Stabilization of Persistently Excited Linear Systems by Delayed Feedback Laws

Guilherme Mazanti∗

March 18, 2014

Abstract

This paper considers the stabilization to the origin of a persistently excited linear system by means of a linear state feedback, where we suppose that the feedback law is not applied instantaneously, but after a certain positive delay (not necessarily constant). The main result is that, under certain spectral hypotheses on the linear system, stabilization by means of a linear delayed feedback is indeed possible, generalizing a previous result already known for non-delayed feedback laws.

Keywords: stabilization, switched systems, persistent excitation, delayed feedback

1 Introduction

Consider a control system of the form

\[ \dot{x}(t) = Ax(t) + \alpha(t)Bu(t), \quad x(t) \in \mathbb{R}^d, \ u(t) \in \mathbb{R}^m, \ \alpha \in \mathcal{G}, \]  

(1.1)

where \( x \) is the state variable, \( u \) is a control input, \( A \) and \( B \) are matrices of appropriate dimensions, and \( \alpha \) belongs to a certain class \( \mathcal{G} \) of measurable scalar signals \( \alpha : \mathbb{R}_+ \to [0, 1] \). This corresponds to the introduction on the linear control system \( \dot{x} = Ax + Bu \) of a certain signal \( \alpha \) that determines when and how much the control \( u \) is active. Note that, when \( \alpha \) takes its values on \{0, 1\}, (1.1) is actually a switched system between the dynamics of the uncontrolled system \( \dot{x} = Ax \) and the controlled one \( \dot{x} = Ax + Bu \).

Several different phenomena may be modeled by signal \( \alpha \) in (1.1), such as a failure in the transmission of the control \( u \) to the plant, a time-varying parameter affecting the control efficiency, or the allocation of control resources, among other possible phenomena. We are interested in general on robust control techniques of (1.1) with respect to \( \alpha \): we suppose that \( \alpha \) is not precisely known and we wish our control strategy for (1.1) to be chosen independently of \( \alpha \) and to be valid for any signal \( \alpha \) in a certain class \( \mathcal{G} \).

The problem of controlling (1.1) by a suitable choice of \( u \) is obviously not interesting when \( \alpha \equiv 0 \), or when \( \alpha \) is zero for a large amount of time, since in this case the control \( u \) has a very limited effect on (1.1). The class \( \mathcal{G} \) should thus ensure that the control input has a

guilherme.mazanti@polytechnique.edu
sufficient amount of action on the system. Among the possible choices for $\mathcal{G}$, the class of $(T, \mu)$-persistently exciting signals has attracted much interest recently (see, for instance, [8–11, 14, 20, 25, 27], and also [21] for a similar condition) and, for $T \geq \mu > 0$, it consists on the signals $\alpha \in L^\infty(\mathbb{R}_+, [0, 1])$ such that, for every $t \in \mathbb{R}_+$,

$$
\int_{t-\tau}^{t+\tau} \alpha(s) ds \geq \mu.
$$

The class of these signals $\alpha$ is noted $\mathcal{G}(T, \mu)$. Further examples of systems similar to (1.1) where the persistent excitation condition appears are given in [8, 10, 20], where the motivation for the use of persistently exciting signals is also more deeply discussed.

The condition of persistence of excitation (1.2) arises naturally in identification and adaptive control problems (see, e.g., [1–3, 7, 23]). In this context, we are led to study systems of the kind $\dot{x} = -P(t)x$, $x \in \mathbb{R}^d$, where $P(t)$ is a symmetric non-negative definite matrix for every $t$. If $P$ is bounded and has bounded derivative, it has been shown in [27] that the persistence of excitation of $P$, in the sense that $\alpha(t) = \xi^T P(t) \xi$ is $(T, \mu)$-persistently exciting for all unitary vectors $\xi \in \mathbb{R}^d$ and for certain constants $T \geq \mu > 0$ independent of $\xi$, is a necessary and sufficient condition for the global exponential stability of $\dot{x} = -P(t)x$.

We consider the problem of stabilization of system (1.1) to the origin by means of a linear state feedback $u = -Kx$, where we require the choice of the gain matrix $K$ not to depend on a particular signal $\alpha$ but instead on the class $\mathcal{G}(T, \mu)$. In many practical situations, this feedback cannot be done instantaneously, for a certain state $x(t)$ may not be available for measure before a certain delay $\tau$ has elapsed, and so the state measured in time $t$ is actually $x(t - \tau(t))$. Due to the several practical situations where time lags are introduced by sensors, actuators, or the transmission or processing of signals, the study of delayed systems in general is of much interest, and specially in the context of control systems [5, 13, 15, 26, 28]. In several situations, the time-delay appearing in a system is not known exactly and may change with the time, and the literature usually classifies these delays in two types: slowly-varying delays, where its derivative satisfies $|\tau(t)| < 1$, and fast-varying delays, without constraints on the derivative of the delay. In this paper, we take as possible delays $\tau$ measurable functions taking their values on a certain set $\mathcal{T} \subset \mathbb{R}_+$, and we are thus in the framework of fast-varying delays.

This paper considers the problem of stabilization of (1.1) by a delayed feedback $u(t) = -Kx(t - \tau(t))$, where the delay $\tau(t)$ may depend on $t$, and the closed-loop system becomes

$$
\begin{alignat}{2}
\dot{x}(t) &= Ax(t) - \alpha(t) BKx(t - \tau(t)), \\
\alpha \in \mathcal{G}(T, \mu), &\quad \tau \in L^\infty(\mathbb{R}_+, \mathcal{T})
\end{alignat}
$$

(1.3)

where $\mathcal{T} \subset \mathbb{R}_+$ is the set where the delay $\tau$ takes its values. The goal of this paper is to present a stabilization result for system (1.3), showing that, under certain hypotheses on $A$ and $B$, given $T \geq \mu > 0$ and $\tau_0 \geq 0$, there exist a neighborhood $\mathcal{T}$ of $\tau_0$ in $\mathbb{R}_+$ and $K \in \mathcal{M}_{m,d}(\mathbb{R})$ such that, for any $\alpha \in \mathcal{G}(T, \mu)$ and any delay function $\tau \in L^\infty(\mathbb{R}_+, \mathcal{T})$, system (1.3) is exponentially stable, uniformly with respect to $\alpha$ and $\tau$. This generalizes [11, Theorem 3.2], where the same result is given in the case of the non-delayed feedback $u(t) = -Kx(t)$, corresponding thus to $\mathcal{T} = \{0\}$.

Notice that (1.3) is related to switched linear systems with delays, since, when $\alpha(t)$ takes its values on $\{0, 1\}$, (1.3) becomes a switched system between the non-delayed uncontrolled dynamics $\dot{x} = Ax$ and the delayed one $\dot{x}(t) = Ax(t) - BKx(t - \tau(t))$, under the constraint of persistence of excitation given by (1.2). Several results exist concerning switched systems with delays, presented for instance in [16, 19, 22, 32–34]. Many of them apply Lyapunov function and functional techniques to obtain conditions on the systems, the delay and the switching law that...
guarantee stability under constrained or arbitrary switching, such as [16,19,33]. The constraints on the switching law usually take the form of an average dwell time, as in [32–34], or a strategy to design a switching rule, as in [16]. In this paper, we consider that $\alpha$ is an unknown signal satisfying the condition of persistence of excitation (1.2), which is different from the usual hypothesis of average dwell time used for switched systems since $\alpha$ may be active at arbitrarily small time intervals at each time. Our main technique consists on studying (1.3) through a time-contraction procedure and a limit system, which has been proved to be useful when studying persistently exciting systems in [11] but, up to our knowledge, it has not been previously used to study delayed switched systems.

Let us comment briefly on the technique used in [11] to consider the stabilizability of (1.3) in the non-delayed case. The main problem when dealing with the class $\mathcal{S}(T,\mu)$ is that a signal $\alpha \in \mathcal{S}(T,\mu)$ may be zero on certain time intervals, and so the system follows its uncontrolled dynamics $\dot{x} = Ax$. On the other hand, for every $\rho > 0$, it is known by a result from [12] that one can choose a linear feedback $u(t) = -Kx(t)$ that stabilizes (1.1) uniformly with respect to $\alpha \in L^\infty(\mathbb{R}_+,[\rho,1])$. The main idea in [11] is to perform a change of variables corresponding to a time contraction by a factor $\nu > 0$, which transforms a $(T,\mu)$-signal $\alpha$ into a $(T/\nu,\mu/\nu)$-signal $\alpha_\nu$ with $\alpha_\nu(t) = \alpha(\nu t)$. It is possible to show that the family $(\alpha_\nu)_{\nu > 0}$ admits a weak-$*$ convergent subsequence $(\alpha_{\nu_n})_{n \in \mathbb{N}}$ in $L^\infty(\mathbb{R}_+,\mathbb{R},[0,1])$ with $\nu_n \to +\infty$ and that any weak-$*$ subsequential limit $\alpha_*$ of $(\alpha_\nu)_{\nu > 0}$ as $\nu \to +\infty$ satisfies $\alpha_*(t) \geq \mu/T$ almost everywhere. The idea is thus to study a certain limit system obtained as $\nu \to +\infty$, for which stabilization can be obtained using the result from [12] mentioned above. It can then be shown by a limit procedure that the same feedback gain $K$ also stabilizes a time-contracted system for a certain $\nu > 0$ large enough, and one may finally adapt such a feedback gain $K$ in order to obtain a stabilizer for the original system.

This time-contraction technique used in [11] is well-adapted to deal with delays in the feedback, since a delay $\tau(t)$ in the original system will correspond to a delay $\frac{\tau(\nu t)}{\nu}$ in the time-contraction system. We may thus expect to obtain a non-delayed limit system as $\nu \to +\infty$ similar to the one obtained in [11] and to conclude the stabilizability of the original system by a similar argument. This intuition is actually true, as proved in Theorem 2.5 below, where we prove our stabilizability result by following the same time-contraction argument of the proof of [11, Theorem 3.2].

In their article [11], the authors first prove their stabilization result in the particular case where the dynamics are given by the Jordan block $J_2$ (see (3.1) below), since it is a representative example containing most of the difficulties of the proof of the general case. We also treat the case of the Jordan block separately in this article (see Theorem 3.1), but in this particular case we have a stronger result, showing that stabilizability is possible for any bounded interval $T \subset \mathbb{R}_+$ where the delay $\tau \in L^\infty(\mathbb{R}_+,T)$ may take its values, whereas in the general case we may only guarantee stabilizability for delays $\tau$ which are perturbations around a certain constant prescribed value $\tau_0$. This difference between the statements of our result in the general case and in the particular case of the Jordan block is more deeply discussed in Section 5.

The plan of the paper is the following. In Section 2, we present the notations and definitions used throughout this paper and recall the previous result of [11]. We then proceed to prove, in Section 3, the main theorem of this paper in the particular case of the Jordan block, which allows us to highlight the main ideas of the proof in a setting where the notations are much clearer than in the general case, and also leads to a stronger result than in the general case. The proof of our main theorem is presented in Section 4, and Section 5 discusses the results we obtained, and specially the difference in the statements of Theorems 3.1 and 2.5. The proofs of
some technical lemmas used in this paper are given in the Appendices A and B.

