HAL is a multi-disciplinary open access archive for the deposit and dissemination of scientific research documents, whether they are published or not. The documents may come from teaching and research institutions in France or abroad, or from public or private research centers.

L’archive ouverte pluridisciplinaire HAL, est destinée au dépôt et à la diffusion de documents scientifiques de niveau recherche, publiés ou non, émanant des établissements d’enseignement et de recherche français ou étrangers, des laboratoires publics ou privés.
We propose a study of the modes of derivation of higher-order recursion schemes, proving that value trees obtained from schemes using innermost-outermost derivations (IO) are the same as those obtained using unrestricted derivations.

Given that higher-order recursion schemes can be used as a model of functional programs, innermost-outermost derivations policy represents a theoretical viewpoint of call by value evaluation strategy.

1 Introduction

Recursion schemes have been first considered as a model of computation, representing the syntactical aspect of a recursive program [15, 2, 3, 4]. At first, (order-1) schemes were modelling simple recursive programs whose functions only take values as input (and not functions). Since, higher-order versions of recursion schemes [11, 5, 6, 7, 8, 9] have been studied.

More recently, recursion schemes were studied as generators of infinite ranked trees and the focus was on deciding logical properties of these trees [12, 8, 10, 1, 13, 14].

As for programming languages, the question of the evaluation policy has been widely studied. Indeed, different policies result in different evaluation [8, 9, 7]. There are two main evaluation policies for schemes: outermost-innermost derivations (OI) and inner-outermost IO derivations, respectively corresponding to call by need and call by value in programming languages.

Standardization theorem for the lambda-calculus shows that for any scheme, outermost-innermost derivations (OI) lead to the same tree as unrestricted derivation. However, this is not the case for IO derivations. In this paper we prove that the situation is different for schemes. Indeed, we establish that the trees produced using schemes with IO policy are the same as those produced using schemes with OI policy. For a given a scheme of order \( n \), we can use a simplified continuation passing style transformation, to get a new scheme of order \( n + 1 \) in which IO derivations will be the same as OI derivations in the initial scheme (Section 3). Conversely, in order to turn a scheme into another one in which unrestricted derivations lead to the same tree as IO derivations in the initial scheme, we adapt Kobayashi’s [13] recent results on HORS model-checking, to compute some key properties over terms (Section 4.1). Then we embed these properties into a scheme turning it into a self-correcting scheme of the same order of the initial scheme, in which OI and IO derivations produce the same tree (Section 4.2).

2 Preliminaries

Types are defined by the grammar \( \tau ::= o \mid \tau \rightarrow \tau; o \) is called the ground type. Considering that \( \rightarrow \) is associative to the right (i.e. \( \tau_1 \rightarrow (\tau_2 \rightarrow \tau_3) \) can be written \( \tau_1 \rightarrow \tau_2 \rightarrow \tau_3 \)), any type \( \tau \) can be written uniquely as \( \tau_1 \rightarrow ... \rightarrow \tau_k \rightarrow o \). The integer \( k \) is called the arity of \( \tau \). We define the order of a type by \( \text{order}(o) = 0 \) and \( \text{order}(\tau_1 \rightarrow \tau_2) = \max(\text{order}(\tau_1) + 1, \text{order}(\tau_2)) \). For instance \( o \rightarrow o \rightarrow o \rightarrow o \) is a type.
of order 1 and arity 3, \((o \rightarrow o) \rightarrow (o \rightarrow o)\), that can also be written \((o \rightarrow o) \rightarrow o \rightarrow o\) is a type of order 2. Let \(\tau^t \rightarrow \tau'\) be a shortcut for \(\tau \rightarrow \ldots \rightarrow \tau \rightarrow \tau'\).

