq 1} \) in \( U''_c \) such that
\[
(i) \quad \lim_{k \rightarrow \infty} \| \hat{l}_k - \pi \|_C = 0
\]
and for each $k \geq 1$:

(i) $\tilde{\eta}_k \in \partial \Phi_k^*(\ell_k)$;

(ii) $\|\tilde{\eta}_k - \eta_k\|_c \leq 1/k$ and $\tilde{\eta}_k \in \Sigma_k$;

(iv) $\|\tilde{\ell}_k\|_* \leq (\inf (MK) + 2)/k$.

**Proof.** By Lemma 6.3, there exists a sequence $(q_k)_{k \geq 1}$ such that

$$\lim_{k \to \infty} \|q_k - \pi\|_*^c = 0 \quad (6.7)$$

and $q_k \in M_{\epsilon_k}(F_k)$ for each $k \geq 1$, where $\lim_{k \to \infty} \epsilon_k = 0$.

By Lemma 6.4, for each $k \geq 1$, there exist $\tilde{\ell}_k \in U'_c$, $\tilde{\eta}_k \in \Sigma_k$ and $\tilde{\eta}_k \in U'_c$ such that

$$\|\tilde{\ell}_k - q_k\|_*^c \leq \sqrt{\epsilon_k}, \|\tilde{\eta}_k - \eta_k\|_c \leq \sqrt{\epsilon_k} \text{ and } \tilde{\eta}_k \in \partial \Phi_k^*(\tilde{\ell}_k).$$

Since $\Phi_k^*$ is $k$-Lipschitz, we have

$$\Phi_k^*(\tilde{\ell}_k) \leq \Phi_k^*(q_k) + k\|\tilde{\ell}_k - q_k\|_c$$

$$\leq \inf (MK) + \epsilon_k + k\sqrt{\epsilon_k}$$

$$\leq \inf (MK) + 2$$

taking

$$\epsilon_k = 1/k^2.$$ 

It follows from (6.1) that $\|\tilde{\ell}_k\|_* \leq \Phi_k^*(\tilde{\ell}_k)/k \leq (\inf (MK) + 2)/k$. One concludes with $\|\tilde{\ell}_k - \pi\|_c \leq \|\tilde{\ell}_k - q_k\|_*^c + \|q_k - \pi\|_*^c \leq 1/k + \|q_k - \pi\|_*^c$ and (6.7). \hfill \Box

**Lemma 6.8.** Let $\eta \in U''_c$ be in the $\sigma(U''_c, U'_c)$-closure of $\Sigma_k$ for some $k \geq 1$. For each probability measure $p \in \mathcal{P}_c$, there exists a function $\tilde{\eta}$ in $L_1(p)$ such that

$$\begin{cases}
(a) & \langle \eta, h, p \rangle = \int_{A \times B} h\tilde{\eta} \, dp, \quad \forall h \in L_\infty(p) \\
(b) & \tilde{\eta} \in \text{cl}_{L_1(p)}(\Sigma_k)
\end{cases} \quad (6.9)$$

where $\text{cl}_{L_1(p)}(\Sigma_k)$ is the closure of $\Sigma_k$ in $L_1(p)$ with respect to its usual strong topology.

**Proof.** For any bounded measurable function $h$ on $A \times B$ we have

$$|\langle \eta, h, p \rangle| \leq \|\eta\|_{U''_c} \int_{A \times B} |h|c \, dp \quad (6.10)$$

since $|\langle \eta, h, p \rangle| \leq \|\eta\|_{U''_c} \|h\|_{U'_c}$ with $\|h\|_{U'_c} = \int_{A \times B} |h|c \, dp$. Let $(h_k)_{k \geq 1}$ be a sequence of bounded measurable functions such that the sequence $(\|h_k\|)_{k \geq 1}$ decreases pointwise to zero. By (6.10) and dominated convergence, we have $\lim_{k \to \infty} \langle \eta, h, p \rangle = 0$. This means that $h \mapsto \langle \eta, h, p \rangle$ is $\sigma$-additive: there exists a measure $\rho$ such that $\langle \eta, h, p \rangle = \int_{A \times B} h \, dp$, $\forall h$. By (6.10), $\rho$ is absolutely continuous with respect to $p$: there exists $\tilde{\eta}$ in $L_1(p)$ such that (6.9-a) holds.