2 Notations, Definitions and Previous Results

In this paper, \( \mathcal{M}_{d,m}(\mathbb{R}) \) denotes the set of \( d \times m \) matrices with real coefficients, which is denoted simply by \( \mathcal{M}_d(\mathbb{R}) \) when \( d = m \). As usual, we identify column matrices in \( \mathcal{M}_{d,1}(\mathbb{R}) \) with vectors in \( \mathbb{R}^d \). The identity matrix in \( \mathcal{M}_d(\mathbb{R}) \) is denoted by \( \text{Id}_d \) and \( 0_{d \times m} \in \mathcal{M}_{d,m}(\mathbb{R}) \) denotes the matrix whose entries are all zero, the dimensions being possibly omitted if they are implicit. The block-diagonal matrix whose diagonal blocks are the square matrices \( a_1, \ldots, a_d \) is denoted by \( \text{diag}(a_1, \ldots, a_d) \). The notation \( \|x\| \) indicates both the Euclidean norm of a vector \( x \in \mathbb{R}^d \) and the associated matrix norm. The real and imaginary parts of a complex number \( z \) are denoted by \( \Re(z) \) and \( \Im(z) \) respectively. The sets \( \mathbb{R}_+ \) and \( \mathbb{N}^* \) denote, respectively, the sets of the non-negative real numbers \( \mathbb{R}_+ = [0, +\infty) \) and the positive integers \( \mathbb{N}^* = \{1, 2, 3, 4, \ldots \} \). For two topological spaces \( X \) and \( Y \), we denote by \( \mathcal{C}^0(X,Y) \) the set of all continuous functions from \( X \) to \( Y \).

Throughout this paper, we consider the system

\[
\dot{x}(t) = Ax(t) + \alpha(t)Bu(t), \quad x(t) \in \mathbb{R}^d, \ u(t) \in \mathbb{R}^m, \ \alpha \in \mathcal{S}(T, \mu), \tag{2.1}
\]

where \( A \in \mathcal{M}_d(\mathbb{R}), B \in \mathcal{M}_{d,m}(\mathbb{R}) \), and we take persistently exciting signals \( \alpha \) in the class \( \mathcal{S}(T, \mu) \) defined as follows.

**Definition 2.1.** Let \( T, \mu \) be two positive constants with \( T \geq \mu \). We say that a measurable function \( \alpha : \mathbb{R}_+ \to [0, 1] \) is a \( (T, \mu) \)-signal if, for every \( t \in \mathbb{R}_+ \), one has

\[
\int_t^{t+\tau} \alpha(s)ds \geq \mu.
\]

The set of \( (T, \mu) \)-signals is denoted by \( \mathcal{S}(T, \mu) \). System (2.1) with \( \alpha \in \mathcal{S}(T, \mu) \) is called a persistently excited system (PE system for short).

We shall consider the problem of stabilizability of system (2.1) by means of a delayed linear state feedback \( u(t) = -K x(t - \tau(t)) \), where the delay \( \tau \) is a function in \( L^\infty(\mathbb{R}_+, \mathcal{T}) \) for a certain bounded set \( \mathcal{T} \subset \mathbb{R}_+ \) and \( K \in \mathcal{M}_{m,d}(\mathbb{R}) \). With this feedback, system (2.1) takes the form

\[
\dot{x}(t) = Ax(t) - \alpha(t)BKx(t - \tau(t)), \quad \alpha \in \mathcal{S}(T, \mu), \quad \tau \in L^\infty(\mathbb{R}_+, \mathcal{T}). \tag{2.2}
\]

Note that, for \( T \geq \mu > 0 \) and \( \mathcal{T} \subset \mathbb{R}_+ \) bounded, for every \( \alpha \in L^\infty(\mathbb{R}_+, [0, 1]) \) and every \( \tau \in L^\infty(\mathbb{R}_+, \mathcal{T}) \), (2.2) satisfies the Carathéodory conditions for delayed equations (see, for instance, [13, Section 2.6 and Theorem 6.1.1]), and so, noting \( r = \sup \mathcal{T} \), for any given initial condition \( x_0 \in \mathcal{C}^0([-r, 0], \mathbb{R}^d) \), (2.2) admits a unique continuous solution \( x \) defined on \( [-r, +\infty) \), which is absolutely continuous on \( \mathbb{R}_+ \), coincides with \( x_0 \) on \( [-r, 0] \), and satisfies \( \dot{x}(t) = Ax(t) - \alpha(t)BKx(t - \tau(t)) \) for almost every \( t \in \mathbb{R}_+ \). In order to make explicit the dependence of the solution \( x \) on \( \tau, x_0, \alpha \) and \( K \), we denote \( x(t) = x(t; \tau, x_0, \alpha, K) \).

In the context of delayed systems, stability is defined in terms of the uniform norm of the initial condition (see, for instance, [13, Chapter 5]), which motivates the following definition.
Definition 2.2. Let $T \geq \mu > 0$ and $\mathcal{J}$ be a bounded subset of $\mathbb{R}_+$, and denote $r = \sup \mathcal{J}$. We say that $K \in M_{m,d}(\mathbb{R})$ is a $(T, \mu, \mathcal{J})$-stabilizer for (2.2) if there exist constants $C \geq 1$ and $\gamma > 0$ such that, for every $\alpha \in \mathcal{S}(T, \mu)$, every $\tau \in L^\infty(\mathbb{R}_+, \mathcal{J})$, and every initial condition $x_0 \in C^0([-r, 0], \mathbb{R}^d)$, the solution $x(t; \tau, x_0, \alpha, K)$ of (2.2) satisfies
\[
\|x(t; \tau, x_0, \alpha, K)\| \leq Ce^{-\gamma \tau} \sup_{s \in [-r, 0]} \|x_0(s)\|, \quad \forall t \geq 0.
\]

Remark 2.3. If $K$ is a $(T, \mu, \mathcal{J})$-stabilizer for (2.2), then, for every constant $\alpha_* \in [\mu/r, 1]$ and every constant delay $\tau_* \in \mathcal{J}$, the linear delayed system
\[
\dot{x}(t) = Ax(t) - \alpha_* BK(t - \tau_*)
\]
(2.3)
is exponentially stable. This is an important remark, since the stability and stabilization of systems with a constant delay of the form (2.3) can be more easily studied (see, for instance, [26, 28]), giving rise to necessary conditions for $K$ to be a $(T, \mu, \mathcal{J})$-stabilizer. We shall use this approach later in Example 5.1.

Let us recall that a pair of matrices $(A, B) \in M_d(\mathbb{R}) \times M_{d,m}(\mathbb{R})$ is said to be stabilizable if there exists a matrix $K \in M_{m,d}(\mathbb{R})$ such that $A - BK$ is Hurwitz. This is equivalent to saying that there exists an invertible matrix $P \in M_d(\mathbb{R})$ such that
\[
PAP^{-1} = \begin{pmatrix} A_1 & A_3 \\ 0 & A_2 \end{pmatrix}, \quad PB = \begin{pmatrix} B_1 \\ 0 \end{pmatrix},
\]
where $A_2$ is Hurwitz and $(A_1, B_1)$ is controllable. Stabilizability of a pair $(A, B)$ means that the linear control system $\dot{x} = Ax + Bu$ admits a linear state feedback $u = -Kx$ such that the closed-loop system $\dot{x} = (A - BK)x$ is exponentially stable, and thus, in order to achieve the required stabilizability property for system (2.2), the stabilizability of $(A, B)$ is a necessary condition when $0 \in \mathcal{J}$. This is what motivates us to consider only stabilizable pairs $(A, B)$ in what follows.

The stabilizability of (2.2) by means of a non-delayed feedback law has been studied in [11] in the case of a single-input system, i.e., when $m = 1$, and it has been generalized to the multi-input case in [10]. In terms of Definition 2.2, this result can be stated as follows.

Theorem 2.4. Let $(A, B) \in M_d(\mathbb{R}) \times M_{d,m}(\mathbb{R})$ be a stabilizable pair and assume that the eigenvalues of $A$ have non-positive real part. Then, for every $T \geq \mu > 0$, there exists a $(T, \mu, \{0\})$-stabilizer for (2.2).

The hypothesis that the eigenvalues of $A$ have non-positive real part may seem restrictive, but it was shown in [11] that Theorem 2.4 is not true for certain stabilizable pairs $(A, B)$ and certain values of $T, \mu$ when $A$ admits an eigenvalue with positive real part. This is actually an effect of the signal $\alpha$ in the dynamics of the system; note that, when $\alpha(t) \in \{0, 1\}$, the closed-loop system actually switches between the dynamics given by $\dot{x} = Ax$ and $\dot{x} = (A - BK)x$, and the phenomena related to this switch, such as the overshooting phenomenon, may lead to the non-stabilizability of the switched system when $A$ has an eigenvalue with positive real part, as detailed in [11]. For more general information on the behavior of switched systems, we refer to [4, 6, 17, 18, 24, 30].

The main result of this paper is the following generalization of Theorem 2.4.

Theorem 2.5. Let $(A, B) \in M_d(\mathbb{R}) \times M_{d,m}(\mathbb{R})$ be a stabilizable pair and assume that the eigenvalues of $A$ have non-positive real part. Then, for every $T \geq \mu > 0$ and every $\tau_0 \geq 0$, there exists a neighborhood $\mathcal{J}$ of $\tau_0$ in $\mathbb{R}_+$ and a $(T, \mu, \mathcal{J})$-stabilizer for (2.2).
We prove this theorem here by generalizing the proof given in [11] in the non-delayed case. The main point is that the time-contraction argument given in [11], when applied to a delayed system, reduces the effects of the delay in the system, in such a way that the limit system obtained by making the time-contraction parameter tend to infinity is essentially the same in the delayed and the non-delayed cases. In order to highlight these main ideas, we first consider a particular case of Theorem 2.5.

3 The $d$-Integrator

Before turning to the proof of Theorem 2.5, let us first consider the particular case where the dynamics of the system are given by the $d$-integrator, defined by the Jordan block

\[
J_d = \begin{pmatrix}
0 & 1 & 0 & \cdots & 0 & 0 \\
0 & 0 & 1 & \cdots & 0 & 0 \\
0 & 0 & 0 & \cdots & 0 & 0 \\
\vdots & \vdots & \vdots & \ddots & \vdots & \vdots \\
0 & 0 & 0 & \cdots & 0 & 1 \\
0 & 0 & 0 & \cdots & 0 & 0
\end{pmatrix}
\]  

(3.1)

and by taking $m = 1$ and $B = (0 \cdots 0 1)^T \in M_{d,1}(\mathbb{R})$. This particular case will allow us to highlight the main ideas of the proof of Theorem 2.5, since it contains most of the difficulties of the general case. Furthermore, we can give in this case a stronger result, showing the existence of a $(T, \mu, \tau)$-stabilizer for any bounded interval $T \subset \mathbb{R}_+$, and not only for perturbations around a certain value as in the general case of Theorem 2.5.