Let \(\Gamma\) be a finite set of symbols such that to each symbol is associated a type. Let \(\Gamma^\tau\) denote the set of symbols of type \(\tau\). For all type \(\tau\), we define the set of terms of type \(\mathcal{T}^\tau(\Gamma)\) as the smallest set satisfying: \(\Gamma^\tau \subseteq \mathcal{T}^\tau(\Gamma)\) and \(\bigcup_{t \in \mathcal{T}^\tau(\Gamma), t \in \mathcal{T}^\tau(\Gamma)} \subseteq \mathcal{T}^\tau(\Gamma)\). If a term \(t\) is in \(\mathcal{T}^\tau(\Gamma)\), we say that \(t\) has type \(\tau\). We shall write \(\mathcal{T}(\Gamma)\) as the set of terms of any type, and \(t : \tau\) if \(t\) has type \(\tau\). The arity of a term \(t\), \(\text{arity}(t)\), is the type of its head. Remarking that any term \(t\) can be uniquely written as \(t = \alpha t_1...t_k\) with \(\alpha \in \Gamma\). We say that \(\alpha\) is the head of the term \(t\). For instance, let \(\Gamma = \{F : (o \rightarrow o) \rightarrow o \rightarrow o, G : o \rightarrow o \rightarrow o, H : (o \rightarrow o), a : o\}\), \(F\) and \(G\) are terms of type \(o \rightarrow o\); \(F(G a) (H (H a))\) is a term of type \(o\); \(F\) a is not a term since \(F\) is expecting a first argument of type \(o \rightarrow o\) while a has type \(o\).

Let \(t : \tau, t' : \tau'\) be two terms, \(x : \tau'\) a symbol of type \(\tau'\), then we write \(t[t[x \leftarrow t'] : \tau\) the term obtained by substituting all occurrences of \(x\) by \(t'\) in the term \(t\). A \(t\)-context is a term \(C[\bullet^\tau] \in \mathcal{T}(\Gamma \uplus \{\bullet^\tau : \tau\})\) containing exactly one occurrence of \(\bullet^\tau\); it can be seen as an application turning a term into another, such that for all \(t : \tau, C[t] = C[\bullet^\tau][\bullet^\tau \leftarrow t]\). In general we will only talk about ground type context where \(\tau = o\) and we will omit to specify the type when it is clear. For instance, if \(C[\bullet] = F \bullet (H (H a))\) and \(t' = G a\) then \(C[t'] = F (G a) (H (H a))\).

Let \(\Sigma\) be a set of symbols of order at most 1 (i.e. each symbols has type \(o\) or \(o \rightarrow \ldots \rightarrow o\)) and \(\bot : o\) be a fresh symbol. A tree \(t\) over \(\Sigma \uplus \bot\) is a mapping \(t : \text{dom}^t \rightarrow \Sigma \uplus \bot\), where \(\text{dom}^t\) is a prefix-closed subset of \(\{0, ..., m\}^*\) such that if \(u \in \text{dom}^t\) and \(t(u) = a\) then \(\{j \mid u_j \in \text{dom}^t\} = \{0, ..., \text{arity}(a)\}\). Note that there is a direct bijection between ground terms of \(\mathcal{T}(\Sigma \uplus \bot)\) and finite trees: hence we will freely allow ourselves to treat ground terms over \(\Sigma \uplus \bot\) as trees. We define the partial order \(\subseteq\) over trees as the smallest relation satisfying \(\bot \subseteq t\) and \(t \subseteq t\) for any tree \(t\), and \(a t_1...t_k \subseteq a t'_1...t'_k\) iff \(t_i \subseteq t'_i\). Given a (possibly infinite) sequence of trees \(t_0, t_1, t_2, ...\) such that \(t_i \subseteq t_{i+1}\) for all \(i\), one can prove that the set of all \(t_i\) has a supremum which is called the limit tree of the sequence.

A higher order recursion scheme (HORS) \(G = \langle \forall, \Sigma, \mathcal{N}, \mathcal{R}, S \rangle\) is a tuple such that: \(\forall\) is a finite set of typed symbols called variables; \(\Sigma\) is a finite set of typed symbols of order at most 1, called the set of terminals; \(\mathcal{N}\) is a finite set of typed symbols called set of non-terminals; \(\mathcal{R}\) is a set of rewrite rules, one per non terminal \(F : \tau_1 \rightarrow \ldots \rightarrow \tau_k \rightarrow o \in \mathcal{N}\), of the form \(F x_1 ... x_k \rightarrow e\) with \(e : o \in \mathcal{T}(\Sigma \uplus \mathcal{N} \uplus \{x_1, ..., x_k\})\); \(S \in \mathcal{N}\) is the initial non-terminal.