Let $\{u_\alpha\}_\alpha$ be a net in $\Sigma_k$ such that $\lim_\alpha u_\alpha = \eta$. For all $h$ in $L_\infty(p)$,

$$\int_{A \times B} h\tilde{\eta} \, dp = \langle \eta, h, p \rangle = \lim_\alpha \langle u_\alpha, h, p \rangle = \lim_\alpha \int_{A \times B} h u_\alpha \, dp.$$ 

This means that $\tilde{\eta}$ is in the $\sigma(L_1(p), L_\infty(p))$-closure of $\Sigma_k$. As $\Sigma_k$ is convex, this implies (6.9-b). \hfill \Box

We are now ready to give the proof of Theorem 1.15.

**Theorem 1.15.** Let $\pi$ be any optimal plan and let us take $\epsilon > 0$ and $p \in \mathcal{P}_c$. Then, there exist $\varphi \in L_1(\pi + p)$, $f \in C_A$, $g \in C_B$ and a measurable subset $D \subset A \times B$ such that

(1) $\varphi = c$, $1_{(S,D)}\pi$-almost everywhere;

(2) $\int_D (1 + c) \, d\pi \leq \epsilon$;
Proof. By Lemma 6.6, for any $\epsilon > 0$, there exist $k$ large enough, $\tilde{\ell}$ in $U'_c$ and $\tilde{\eta}, \tilde{\eta}$ in $U''_c$ such that

\begin{align*}
(3) & \quad -c/\epsilon \leq \varphi \leq c, \quad (\pi + p)\text{-almost everywhere;} \\
(4) & \quad -c/\epsilon \leq f \oplus g \leq c, \quad everywhere; \\
(5) & \quad \|\varphi - f \oplus g\|_{L_1(\pi + p)} \leq \epsilon.
\end{align*}

Let $\hat{\eta}$ and $\tilde{\eta}$ be the functions in $L_1(\pi + p)$ which are built from $\tilde{\eta}$ and $\tilde{\eta}$ as in Lemma 6.8 and satisfy: $(\hat{\eta}, h, (\pi + p)) = \int_{A \times B} h \hat{\eta} d(\pi + p)$ and $(\hat{\eta}, h, (\pi + p)) = \int_{A \times B} h \tilde{\eta} d(\pi + p)$ for all $h \in L_\infty(\pi + p)$. By (iii) and (6.9-b), there exist $f \in C_A$ and $g \in C_B$ such that $-kc \leq f \oplus g \leq c$ and

\[ \|\hat{\eta} - f \oplus g\|_{L_1(\pi + p)} \leq \epsilon. \]

With the notation of Lemma 6.8, we have $\|\hat{\eta}\|_{L_1(\pi)} \leq [\int_{A \times B} c \, dp]\|\eta\|_c$ for all $\eta \in U''_c$. Taking $\varphi = \hat{\eta}$, this and (iv) give $\|\varphi - \hat{\eta}\|_{L_1(\pi + p)} \leq \epsilon \int_{A \times B} c \, d(\pi + p)$. Therefore,

\[ \|\varphi - f \oplus g\|_{L_1(\pi + p)} \leq \left(1 + \int_{A \times B} c \, d(\pi + p)\right) \epsilon. \]

By (ii), we have $\hat{\eta} \in \text{dom } \mathcal{T}_k = \Sigma_k$. Hence, $-kc \leq \varphi = \hat{\eta} \leq c, \quad (\pi + p)\text{-a.e.}$

Since $U_c$ is identified with $C_S$ which is a subspace of $C_S$, see (3.7), any $\ell \in U'_c$ is the restriction to $C_S$ of a continuous linear form on $C_S$. Therefore it can be uniquely decomposed as $\ell = \ell^a + \ell^s$ where $\ell^a$ is a measure and $\ell^s$ is singular with $\|\ell\|_c = \|\ell^a\|_c^* + \|\ell^s\|_c^*$. By (i), we have $\|\hat{\ell} - \pi\|_c^* \leq 2\epsilon$. Since $\pi$ is a measure, its singular part vanishes: $\pi^s = 0$. It follows that $\|\hat{\ell}^a - \pi\|_c^* \leq 2\epsilon$ where $\hat{\ell}^a$ is the measure part of $\hat{\ell}$. Therefore, the nonnegative measures $\hat{\ell}^a$ and $\pi$ are concentrated on the same set except for a measurable set $D$ such that $\int_D c \, d(\hat{\ell}^a + \pi) \leq 2\epsilon$.

Finally, (ii) implies that $c = \varphi, \quad \hat{\ell}^a$-almost everywhere (and also that $-kc = \varphi, \quad \hat{\ell}^a$-almost everywhere). One completes the proof, putting everything together and replacing $\epsilon$ by $\epsilon/C$ with an appropriate constant $C$. \qed