**Theorem 3.1.** Let $A = J_d$, $B = (0 \cdots 0 1)^T \in \mathbb{R}^d$, and let $T \geq \mu > 0$ and $r > 0$ be given. Then there exists a $(T, \mu, [0, r])$-stabilizer $K \in M_{1,d}(\mathbb{R})$ for (2.2).

**Proof.** The proof follows the same idea of the proof of [11, Theorem 3.1]: we first perform a change of variables corresponding to a time contraction in order to relate $(T, \mu, [0, r])$-stabilizers to $(T/\nu, \mu/\nu, [0, r/\nu])$-stabilizers for $\nu > 0$. We then study the stabilizability of a certain limit system, and this allows us to conclude the stabilizability of the original system for a certain $\nu > 0$ large enough, thanks to the continuity result presented in the Appendix A.

**Step 1. Time contraction**

The system we consider is

\[
\dot{x}(t) = J_d x(t) - \alpha(t) BK x(t - \tau(t)),
\]

\[
\alpha \in \mathcal{G}(T, \mu), \tau \in L^\infty([\mathbb{R}_+, [0, r]]).
\]

(3.2)

For $\nu > 0$, we define

\[
D_{d, \nu} = \text{diag}(\nu^{d-1}, \ldots, \nu, 1),
\]

(3.3)

which satisfies the relations

\[
\nu D_{d, \nu}^{-1} J_d D_{d, \nu} = J_d, \quad D_{d, \nu} B = B.
\]

(3.4)
Noting, for simplicity, \( x(t) = x(t; \tau, x_0, \alpha, K) \), and defining
\[
x_{v}(t) = D_{d,v}^{-1} x(v t),
\]
\( x_v \) satisfies
\[
\frac{d}{dt} x_v(t) = J_d x_v(t) - \alpha(t) v BKD_d, v x_v \left( t - \frac{\tau \langle v t \rangle}{v} \right)
\]
and hence
\[
x_v(t) = x (t; \frac{\tau \langle v \cdot \rangle}{v}, D_d^{-1}_v x_0 (v \cdot), \alpha_v, v KD_d, v)
\]
with \( \alpha_v(t) = \alpha(v t) \), which is a \((T/v, \mu/v)\)-signal. Thus \( K \) is a \((T, \mu, [0, r])\)-stabilizer for (3.2) if and only if \( v KD_d, v \) is a \((T/v, \mu/v, [0, r/v])\)-stabilizer. This equivalence is crucial in what follows: instead of looking for a \((T, \mu, [0, r])\)-stabilizer for (3.2), we look for a \((T/v, \mu/v, [0, r/v])\)-stabilizer for a certain \( v > 0 \) large enough. The technique is thus to study a certain limit system obtained as \( v \to +\infty \), obtain a stabilizer for this non-delayed system and then show that this stabilizer is actually a \((T/v, \mu/v, [0, r/v])\)-stabilizer for a certain \( v > 0 \) large enough.

**Step 2. Limit system**

We turn to the system
\[
\dot{x}(t) = J_d x(t) - \alpha_\ast(t) BK x(t),
\]
\[
\alpha_\ast \in L^\infty (\mathbb{R}_+, [\mu/T, 1]).
\]
It has been proved in [11, Theorem 3.1], using a result from [12], that one can find \( K \in \mathcal{M}_{1,d}(\mathbb{R}) \) and a positive definite matrix \( S \in \mathcal{M}_d(\mathbb{R}) \), both independent of the particular signal \( \alpha_\ast \in L^\infty (\mathbb{R}_+, [\mu/T, 1]) \), such that (3.7) is globally uniformly exponentially stable and \( V(x) = x^T S x \) decreases along all trajectories of (3.7), uniformly with respect to \( \alpha_\ast \). In particular, there exists a time \( \sigma \) such that every trajectory of (3.7) starting in \( B^V_1 = \{ x \in \mathbb{R}^d \mid V(x) \leq 2 \} \) at time 0 lies in \( B^V_1 = \{ x \in \mathbb{R}^d \mid V(x) \leq 1 \} \) for every time larger than \( \sigma \).

**Step 3. Study of (3.6) through the limit system.**

We wish to deduce from the conclusion obtained in the previous step that (3.2) admits a \((T/v, \mu/v, [0, r/v])\)-stabilizer for a certain \( v > 0 \) large enough. We claim that, for some \( v > 0 \) large enough, every trajectory of
\[
\dot{x}(t) = J_d x(t) - \alpha(t) BK x(t - \tau(t)),
\]
\[
\alpha \in \mathcal{G}(T/v, \mu/v), \tau \in L^\infty (\mathbb{R}_+, [0, r/v]),
\]
with initial condition \( x_0 \in C([r/v, 0], B^V_2) \) stays in \( B^V_1 \) for every time larger than \( 2\sigma \). In particular, by linearity, this will imply that \( K \) is a \((T/v, \mu/v, [0, r/v])\)-stabilizer of (3.2) and thus \( v^{-1} KD_d^{-1} \) is a \((T, \mu, [0, r])\)-stabilizer, concluding the proof. To prove this, assume, by contradiction, that for every \( n \in \mathbb{N}^+ \) there exist \( \tau_n \in L^\infty (\mathbb{R}_+, [0, r/n]), x_0^{(n)} \in C^0([-r/n, 0], B^V_2), \alpha_n \in \mathcal{G}(T/n, \mu/n), \) and \( t_n \in [2\sigma, 4\sigma] \) such that, for every \( n \in \mathbb{N}^+ \),
\[
x \left( t_n; \tau_n, x_0^{(n)}, \alpha_n, K \right) \notin B^V_1.
\]
Up to the extraction of a subsequence, we can suppose that, as \( n \to +\infty \), \( t_n \to t_\ast \in [2\sigma, 4\sigma] \), \( x_0^{(n)}(0) \to x_0^0 \in B^V_2 \), and \( \alpha_n \to \alpha_\ast \in L^\infty (\mathbb{R}_+, [0, 1]) \) weakly*; we also note that \( \tau_n(t) \to 0 \)
as \( n \to +\infty \) uniformly on \( t \in \mathbb{R}_+ \). Then, applying Lemma A.1 proved in the Appendix A, we obtain that \( x(t_n; \tau_n, x_0^{(n)}, \alpha_n, K) \) converges to \( x(t_\ast; 0, x_\ast^0, \alpha_\ast, K) \) as \( n \to +\infty \). We also note that, by [11, Lemma 2.5], \( \alpha_\ast(t) \geq \mu / T \) almost everywhere in \( \mathbb{R}_+ \), and so, by our previous study of (3.7), since \( t_\ast \geq 2\sigma \), by linearity, we have

\[
V(x(t_\ast; 0, x_\ast^0, \alpha_\ast, K)) \leq \frac{1}{2}.
\]

This contradicts (3.8), establishing the desired result. \( \blacksquare \)

## 4 Main Result

We now turn to the proof of our main result, Theorem 2.5. For a given stabilizable pair of matrices \((A, B) \in \mathbb{M}_d(\mathbb{R}) \times \mathbb{M}_{d,m}(\mathbb{R})\) and for given \( T \geq \mu > 0 \) and \( \tau_0 \geq 0 \), we wish to find an interval \( \mathcal{T} \subset \mathbb{R}_+ \) of admissible perturbations around \( \tau_0 \) and a \((T, \mu, \mathcal{T})\)-stabilizer for (2.2).

### Proof of Theorem 2.5.

#### Step 1. Reduction to a canonical form

Notice that we may reduce the theorem to the case where \((A, B)\) is controllable, \(m = 1\), and all the eigenvalues of \(A\) lie on the imaginary axis; this is detailed in Lemmas B.1, B.2, and B.3 in the Appendix B. We thus suppose from now on that \((A, B)\) is controllable, \(m = 1\), and \(\Re(\lambda) = 0\) for every eigenvalue \(\lambda\) of \(A\). We also reduce \((A, B)\) to a normal form with which it shall be easier to work.

#### Lemma 4.1. Suppose \((A, B) \in \mathbb{M}_d(\mathbb{R}) \times \mathbb{R}^d\) is a controllable pair and \(\Re(\lambda) = 0\) for every eigenvalue \(\lambda\) of \(A\). Then, up to a linear transformation of coordinates, (2.1) can be written as

\[
\begin{align*}
\dot{x}_0(t) &= J_{r_0} x_0(t) + \alpha(t) b^0 u(t), & x_0(t) &\in \mathbb{R}_n^{r_0}, \\
\dot{x}_j(t) &= (\omega_j A^{(j)} + J_{r_j}) x_j(t) + \alpha(t) b^j u(t), & x_j(t) &\in \mathbb{R}_j^{2r_j}, & j = 1, \ldots, h,
\end{align*}
\]

(4.1)

where the spectrum of \(A\) is \(\sigma(A) = \{ \pm i\omega_j, j = j_0, j_0 + 1, \ldots, h \} \) with all the \(\omega_j \geq 0\) distinct, \(j_0 = 1\) if \(0 \notin \sigma(A)\), \(j_0 = 0\) and \(\omega_0 = 0\) otherwise; \(r_j\) is the algebraic multiplicity of the eigenvalue \(i\omega_j\) (with \(r_0 = 0\) if \(0 \notin \sigma(A)\)); \(J_{r_j}\) is the real Jordan block defined in (3.1): \(J_n^C \in \mathbb{M}_{2n}(\mathbb{R})\) is the Jordan block for complex eigenvalues,

\[
J_n^C = \begin{pmatrix}
0_{2 \times 2} & \text{Id}_2 & 0_{2 \times 2} & \cdots & 0_{2 \times 2} & 0_{2 \times 2} \\
0_{2 \times 2} & 0_{2 \times 2} & \text{Id}_2 & \cdots & 0_{2 \times 2} & 0_{2 \times 2} \\
0_{2 \times 2} & 0_{2 \times 2} & 0_{2 \times 2} & \text{Id}_2 & \cdots & 0_{2 \times 2} & 0_{2 \times 2} \\
0_{2 \times 2} & 0_{2 \times 2} & 0_{2 \times 2} & 0_{2 \times 2} & \cdots & 0_{2 \times 2} & 0_{2 \times 2} \\
\vdots & \vdots & \vdots & \vdots & \ddots & \vdots & \vdots \\
0_{2 \times 2} & 0_{2 \times 2} & 0_{2 \times 2} & 0_{2 \times 2} & \cdots & 0_{2 \times 2} & \text{Id}_2 \\
0_{2 \times 2} & 0_{2 \times 2} & 0_{2 \times 2} & 0_{2 \times 2} & \cdots & 0_{2 \times 2} & 0_{2 \times 2}
\end{pmatrix},
\]

that is, \(J_n^C = J_n \otimes \text{Id}_2\) in terms of the Kronecker product; \(A^{(j)} = \text{diag}(A_0, \ldots, A_0) \in \mathbb{M}_{2r_j}(\mathbb{R})\) with

\[
A_0 = \begin{pmatrix}
0 & 1 \\
-1 & 0
\end{pmatrix};
\]
and $b^0$ and $b^j$ are respectively the vectors of $\mathbb{R}^{r_0}$ and $\mathbb{R}^{2r_j}$ with all the coordinates equal to zero except the last one that is equal to one.

This lemma was proved in [11] during the proof of Theorem 3.2 therein; for the sake of completeness, we present briefly its proof in the Appendix B.

**Step 2. Time contraction**

We work from now on with system (4.1). Given $K \in \mathcal{M}_1_d(\mathbb{R}^d)$, we decompose $K$ in blocks as $K = (K_0 \quad K_1 \quad \cdots \quad K_h)$ with $K_0 \in \mathcal{M}_{1,r_0}(\mathbb{R})$, $K_j \in \mathcal{M}_{1,2r_j}(\mathbb{R})$, $j = 1, \ldots, h$, so that the feedback law $u(t) = -Kx(t - \tau(t))$ is written as $u(t) = -K_0x_0(t - \tau(t)) - \sum_{j=1}^h K_jx_j(t - \tau(t))$. As in the proof of Theorem 3.1, we perform a change of time-space variables in the closed-loop system corresponding to a time contraction. Define

$$y_0(t) = D_{r_0,v}^{-1}x_0(vt),$$

$$y_j(t) = (D_{r_j,v}^C)^{-1} e^{-vt\omega_jA^{(j)}}x_j(vt), \quad j = 1, \ldots, h,$$

with $D_{n,v}$ as in (3.3), satisfying (3.4), and

$$D_{n,v}^C = D_{n,v} \otimes \text{Id}_2 = \text{diag}(v^{n-1}, v^{n-1}, \ldots, v, v, 1, 1) \in \mathcal{M}_{2n}(\mathbb{R}),$$

which satisfies

$$v(D_{r_j,v}^C)^{-1}J_{r_j}^CD_{r_j,v}^C = J_{r_j}^C, \quad D_{r_j,v}^Cb^j = b^j, \quad j = 1, \ldots, h.$$

Then $y_0, y_1, \ldots, y_h$ satisfy

$$
\begin{cases}
\dot{y}_0(t) = J_{r_0,y_0}(t) - \alpha_v(t)b^0 \left[ K_{0,v}y_0 \left( t - \frac{\tau(v)}{v} \right) + \sum_{\ell=1}^h K_{\ell,v}e^{(v-\tau(v))\omega_\ell A^{(\ell)}}y_\ell \left( t - \frac{\tau(v)}{v} \right) \right], \\
\dot{y}_j(t) = J_{r_j,y_j}(t) - \alpha_v(t)e^{-vt\omega_jA^{(j)}}b^j \left[ K_{0,v}y_0 \left( t - \frac{\tau(v)}{v} \right) + \sum_{\ell=1}^h K_{\ell,v}e^{(v-\tau(v))\omega_\ell A^{(\ell)}}y_\ell \left( t - \frac{\tau(v)}{v} \right) \right], \quad j = 1, \ldots, h, 
\end{cases}
$$

with $\alpha_v(t) = \alpha(vt)$, $K_{0,v} = vK_0D_{r_0,v}$, $K_{\ell,v} = vK_\ell D_{r_\ell,v}^C$ for $\ell = 1, \ldots, h$, and where we use that $A^{(j)}D_{r_j,v}^C = D_{r_j,v}^CA^{(j)}$ and $A^{(j)}J_{r_j}^C = J_{r_j}^CA^{(j)}$ for $j = 1, \ldots, h$. This shows that the gain $K = (K_0 \quad K_1 \quad \cdots \quad K_h)$ is a $(T, \mu, T)$-stabilizer for (4.1) if and only if the gain $K_v = (K_{0,v} \quad K_{1,v} \quad \cdots \quad K_{h,v})$ is a $(T/v, \mu/v, T/v)$-stabilizer for (4.2), where $T/v = \{t/v \mid t \in T\}$.

**Step 3. Choice of the feedback family**

We turn to the problem of finding a neighborhood $T$ of $x_0$ in $\mathbb{R}_+$ and a $(T/v, \mu/v, T/v)$-stabilizer for (4.2) for a certain $v > 0$, which will imply the theorem. We shall look for such a stabilizer $K_v$ under a particular form. We write $b_0 = (0 \quad 1)^T$ and we take $K_v = (K_{0,v} \quad K_{1,v} \quad \cdots \quad K_{h,v})$ with

$$K_{0,v} = \mathcal{K}_0, \quad \mathcal{K}_0 = (k_0^0 \quad \cdots \quad k_0^{r_0}) \in \mathcal{M}_{1,r_0}(\mathbb{R})$$

$$K_{j,v} = \mathcal{K}_j \otimes b_0^T e^{r_0\omega_jA_0}, \quad \mathcal{K}_j = (k_j^0 \quad \cdots \quad k_j^{r_j}) \in \mathcal{M}_{1,2r_j}(\mathbb{R}), \quad j = 1, \ldots, h.$$
Now, since \( A^{(\ell)} = \text{Id}_{r_\ell} \otimes A_0 \), we have, for \( \ell = 1, \ldots, h \), that
\[
K_{\ell,\nu}e^{(v - \tau(v))\omega A^{(\ell)}} = K_{\ell} \otimes b_0^T e^{(v - \tau(v)+\tau_0)\omega A_0} = \\
= K_{\ell} \otimes b_0^T e^{(v - \tau(v))\omega A_0} + K_{\ell} \otimes \left[ b_0^T e^{(v - \tau(v))\omega A_0} \left( e^{-(\tau(v) - \tau_0)\omega A_0} - \text{Id}_2 \right) \right].
\]

Noting \( \tilde{b}^j \in \mathbb{R}^j \) the vector with all coordinates equal to zero except the last one that is equal to one, we have \( b^j = \tilde{b}^j \otimes b_0 \), and thus \( e^{-v\omega A^{(j)}b^j} = \tilde{b}^j \otimes e^{-v\omega A_0 b_0} \). We finally write, for \( j, \ell \in \{1, \ldots, h\} \),
\[
C^{(v)}_{00}(t) = \alpha_v(t), \\
C^{(v)}_{0j}(t) = \alpha_v(t)b_0^T e^{v\omega A_0}, \\
C^{(v)}_{j0}(t) = \alpha_v(t)e^{-v\omega A_0}b_0, \\
C^{(v)}_{j\ell}(t) = \alpha_v(t)e^{-v\omega A_0}b_0b_0^T e^{v\omega A_0}, \quad (4.4) \\
P^{(v)}_{00}(t) = P^{(v)}_{0j}(t) = 0, \\
P^{(v)}_{0j}(t) = \alpha_v(t)b_0^T e^{v\omega A_0} \left[ e^{-(\tau(v) - \tau_0)\omega A_0} - \text{Id}_2 \right], \\
P^{(v)}_{j\ell}(t) = \alpha_v(t)e^{-v\omega A_0}b_0b_0^T e^{v\omega A_0} \left[ e^{-(\tau(v) - \tau_0)\omega A_0} - \text{Id}_2 \right],
\]
and thus system (4.2) can be written under the form
\[
\begin{cases}
\dot{y}_0(t) = J_{\tau_0} y_0(t) - \sum_{\ell=0}^{h} [b^\ell K_{\ell} \otimes (C^{(v)}_{0\ell}(t) + P^{(v)}_{0\ell}(t))] y_\ell \left( t - \frac{\tau(v)}{\nu} \right), \\
\dot{y}_j(t) = J^{c}_{\tau_0} y_j(t) - \sum_{\ell=0}^{h} [\tilde{b}^j K_{\ell} \otimes (C^{(v)}_{j\ell}(t) + P^{(v)}_{j\ell}(t))] y_\ell \left( t - \frac{\tau(v)}{\nu} \right), \quad j = 1, \ldots, h. 
\end{cases} \quad (4.5)
\]

We can arrange all the matrices \( C^{(v)} \) in a \((2h+1-j_0) \times (2h+1-j_0)\) symmetric matrix and all the matrices \( P^{(v)} \) in a \((2h+1-j_0) \times (2h+1-j_0)\) matrix respectively as
\[
C^{(v)}(t) = \begin{pmatrix} C_{j\ell}^{(v)}(t) \end{pmatrix}_{j_0 \leq j, \ell \leq h}, \quad P^{(v)}(t) = \begin{pmatrix} P_{j\ell}^{(v)}(t) \end{pmatrix}_{j_0 \leq j, \ell \leq h}. \quad (4.6)
\]

We take from now on \( \mathcal{J} \) under the form \( \mathcal{J} = [\tau_0 - r, \tau_0 + r] \cap \mathbb{R}_+ \) for a certain \( r > 0 \) to be chosen, and so
\[
\left\| P^{(v)}_{j\ell}(t) \right\| \leq \left\| e^{-(\tau(v) - \tau_0)\omega A_0} - \text{Id}_2 \right\| = \sqrt{2 \left[ 1 - \cos((\tau(v) - \tau_0)\omega_j) \right]} \leq |(\tau(v) - \tau_0)\omega_j| \leq r \Omega \quad (4.7)
\]
with \( \Omega = \max\{\omega_j \mid j = j_0, \ldots, h\} \).

**Step 4. Limit system**

We wish to study (4.5) for large \( \nu \) through a limit system approaching its behavior as \( \nu \to +\infty \), as we did with (3.6) in Theorem 3.1. The following lemma, proved later on in Appendix B, provides a stability result for the limit system that is used in the next step to study (4.5).
Lemma 4.2. Consider the system

\[
\begin{align*}
\dot{y}_0(t) &= J_{\tau_0}y_0(t) - \sum_{\ell=0}^{h} [b^0\mathcal{X}_\ell \otimes (C_{0\ell}(t) + P_{0\ell}(t))] y_{\ell}(t), \\
\dot{y}_j(t) &= J_j^C y_j(t) - \sum_{\ell=0}^{h} [b^j\mathcal{X}_\ell \otimes (C_{j\ell}(t) + P_{j\ell}(t))] y_{\ell}(t), \quad j = 1, \ldots, h,
\end{align*}
\]

(4.8)

where \(y_0 \in \mathbb{R}^n\), \(y_j \in \mathbb{R}^{2r_j}\), \(J_0\) and \(J_j^C\) are the Jordan blocks defined above, \(b^0\) and \(b^j\) are the vectors defined above, \(\mathcal{X}_j \in \mathcal{M}_{1,r_j}(\mathbb{R})\) are constant matrices, \(j = j_0, \ldots, h\), \(C_*, P_* \in L^\infty(\mathcal{M}_{2h+1-j_0}(\mathbb{R}))\) and the \(2 \times 2\) time-dependent matrices \(C_{j\ell}, P_{j\ell}\), \(1 \leq j, \ell \leq h\), the \((1-j_0) \times 2\) time-dependent matrices \(C_{0\ell}, P_{0\ell}\), the \(2 \times (1-j_0)\) time-dependent matrices \(C_{j0}, P_{j0}\) and the signals \(C_{00}, P_{00}\) are defined by the relations

\[
C_*(t) = (C_{j\ell}(t))_{j_0 \leq j, \ell \leq h}, \quad P_*(t) = (P_{j\ell}(t))_{j_0 \leq j, \ell \leq h},
\]

(4.9)

and we also assume that

\[
\|P_{j\ell}(t)\| \leq r\Omega, \quad \text{for almost every } t \in \mathbb{R}_+, \forall j, \ell \in \{j_0, \ldots, h\}.
\]

(4.10)

We write \(y = (y_0^T, y_1^T, \ldots, y_h^T)^T\).

Let \(\xi > 0\). Then there exist \(C \geq 1, \gamma > 0, r > 0\), and \(\mathcal{X}_j \in \mathcal{M}_{1,r_j}(\mathbb{R}), j = j_0, \ldots, h\), such that, for every symmetric matrix \(C_* \in L^\infty(\mathcal{M}_{2h+1-j_0}(\mathbb{R}))\) satisfying \(C_*(t) \geq \xi \Id_{2h+1-j_0}\) almost everywhere, every \(P_* \in L^\infty(\mathcal{M}_{2h+1-j_0}(\mathbb{R}))\) satisfying (4.10) and every solution \(y\) of (4.8), we have

\[
\|y(t)\| \leq Ce^{-\gamma t} \|y(0)\|, \quad \forall t \geq 0.
\]

Step 5. Study of (4.5) through the limit system

To conclude the proof, we deduce the stability of (4.5) from that of (4.8) in the same way as we did in the proof of Theorem 3.1. Take \(T \geq \mu > 0\) and \(\tau_0 \geq 0\). By \([11, \text{Lemma } 2.5]\), there exists \(\xi > 0\) depending only on \(T, \mu\) and \(\omega_j, j = j_0, \ldots, h\), such that, for any \(\alpha \in \mathcal{S}(T, \mu)\) and any \(v > 0\), the time-dependent matrix \(C^{(v)}\) constructed from \(\alpha\) as in (4.4) and (4.6) is in \(L^\infty(\mathcal{M}_{2h+1-j_0}(\mathbb{R}))\) and satisfies, for all \(t \geq 0\),

\[
\int_t^{t+T} C^{(v)}(s)ds \geq \frac{\xi}{v} T \Id_{2h+1-j_0}.
\]

For this \(\xi > 0\), take \(C \geq 1, \gamma > 0, r > 0\), and \(\mathcal{X}_j \in \mathcal{M}_{1,r_j}(\mathbb{R})\) as in Lemma 4.2. Set \(\mathcal{T} = [\tau_0 - r, \tau_0 + r] \cap \mathbb{R}_+\) and construct \(K = (K_0 \cdots K_h)\) from the \(\mathcal{X}_j, j = j_0, \ldots, h\) as in (4.3). We want to show that, for \(v > 0\) large enough, \(K\) is a \((T/v, \mu/v, \mathcal{T}/v)\)-stabilizer for (4.2), and this will conclude the proof by the conclusion of Step 2.

Note that, by Lemma 4.2, there exists a time \(\sigma > 0\) depending only on \(C\) and \(\gamma\) such that, for every trajectory \(y\) of (4.8) starting in \(B_2 = \{x \in \mathbb{R}^d \mid \|x\| \leq 2\}\) at time 0 lies in \(B_1 = \{x \in \mathbb{R}^d \mid \|x\| \leq 1\}\) for every time larger than \(\sigma\). We claim that, for some \(v > 0\) large enough, for every \(\alpha \in \mathcal{S}(T/v, \mu/v)\), every \(\tau \in L^\infty(\mathcal{T}, \mathcal{T}/v)\) and every initial condition \(y^0 \in C^0([-R/v, 0], B_2),\) with \(R = \sup \mathcal{T}\), the solution \(y\) of (4.5), with \(C^{(v)}\) and \(P^{(v)}\) given by (4.4) and (4.6), stays in \(B_1\) for every time larger than \(2\sigma\). This will show, by linearity, that \(K\) is a \((T/v, \mu/v, \mathcal{T}/v)\)-stabilizer for (4.2).
Assume, by contradiction, that for every \( n \in \mathbb{N}^* \) there exist \( \tau_n \in L^\infty(\mathbb{R}_+, \mathcal{T}/n), y_n^0 \in C^0([-R/n, 0], B_2), \alpha_n \in \mathcal{G}(T/n, \mu/n) \), and \( t_n \in [2\sigma, 4\sigma] \) such that, for every \( n \in \mathbb{N}^* \), the solution \( y_n \) of (4.5), with \( C(n) \) and \( P(n) \) given by (4.4) and (4.6), satisfies

\[
y_n(t_n) \notin B_1.
\]

Up to the extraction of a subsequence, we can suppose that

\[
\lim_{n \to +\infty} t_n = t_* \in [2\sigma, 4\sigma],
\]

\[
\lim_{n \to +\infty} y_n^0(0) = y_*^0 \in B_2,
\]

\[
\lim_{n \to +\infty} C(n) = C_* \in L^\infty(\mathbb{R}_+, M_{2h+1-J_0}(\mathbb{R})) \quad \text{weakly-}*,
\]

\[
\lim_{n \to +\infty} P(n) = P_* \in L^\infty(\mathbb{R}_+, M_{2h+1-J_0}(\mathbb{R})) \quad \text{weakly-}*,
\]

and we also note that \( \tau_n(t) \to 0 \) uniformly on \( t \in \mathbb{R}_+ \) as \( n \to +\infty \). Then, by Lemma A.1, \( y_n \) converges to the solution \( y_* \) of (4.8) associated to \( C_* , P_* \) and with initial condition \( y_*^0 \), uniformly on compact time intervals, and in particular \( y_n(t_n) \to y_*(t_*) \). By [11, Lemma 2.5], we have \( C_* (t) \geq \xi \text{Id}_{2h+1-J_0} \) for almost every \( t \) and, since \( \left\| P_{j\ell}(t) \right\| \leq r\Omega \) for every \( j, \ell \in \{j_0, \ldots, h\} \) and almost every \( t \in \mathbb{R}_+ \), we have, by the lower semicontinuity of the norm of \( L^\infty(\mathbb{R}_+, M_{2h+1-J_0}(\mathbb{R})) \), that \( \left\| P_{j\ell}(t) \right\| \leq r\Omega \) for every \( j, \ell \in \{j_0, \ldots, h\} \) and almost every \( t \in \mathbb{R}_+ \), where \( P_{j\ell} \) is obtained from \( P_* \) by (4.9). Thus we are under the hypotheses of Lemma 4.2, and so our previous discussion shows us that \( y_* \) remains in \( B_1 \) for every time larger than \( \sigma \); by linearity, \( \left\| y_*(t_*) \right\| \leq 1/2 \) since \( t_* \geq 2\sigma \). This contradicts (4.11), establishing the desired result.

\[\]
A natural question is then to study if Theorem 2.5 might not be generalized for any bounded set $\mathcal{T}$ instead of considering only perturbations around $\tau_0$. This is actually not possible, as shown in the following example, where we take $\alpha$ identically equal to one, i.e., the control is completely active the whole time.

**Example 5.1.** Consider the control system

$$\dot{x} = Ax + Bu$$

with

$$A = \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix}, \quad B = \begin{pmatrix} 0 \\ 1 \end{pmatrix}$$

and submitted to the feedback law

$$u(t) = -Kx(t - \tau(t))$$

This control system does not depend on a persistently exciting signal $\alpha$, but, in order to keep the notations we used previously, we shall consider it as a persistently excited system with constants $T = \mu$, so that $\mathcal{S}(T, \mu) = \mathcal{S}(T)$ reduces to the class containing only the constant signal identically equal to one. We want to prove that the conclusion of Theorem 3.1 does not hold for (5.1), that is, we want to show that there exists a bounded interval $T$ for which (5.1) with the feedback (5.2) does not admit a $(T, T, T)$-stabilizer. Obviously, this also implies the non-existence of a $(T, \mu, \mathcal{T})$-stabilizer for every $\mu \in (0, T]$ since such a stabilizer would be in particular a $(T, T, \mathcal{T})$-stabilizer.

We claim that (5.1) with the feedback (5.2) does not admit a $(T, T, [0, 2\pi])$-stabilizer. In order to simplify our analysis, we shall consider only constant-in-time delays in the interval $[0, 2\pi]$, which allow us to apply the techniques of stability analysis for delayed systems presented in [26].

The closed-loop system obtained from (5.1) with the feedback (5.2) and a constant delay $\tau \in [0, 2\pi]$ is

$$\dot{x}(t) = Ax(t) - BKx(t - \tau).$$

According to [26, Proposition 1.6], the stability of (5.3) can be studied through the complex roots $\lambda$ of the characteristic equation

$$\det \left( \lambda \text{Id}_2 - A + BK e^{-\lambda \tau} \right) = 0; \quad (5.4)$$

the origin of (5.3) is exponentially stable if and only if all the roots $\lambda$ of (5.4) satisfy $\Re(\lambda) < 0$, and exponential stability and asymptotic stability are also equivalent in this case.

Writing $K = (k_1 \ k_2)$, the characteristic equation (5.4) is

$$\lambda^2 + k_2 \lambda e^{-\lambda \tau} + 1 + k_1 e^{-\lambda \tau} = 0. \quad (5.5)$$

We now want to show that, for every $K \in \mathcal{M}_{1,2}(\mathbb{R})$, there exists $\tau \in [0, 2\pi]$ such that (5.5) admits a root $\lambda$ with $\Re(\lambda) \geq 0$. As remarked in [26, Theorem 1.15], by the continuity of the real part of the largest eigenvalue with respect to the delay, this study is reduced to the problem of finding a delay $\tau \in [0, 2\pi]$ such that (5.5) admits a root $\lambda$ with $\Re(\lambda) = 0$.

The feedback $K = 0$ obviously does not stabilize the system to the origin, and so we suppose from now on that $k_1$ and $k_2$ are not simultaneously zero. We look for a certain $\tau \in [0, 2\pi]$ and a root $\lambda = i\omega$ of (5.5) with $\omega \in \mathbb{R}$. We thus want $\omega$ to satisfy

$$\begin{cases}
1 - \omega^2 + k_1 \cos(\tau \omega) + k_2 \omega \sin(\tau \omega) = 0, \\
-k_1 \sin(\tau \omega) + k_2 \omega \cos(\tau \omega) = 0.
\end{cases}$$
This is equivalent to

\[
\begin{align*}
\sin \theta &= \frac{k_2 \omega (\omega^2 - 1)}{k_2^2 \omega^2 + k_1^2}, \\
\cos \theta &= \frac{k_1 (\omega^2 - 1)}{k_2^2 \omega^2 + k_1^2}, \\
\theta &= \tau \omega
\end{align*}
\]  

(5.6)

and such a system can only have a solution if \( \sin^2 \theta + \cos^2 \theta = 1 \), which is the case if and only if \( (\omega^2 - 1)^2 = k_2^2 \omega^2 + k_1^2 \). This last equation is a polynomial in \( \omega^2 \) of degree 2, whose solutions can be computed explicitly as

\[
\omega^2 = \frac{1}{2} \left[ 2 + k_2^2 \pm \sqrt{(2 + k_2^2)^2 - 4(1 - k_1^2)} \right].
\]

We consider from now on the solution

\[
\omega = \sqrt{\frac{2 + k_2^2 + \sqrt{(2 + k_2^2)^2 - 4(1 - k_1^2)}}{2}}.
\]

Note that \( \omega \) is well-defined in \( \mathbb{R} \) since \( (2 + k_2^2)^2 > 4(1 - k_1^2) \) for any \( K \in \mathcal{M}_{1,2}(\mathbb{R}) \setminus \{0\} \), and that \( \omega \geq 1 \). With this \( \omega \), we can thus find \( \theta \in [0, 2\pi] \) such that (5.6) is satisfied, and so \( \tau = \theta / \omega \in [0, 2\pi] \) since \( \omega \geq 1 \). Since the constructed \( (\theta, \tau, \omega) \) satisfies (5.6), (5.5) is hence satisfied for \( \tau \) and \( \lambda = i\omega \), and thus (5.3) is not asymptotically stable. Hence (5.1) admits no \( (T, T, [0, 2\pi]) \)-stabilizer. \( \square \)

Note that we could replace \([0, 2\pi]\) in Example 5.1 for any other interval \( \mathcal{T} \subset \mathbb{R}_+ \) with length greater than or equal 2\( \pi \), and so we conclude that (5.1) does not admit a \( (T, \mu, \mathcal{T}) \)-stabilizer if \( \mathcal{T} \) contains an interval with length greater than or equal 2\( \pi \).

The value 2\( \pi \) obtained in these computations comes from the fact that the dynamics given by the matrix \( A \) we chose correspond to rotations around the origin with unitary angular velocity, and 2\( \pi \) is the total time that a solution of \( \dot{x} = Ax \) takes to make a complete turn around the origin. If we choose \( A \) as

\[
A = \begin{pmatrix} 0 & \omega_0 \\ -\omega_0 & 0 \end{pmatrix}
\]

for \( \omega_0 \neq 0 \), then the same computations as in Example 5.1 show that no \( (T, \mu, \mathcal{T}) \)-stabilizer can exist for (5.1) if \( \mathcal{T} \) contains an interval of length at least \( \frac{2\pi}{\omega_0} \). In particular, this gives a link between an upper bound on the maximal length of an interval contained in \( \mathcal{T} \) for which a \( (T, \mu, \mathcal{T}) \)-stabilizer exists and the eigenvalues of \( A \) on the imaginary axis.

This example shows that the fundamental difference in the statement of Theorems 3.1 and 2.5 concerning the choice of the set \( \mathcal{T} \) actually comes from the dynamics of the system itself, and that no improvement of Theorem 2.5 as good as Theorem 3.1 can be obtained.

\section*{Appendix: A Continuity Result for Delayed Systems}

We show here a continuity result of the solution of a delayed system with respect to its parameters, in the spirit of [8, Proposition 21], which is used in the proof of Theorems 3.1 and 2.5. We place ourselves in a more general setting than (2.2), considering the system

\[
\dot{x}(t) = Ax(t) + B(t)x(t - \tau(t)),
\]

(A.1)
Lemma A.1. Let \((\tau_n)_{n \in \mathbb{N}^*}\) be a sequence on \(L^\infty(\mathbb{R}_+,[0,r[)\) such that \(\tau_n(t) \to 0\) as \(n \to +\infty\) uniformly on \(\mathbb{R}_+\). Suppose \((X_0^{(n)})_{n \in \mathbb{N}^*}\) is a sequence of functions in \(C^0([-r,0],\mathbb{R}^d)\) and \((B_n)_{n \in \mathbb{N}^*}\) a bounded sequence on \(L^\infty(\mathbb{R}_+\times \mathcal{M}_d(\mathbb{R}))\) satisfying

1. \(\lim_{n \to +\infty} x_0^{(n)}(0) = x_0^{\star} \) for a certain \(x_0^{\star} \in \mathbb{R}^d\);
2. there exists \(\Lambda > 0\) such that \(\|x_0^{(n)}(t)\| \leq \Lambda\) for all \(n \in \mathbb{N}^*\) and all \(t \in [-r,0]\);
3. \(B_n \xrightarrow{n \to +\infty} B_\star\) weakly-\(\star\) for a certain \(B_\star \in L^\infty(\mathbb{R}_+\times \mathcal{M}_d(\mathbb{R}))\).

Then \(x(t;\tau_n,x_0^{(n)},B_n) \xrightarrow{n \to +\infty} x(t;0,x_0^{\star},B_\star)\), uniformly on compact time intervals in \(\mathbb{R}_+\).

**Proof.** We can extend \(B_\star\) outside \(\mathbb{R}_+\) to the whole real line in such a way that this extension is an element of \(L^\infty(\mathbb{R},\mathcal{M}_d(\mathbb{R}))\). We fix such an extension, so that \(x(\cdot;0,x_0^{\star},B_\star)\) is absolutely continuous in \(\mathbb{R}\) and satisfies (A.1) for almost every \(t \in \mathbb{R}\); note that this is possible since \(x(\cdot;0,x_0^{\star},B_\star)\) is the solution of a non-delayed system. For simplicity, we shall note \(x_n(t) = x(t;\tau_n,x_0^{(n)},B_n)\) and \(x_\star(t) = x(t;0,x_0^{\star},B_\star)\). We also note by \(M\) an upper bound on \(\|B_n\|_{L^\infty(\mathbb{R}_+\times \mathcal{M}_d(\mathbb{R}))}\) and \(r_n = \sup_{t \in \mathbb{R}_+} \tau_n(t)\), and, by the uniform convergence of \(\tau_n\) to 0, we have that \(r_n \to 0\) as \(n \to +\infty\).

Define \(e_n(t) = x_n(t) - x_\star(t)\) for \(t \geq -r\). Then, for \(t \geq 0\), \(e_n\) satisfies

\[
\dot{e}_n(t) = Ae_n(t) + B_n(t)e_n(t-\tau_n(t)) + f_n(t) \tag{A.2}
\]

with \(f_n\) given by \(f_n(t) = B_n(t)(x_\star(t-\tau_n(t)) - x_\star(t)) + (B_n(t) - B_\star(t))x_\star(t)\).

Since \(x_\star\) is continuous, it follows from Lebesgue’s Dominated Convergence Theorem that

\[
\lim_{n \to +\infty} \int_0^t B_n(s)(x_\star(s-\tau_n(s)) - x_\star(s))ds = 0
\]

for every \(t \geq 0\). By the weak-\(\star\) convergence of \((B_n)\), we have that

\[
\lim_{n \to +\infty} \int_0^t (B_n(s) - B_\star(s))x_\star(s)ds = 0,
\]

and so \(f_n\) satisfies

\[
\lim_{n \to +\infty} \int_0^t f_n(s)ds = 0
\]

for every \(t \geq 0\). Letting \(F_n(t) = \int_0^t f_n(s)ds\), this shows that \(F_n(t) \xrightarrow{n \to +\infty} 0\) for every \(t \geq 0\). This limit is uniform on compact time intervals in \(\mathbb{R}_+\). Indeed, let \(T > 0\) and \(X_\star = \sup_{t \in [-T,T]} \|x_\star(t)\|\); we thus see that \(\|f_n(t)\| \leq 2MX_\star\) and so \(\|F_n(t)\| \leq 2MX_\star T\) for every \(t \in [0,T]\). Furthermore, for \(0 \leq t_1 < t_2 \leq T\), we have

\[
\|F_n(t_2) - F_n(t_1)\| \leq \int_{t_1}^{t_2} \|f_n(s)\|ds \leq 2MX_\star (t_2 - t_1),
\]
and hence \((F_n)\) is equicontinuous. Thus, by Arzelà-Ascoli Theorem, the closure of \(\{F_n \mid n \in \mathbb{N}^+\}\) is a compact subset of \(C^0([0, T], \mathbb{R}^d)\) with the topology of the uniform convergence, and so this set has at least one limit point; it has exactly one, for, if it had two distinct limit points, this would contradict the fact that \((F_n(t))_{n \in \mathbb{N}^+}\) tends pointwise to 0, and so the sequence \((F_n)_{n \in \mathbb{N}^+}\) converges uniformly to 0 in \([0, T]\).

Integrating (A.2) from 0 to \(t \geq 0\), we obtain

\[
e_n(t) = e_n(0) + F_n(t) + \int_0^t A e_n(s)ds + \int_0^t B_n(s)e_n(s - \tau_n(s))ds,
\]

which gives us the estimate

\[
\|e_n(t)\| \leq \|e_n(0)\| + \|F_n(t)\| + \int_0^t \|A\| \|e_n(s)\|ds + M\int_0^t \|e_n(s - \tau_n(s))\|ds.
\]

Define

\[
X_{n,t} = \{s \in [0, t] \mid s - \tau_n(s) < 0\}.
\]

This set is measurable and, since \(0 \leq \tau_n(t) \leq r_n\) for all \(t \in \mathbb{R}_+\), we have that \(X_{n,t} \subset [0, r_n]\), so that \(\lambda(X_{n,t}) \leq r_n\) for all \(t \in \mathbb{R}_+\), where \(\lambda\) denotes the Lebesgue measure. Define also

\[
E_n(t) = \sup_{s \in [t-r_n, t]\cap [0,t]} \|e_n(s)\|
\]

and \(M' = \|A\| + M\). From (A.3), we obtain

\[
\|e_n(t)\| \leq \|e_n(0)\| + \|F_n(t)\| + M\int_{X_{n,t}} \|e_n(s - \tau_n(s))\|ds + M' \int_0^t E_n(s)ds,
\]

so that, for \(t \geq 0\),

\[
E_n(t) \leq \phi_n(t) + M' \int_0^t E_n(s)ds,
\]

with \(\phi_n\) given by \(\phi_n(t) = \|e_n(0)\| + \sup_{\sigma \in [t-r_n, t]\cap [0, t]} \left[\|F_n(\sigma)\| + M\int_{X_{n,\sigma}} \|e_n(s - \tau_n(s))\|ds\right]\).

Applying Gronwall’s Lemma, we get

\[
E_n(t) \leq \phi_n(t) + M' \int_0^t \phi_n(s)e^{M'(t-s)} ds
\]

for \(t \geq 0\).

Fix \(T > 0\). Since \(\lim_{n \to +\infty} F_n(t) = 0\) uniformly on \([0, T]\), we have that

\[
\lim_{n \to +\infty} \left[\sup_{\sigma \in [t-r_n, t]\cap [0, t]} \|F_n(\sigma)\|\right] = 0 \quad \text{uniformly on } t \in [0, T].
\]

Moreover, for \(s \in X_{n,\sigma}\), we have that

\[
\|e_n(s - \tau_n(s))\| = \|x_n(s - \tau_n(s)) - x_*(s - \tau_n(s))\| \leq C,
\]

where \(C = \Lambda + \sup_{t \in [-r, 0]} \|x_*(t)\|\), and so

\[
\sup_{\sigma \in [t-r_n, t]\cap [0, t]} \|e_n(s - \tau_n(s))\| ds \leq C r_n \xrightarrow{n \to +\infty} 0
\]

uniformly on \(t \in [0, T]\). Hence \(\phi_n(t) \xrightarrow{n \to +\infty} 0\) uniformly on \([0, T]\), from where we get, together with (A.4), that \(E_n(t) \xrightarrow{n \to +\infty} 0\) uniformly on \([0, T]\). So \(e_n(t) \xrightarrow{n \to +\infty} 0\) uniformly on \([0, T]\), and, since \(T > 0\) is arbitrary, this gives the desired result. ■
B  Appendix: On the Proof of Theorem 2.5

We prove here some of the results that were used in the proof of Theorem 2.5. The first three results, Lemmas B.1, B.2 and B.3, deal with the reduction of Theorem 2.5 to the case where \((A, B)\) is controllable, \(m = 1\) and all the eigenvalues of \(A\) lie on the imaginary axis. We begin by reducing the theorem to the case where \((A, B)\) is controllable.

**Lemma B.1.** It suffices to prove Theorem 2.5 in the case where \((A, B)\) is controllable.

**Proof.** Up to a linear change of variables, \(A\) and \(B\) can be decomposed on the controllable and uncontrollable parts according to Kalman decomposition as

\[
A = \begin{pmatrix} A_1 & A_3 \\ 0 & A_2 \end{pmatrix}, \quad B = \begin{pmatrix} B_1 \\ 0 \end{pmatrix}
\]

with \(A_1 \in \mathcal{M}_{d'}(\mathbb{R})\), \(A_2 \in \mathcal{M}_{d-d'}(\mathbb{R})\), \(B_1 \in \mathcal{M}_{d,m}(\mathbb{R})\), the other matrices having appropriate dimensions, and where \((A_1, B_1)\) is controllable (see, for instance, [29, Theorem 13.1]); since \((A, B)\) is stabilizable, \(A_2\) is Hurwitz. The open-loop system (2.1) can thus be written after the change of variables as

\[
\begin{align*}
\dot{x}_1(t) &= A_1x_1(t) + A_3x_2(t) + \alpha(t)B_1u(t), \\
\dot{x}_2(t) &= A_2x_2(t),
\end{align*}
\]

(B.1)

with \(x_1(t) \in \mathbb{R}^{d'}\), \(x_2(t) \in \mathbb{R}^{d-d'}\), and \(x(t) = (x_1(t)^T \ x_2(t)^T)^T\). Now, suppose the theorem is proved for the controllable case and \(K' \in \mathcal{M}_{m,d}(\mathbb{R})\) is a \((T, \mu, \mathcal{T})\)-stabilizer for \((A_1, B_1)\) for a certain neighborhood \(\mathcal{Y}\) of \(\mathcal{Y}_0\) in \(\mathbb{R}_+\), associated with certain constants \(C_1 \geq 1\), \(\gamma_1 > 0\) as in Definition 2.2. Take \(K = (K' \ 0) \in \mathcal{M}_{m,d}(\mathbb{R})\), so that, with the feedback \(u(t) = -Kx(t - \tau(t))\), (B.1) becomes

\[
\begin{align*}
\dot{x}_1(t) &= A_1x_1(t) - \alpha(t)B_1K'x_1(t - \tau(t)) + A_3x_2(t), \\
\dot{x}_2(t) &= A_2x_2(t).
\end{align*}
\]

(B.2)

Let us note \(r = \sup \mathcal{Y}\). Take \(\alpha \in \mathcal{S}(T, \mu)\), \(\tau \in L_+^{\infty}(\mathbb{R}_+, \mathcal{T})\), and an initial condition \(x_0 \in C^0([-r, 0], \mathbb{R}^d)\), written as \(x_0(t) = (x_{0,1}(t)^T \ x_{0,2}(t)^T)^T\). Note by \(y(t) \in \mathbb{R}^d\) the solution of

\[
\begin{align*}
\dot{y}(t) &= A_1y(t) - \alpha(t)B_1K'y(t - \tau(t)), & t > 0, \\
y(t) &= x_{0,1}(t), & t \in [-r, 0].
\end{align*}
\]

Then, by the hypothesis on \(K'\), we have that

\[
\|y(t)\| \leq C_1 e^{-\mu t} \sup_{s \in [-r, 0]} \|x_{0,1}(s)\|. \tag{B.3}
\]

The result on [13, Section 6.2] allows us to write the solution \(x(t) = (x_1(t)^T \ x_2(t)^T)^T\) of (B.2) associated with \(\alpha\) and \(\tau\) and with initial condition \(x_0\) as

\[
\begin{align*}
x_1(t) &= y(t) + \int_0^t X(t, s)A_3x_2(s)ds, \\
x_2(t) &= e^{A_2t}x_{0,2}(0),
\end{align*}
\]

(B.4)
Lemma B.2. It suffices to prove Theorem 2.5 in the case where \((A, B)\) is controllable and \(m = 1\).

**Proof.** We may suppose \((A, B)\) controllable by Lemma B.1. We suppose the theorem to be proved in the case \(m = 1\) and we prove the general case by induction on \(m\). Suppose the theorem has been proved for \(m - 1\), that is, for every \(d \in \mathbb{N}^*\), for every \(A \in \mathcal{M}_d(\mathbb{R})\) and \(B \in \mathcal{M}_{d,m-1}(\mathbb{R})\) such that \((A, B)\) is a controllable pair and the eigenvalues of \(A\) have non-positive real part, for every \(T, \mu\) with \(T \geq \mu > 0\), and for every \(\tau_0 \geq 0\), there exists a neighborhood \(\mathcal{T}\) of \(\tau_0\) in \(\mathbb{R}_+\) and a \((T, \mu, \mathcal{T})\)-stabilizer for (2.2).

Take \(A \in \mathcal{M}_d(\mathbb{R})\) and \(B \in \mathcal{M}_{d,m}(\mathbb{R})\) such that \((A, B)\) is a controllable pair and the eigenvalues of \(A\) have non-positive real part and fix \(T \geq \mu > 0\) and \(\tau_0 \geq 0\). Note by \(b \in \mathbb{R}^d\) the first column of \(B\); we may suppose, without loss of generality, that \(b \neq 0\), for otherwise the first input does not influence the system and it may thus be excluded, reducing the system to the case with \(m - 1\) inputs. We consider the pair \((A, b)\), which may not be controllable, but can be decomposed according to Kalman decomposition: there exists an invertible \(P \in \mathcal{M}_d(\mathbb{R})\) such that

\[
PAP^{-1} = \begin{pmatrix} A_1 & A_3 \\ 0 & A_2 \end{pmatrix}, \quad Pb = \begin{pmatrix} b_1 \\ 0 \end{pmatrix},
\]
with \( A_1 \in M_{d'}(\mathbb{R}) \), \( b_1 \in \mathbb{R}^d \), all the other matrices have appropriate dimensions, and \((A_1, b_1)\) is controllable. Now, performing the change of variables \( z = Px \) in (2.1), the open-loop system becomes

\[
\dot{z} = \begin{pmatrix} A_1 & A_3 \\ 0 & A_2 \end{pmatrix} z + \alpha(t) \begin{pmatrix} b_1 \\ 0 \end{pmatrix} u
\]  

(B.7)

with \( B_2 \in M_{d' - m-1}(\mathbb{R}) \) and \( B_3 \in M_{d',m-1}(\mathbb{R}) \).

By the controllability of \((A, B)\) and \((A_1, b_1)\), it follows that \((A_2, B_2)\) is also controllable. Now, \( B_2 \in M_{d' - d',m-1}(\mathbb{R}) \), and so, by the induction hypothesis, \((A_2, B_2)\) admits a \((T, \mu, \mathcal{T}_2)\)-stabilizer \( K_2 \in M_{m-1,d'-d'}(\mathbb{R}) \) for a certain neighborhood \( \mathcal{T}_2 \) of \( \tau_0 \) in \( \mathbb{R}_+ \). If Theorem 2.5 is proved in the controllable case with \( m = 1 \), then we can take a \((T, \mu, \mathcal{T}_1)\)-stabilizer \( K_1 \in M_{1,d'}(\mathbb{R}) \) for \((A_1, b_1)\) for a certain neighborhood \( \mathcal{T}_1 \) of \( \tau_0 \) in \( \mathbb{R}_+ \). We claim that \( K \in M_{m,d}(\mathbb{R}) \) given by

\[
K = \begin{pmatrix} K_1 \\ 0 \\ K_2 \end{pmatrix}
\]

is a \((T, \mu, \mathcal{T})\)-stabilizer for \((A, B)\) for the neighborhood \( \mathcal{T} = \mathcal{T}_1 \cap \mathcal{T}_2 \). Indeed, with this feedback, system (B.7) becomes

\[
\dot{z}(t) = \begin{pmatrix} A_1 & A_3 \\ 0 & A_2 \end{pmatrix} z(t) - \alpha(t) \begin{pmatrix} b_1 K_1 \\ 0 \end{pmatrix} \begin{pmatrix} B_1 \\ B_2 \end{pmatrix} z(t) - \tau(t)).
\]

Noting \( z = \left( \begin{array}{c} z_1 \\ z_2 \end{array} \right)^T \) with \( z_1 \in \mathbb{R}^{d'} \) and \( z_2 \in \mathbb{R}^{d-d'} \), we can thus write

\[
\begin{cases}
\dot{z}_1(t) = A_1 z_1(t) - \alpha(t) b_1 K_1 z_1(t - \tau(t)) + A_3 z_2(t) - \alpha(t) B_3 K_2 z_2(t - \tau(t)), \\
\dot{z}_2(t) = A_2 z_2(t) - \alpha(t) B_2 K_2 z_2(t - \tau(t)).
\end{cases}
\]

(B.8)

We denote by \( X(t, s) \) the fundamental matrix solution of \( \dot{x} = A_1 x(t) - \alpha(t) b_1 K_1 x(t - \tau(t)) \); by construction of \( K_1 \) and by [13, Lemma 6.5.3], we can find \( C_0 \geq 1 \) and \( \gamma_0 > 0 \), both independent of \( \alpha \in \mathcal{S}(T, \mu) \) and \( \tau \in L^\infty(\mathbb{R}_+, \mathcal{T}) \), such that

\[
\|X(t, s)\| \leq C_0 e^{-\gamma_0(t-s)}, \quad \forall t \geq s \geq 0.
\]

Note \( r = \sup \mathcal{T} \). Given an initial condition \( \left( \begin{array}{c} z_{0,1}^T \\ z_{0,2}^T \end{array} \right)^T \in C^0([-r, 0], \mathbb{R}^d) \), note by \( y_1 \) and \( y_2 \) the solutions to

\[
\begin{cases}
\dot{y}_1(t) = A_1 y_1(t) - \alpha(t) b_1 K_1 y_1(t - \tau(t)), \\
\dot{y}_2(t) = A_2 y_2(t) - \alpha(t) B_2 K_2 y_2(t - \tau(t)),
\end{cases}
\]

(B.9)

By construction of \( K_1 \) and \( K_2 \), there exist \( C_1, C_2 \geq 1 \) and \( \gamma_1, \gamma_2 > 0 \) such that

\[
\|y_j(t)\| \leq C_j e^{-\gamma_j t} \sup_{s \in [-r, 0]} \|z_{0,j}(s)\|, \quad j = 1, 2.
\]

We can now write the solution of (B.8) in terms of the initial condition \( \left( \begin{array}{c} z_{0,1}^T \\ z_{0,2}^T \end{array} \right)^T \in C^0([-r, 0], \mathbb{R}^d) \) using the variation-of-constants formula in [13, Section 6.2] as

\[
\begin{cases}
z_1(t) = y_1(t) + \int_0^t X(t, s) (A_3 z_2(s) - \alpha(s) B_3 K_2 z_2(s - \tau(s)))ds, \\
z_2(t) = y_2(t).
\end{cases}
\]
It is thus easy to see that
\[
\begin{cases}
\|z_1(t)\| \leq C_1 e^{-\gamma t} \sup_{s \in [-r,0]} \|z_{0,1}(s)\| + C' e^{-\gamma' t} \sup_{s \in [-r,0]} \|z_{0,2}(s)\|, \\
\|z_2(t)\| \leq C_2 e^{-\gamma t} \sup_{s \in [-r,0]} \|z_{0,2}(s)\|
\end{cases}
\]
for certain constants $C' \geq 1$, $\gamma' > 0$, and so $K$ is a $(T, \mu, T)$-stabilizer for (B.7), as we wanted to prove. The result is thus established by induction.

We further reduce our proof of Theorem 2.5 to the case where all the eigenvalues of $A$ lie on the imaginary axis.

**Lemma B.3.** It suffices to prove Theorem 2.5 in the case where $(A, B)$ is controllable, $m = 1$, and $\Re(\lambda) = 0$ for every eigenvalue $\lambda$ of $A$.

**Proof.** We may suppose $(A, B)$ controllable and $m = 1$ by Lemma B.2. Up to a linear change of variables, $A$ and $B$ can be written as
\[
A = \begin{pmatrix} A_1 & A_3 \\ 0 & A_2 \end{pmatrix}, \quad B = \begin{pmatrix} B_1 \\ B_2 \end{pmatrix}
\]
with $A_1 \in M_d'(\mathbb{R})$, $A_2 \in M_{d-d'}(\mathbb{R})$, $B_1 \in \mathbb{R}^{d'}$, the other matrices having appropriate dimensions, and where $A_1$ is Hurwitz and all the eigenvalues of $A_2$ have real part 0. Since $(A, B)$ is controllable, $(A_2, B_2)$ is also controllable. The open-loop system (2.1) can thus be written after the change of variables as
\[
\begin{cases}
\dot{x}_1(t) = A_1 x_1(t) + A_3 x_2(t) + \alpha(t) B_1 u(t), \\
\dot{x}_2(t) = A_2 x_2(t) + \alpha(t) B_2 u(t),
\end{cases}
\]
(B.10)
with $x_1(t) \in \mathbb{R}^{d'}$, $x_2(t) \in \mathbb{R}^{d-d'}$, and $x(t) = (x_1(t)^T \ x_2(t)^T)^T$. Now, suppose the theorem is proved for the case stated above and take $K' \in M_{1,d-d'}(\mathbb{R})$ a $(T, \mu, T)$-stabilizer for $(A_2, B_2)$ for a certain neighborhood $\mathcal{F}$ of $t_0$ in $\mathbb{R}_+$, associated with certain constants $C_2 \geq 1$, $\gamma_2 > 0$ as in Definition 2.2. Take $K = \begin{pmatrix} 0 & K' \end{pmatrix} \in M_{1,d}(\mathbb{R})$, so that, with the feedback $u(t) = -K x(t - \tau(t))$, (B.10) becomes
\[
\begin{cases}
\dot{x}_1(t) = A_1 x_1(t) + A_3 x_2(t) - \alpha(t) B_1 K' x_2(t - \tau(t)), \\
\dot{x}_2(t) = A_2 x_2(t) - \alpha(t) B_2 K' x_2(t - \tau(t)).
\end{cases}
\]
(B.11)
Let us note $r = \sup \mathcal{F}$. Take $\alpha \in \mathcal{S}(T, \mu)$, $\tau \in L^\infty(\mathbb{R}_+, T)$, and an initial condition $x_0 \in C^0([-r,0], \mathbb{R}^d)$, written as $x_0(t) = (x_{0,1}(t)^T \ x_{0,2}(t)^T)^T$. By the hypothesis on $K'$, we have that the solution $x(t) = (x_1(t)^T \ x_2(t)^T)^T$ of (B.11) associated with $\alpha$ and $\tau$ and with initial condition $x_0$ satisfies
\[
\|x_2(t)\| \leq C_2 e^{-\gamma_2 t} \sup_{s \in [-r,0]} \|x_2(s)\|.
\]
Applying the variation-of-constants formula to (B.11) and using an exponential estimate on $\|e^{A_1 t}\|$, it is immediate to verify that $K$ is a $(T, \mu, T)$-stabilizer for $(A, B)$.

Let us now present a proof of Lemma 4.1, which was originally done in [11] and that we recall here for the sake of completeness.
Proof of Lemma 4.1. Up to a linear change of variables in (2.1), we may suppose that 
A is in its real Jordan normal form. A has a unique Jordan block associated with each 
\{-i\phi_j, i\phi_j\}, j = j_0, \ldots, h, for, otherwise, the rank of the matrix \((A - i\phi_j\text{Id}_d \ B)\) would be 
strictly smaller than \(d\), contradicting the Hautus test for controllability. Thus, up to a permutation 
of variables on \(\mathbb{R}^d\), we can write \(A = \text{diag}(J_{r_0}, \omega_1 A^{(1)} + F^C_{r_1}, \ldots, \omega_h A^{(h)} + F^C_{r_h})\), and \(B \in \mathbb{R}^d\) is such that \((A,B)\) is controllable. Now, take \(\tilde{b} \in \mathbb{R}^d\) as \(\tilde{b} = ((b^0)^T \ (b^1)^T \ \ldots \ (b^h)^T)^T\) 
with \(b^0 \) and \(b^j, j = 1, \ldots, h\), as defined in the statement of the lemma. It follows from Hautus 
test for controllability that \((A, \tilde{b})\) is controllable. But all controllable linear control systems 
associated with a pair \((A, B)\) that have in common the eigenvalues of \(A\), counted according to 
their multiplicity, are state-equivalent, since they can be transformed by a linear transformation of 
coordinates into the same system under controller form (see, e.g., [31]), and so \((A,B)\) can be transformed into \((A, \tilde{b})\) by a linear transformation of coordinates, leading to 
the desired result.

Finally, to complete the proof of Theorem 2.5, we prove Lemma 4.2, which gives the uniform 
exponential stability of the limit system considered in the proof of Theorem 2.5.

Proof of Lemma 4.2. We consider the matrices \(P_{j\ell}\) as a perturbations in (4.8), and so we 
consider first the non-perturbed system

\[
\begin{align*}
\dot{y}_0(t) &= J_{r_0} y_0(t) - \sum_{\ell=0}^h [b^0 J_{\ell} \otimes C_{0\ell}(t)] y_\ell(t), \\
\dot{y}_j(t) &= J_{r_j} y_j(t) - \sum_{\ell=0}^h [b^j J_{\ell} \otimes C_{j\ell}(t)] y_\ell(t), \quad j = 1, \ldots, h.
\end{align*}
\]

Let \(\xi > 0\). It has been proved in [11, Theorem 3.2] that, for a given \(\xi > 0\), one can find 
a gain \(K = (K_0 \ K_1 \ \cdots \ K_h)\) and a positive definite matrix \(S \in \mathcal{M}_d(\mathbb{R})\) such that, for 
every symmetric \(C_\ast \in L^\infty(\mathbb{R}_+, \mathcal{M}_{2h+1-j_0}(\mathbb{R}))\) satisfying \(C_\ast(t) \geq \xi \text{Id}_{2h+1-j_0}\) for almost every 
\(t \geq 0\), (B.12) is globally uniformly exponentially stable and \(V(y) = y^T S y\) decreases exponentially 
along all trajectories of (B.12), uniformly with respect to \(C_\ast \in L^\infty(\mathbb{R}_+, \mathcal{M}_{2h+1-j_0}(\mathbb{R}))\) satisfying 
\(C_\ast(t) \geq \xi \text{Id}_{2h+1-j_0}\) almost everywhere; i.e., there exist \(C \geq 1\) and \(\gamma > 0\) such 
that, for every symmetric \(C_\ast \in L^\infty(\mathbb{R}_+, \mathcal{M}_{2h+1-j_0}(\mathbb{R}))\) satisfying \(C_\ast(t) \geq \xi \text{Id}_{2h+1-j_0}\) almost 
everywhere and every solution \(y\) of (B.12), we have

\[
\|y(t)\| \leq Ce^{-2\gamma t}\|y(0)\|.
\]

We denote by \(X(t,s)\) the fundamental matrix solution of (B.12), i.e., for any \(y^0 \in \mathbb{R}^d\), \(y(t) = 
X(t,s)y^0\) is the unique solution to (B.12) with \(y(s) = y^0\). Hence we have the estimate

\[
\|X(t,s)\| \leq Ce^{-2\gamma(t-s)}.
\]

We now turn to the perturbed system (4.8). For a given \(\xi > 0\), we take \(C \geq 1\), \(\gamma > 0\) and 
\(K_j\) as before. For every symmetric matrix \(C_\ast \in L^\infty(\mathbb{R}_+, \mathcal{M}_{2h+1-j_0}(\mathbb{R}))\) satisfying \(C_\ast(t) \geq \xi \text{Id}_{2h+1-j_0}\) almost everywhere, and every \(P_\ast \in L^\infty(\mathbb{R}_+, \mathcal{M}_{2h+1-j_0}(\mathbb{R}))\) satisfying (4.10), we set \(A = \text{diag}(J_{r_0}, J_{r_1}, \ldots, J_{r_h}) \in \mathcal{M}_d(\mathbb{R}),\)

\[
\mathcal{B}(t) = (\tilde{b}^j J_{\ell} \otimes C_{j\ell}(t))_{j_0 \leq j, \ell \leq h}, \quad \mathcal{P}(t) = (\tilde{b}^j J_{\ell} \otimes P_{j\ell}(t))_{j_0 \leq j, \ell \leq h}
\]

with \(\tilde{b}^0 = b^0\). System (4.8) can thus be written under the form

\[
\dot{y}(t) = Ay(t) - \mathcal{B}(t)y(t) - \mathcal{P}(t)y(t)
\]
and, using the fundamental matrix $X$ of (B.12), we can write its solution for a given initial condition $y^0$ as

$$y(t) = X(t, 0)y^0 - \int_0^t X(t, s)\mathcal{P}(s)y(s)ds.$$  

By (4.10), we can write $\|\mathcal{P}(t)\| \leq C'r\Omega$ for a certain constant $C' > 0$, and thus, up to increasing $C$, we have, by (B.13),

$$\|y(t)\| \leq Ce^{-2\gamma\|y^0\|} + Cr\Omega \int_0^t e^{-2\gamma(t-s)} \|y(s)\|ds.$$  

Applying Gronwall’s Lemma to $e^{2\gamma\|y(t)\|}$, we thus obtain

$$\|y(t)\| \leq Ce^{-(2\gamma-Cr\Omega)\|y^0\|}.$$  

We choose $r > 0$ small enough so that $2\gamma - Cr\Omega \geq \gamma$, and so

$$\|y(t)\| \leq Ce^{-\gamma\|y^0\|},$$

which gives us the desired result.

\[\blacksquare\]