We define the rewriting relation \(\rightarrow_G \in \mathcal{T}(\Sigma \uplus \mathcal{N})^2\) (or just \(\rightarrow\) when \(G\) is clear) as \(t \rightarrow_G t'\) iff there exists a context \(C[\bullet]\), a rewrite rule \(F x_1 ... x_k \rightarrow e\), and a term \(F t_1 ... t_k : o\) such that \(t = C[F t_1...t_k]\) and \(t' = C[e_{[t_1=t_1}...[t_k=t_k]}\). We call \(F t_1 ... t_k : o\) a redex. Finally we define \(\rightarrow_G^+\) as the reflexive and transitive closure of \(\rightarrow_G\).

We define inductively the \(\bot\)-transformation \((\cdot)^\bot : \mathcal{T}(\mathcal{N} \uplus \Sigma)^0 \rightarrow \mathcal{T}(\mathcal{N} \uplus \{\bot : o\})^0\) as \((F t_1 ... t_k)^\bot = \bot \rightarrow \forall F \in \mathcal{N}\) and \((a t_1 ... t_k)^\bot = a t_1^\bot...t_k^\bot\) for all \(a \in \Sigma\). We define a derivation, as a possibly infinite sequence of terms linked by the rewrite relation. Let \(t_0 = S \rightarrow_G t_1 \rightarrow_G t_2 \rightarrow_G \ldots\) be a derivation, then one can check that \((t_0)^\bot \subseteq (t_1)^\bot \subseteq (t_2)^\bot \subseteq \ldots\), hence it admits a limit. One can prove that the set of all such limit trees has a greatest element which we denote \(\|G\|\) and refer to as the value tree of \(G\). Note that \(\|G\|\) is the supremum of \(\{t^\bot \mid S \rightarrow^* t\}\). Given a term \(t : o\), we denote by \(G_t\) the scheme obtained by transforming \(G\) such that it starts derivations with the term \(t\), formally, \(G_t = \langle \forall, \Sigma, \mathcal{N} \uplus \{S\}, \mathcal{R} \uplus \{S' \rightarrow t\}, S' \rangle\). One can prove that if \(t \rightarrow t'\) then \(\|G_t\| = \|G_{t'}\|\).

Example. Let \(G = \langle \forall, \Sigma, \mathcal{N}, \mathcal{R}, S \rangle\) be the scheme such that: \(\forall = \{x : o, \phi : o \rightarrow o, \psi : (o \rightarrow o) \rightarrow o \rightarrow o\}\), \(\Sigma = \{a : o^3 \rightarrow o, b : o \rightarrow o \rightarrow o, c : o\}\), \(\mathcal{N} = \{F : ((o \rightarrow o) \rightarrow o \rightarrow o) \rightarrow (o \rightarrow o) \rightarrow o \rightarrow o, H : (o \rightarrow \)
We now put constraints on the derivations we allow. If there are no constraints, then we say that the value tree of $G$ is the maximum of the limit trees of unrestricted derivations. We define the evaluation tree $\Delta$ to each non terminal, that will be required to rewrite it (hence the types are changed). We feed this argument to the outermost non terminal, and duplicate it to subterms only if the head of the term is a terminal. Hence all derivations will be IO-derivations.

**Evaluation Policies**

We now put constraints on the derivations we allow. If there are no constraints, then we say that the derivations are unrestricted and we let $\text{Acc}^G = \{ t : o \mid S \rightarrow^* t \}$ be the set of accessible terms using unrestricted derivations. Given a rewriting $t \rightarrow t'$ such that $t = C[F \, s_1 \ldots s_k]$ and $t' = C[e[\forall j x_j \rightarrow s_j]]$ with $F \, s_1 \ldots s_k \rightarrow e \in \mathcal{R}$.

- We say that $t \rightarrow t'$ is an outermost-innermost (OI) rewriting (written $t \rightarrow_{OI} t'$) there is no redex containing the occurrence of $\bullet$ as a subterm of $C[\bullet]$.
- We say that $t \rightarrow t'$ is an innermost-outermost (IO) rewriting (written $t \rightarrow_{IO} t'$), if for all $j$ there is no redex as a subterm of $s_j$.

Let $\text{Acc}^G_{OI} = \{ t : o \mid S \rightarrow^*_O t \}$ be the set of accessible terms using OI derivations and $\text{Acc}^G_{IO} = \{ t : o \mid S \rightarrow^*_I t \}$ be the set of accessible terms using IO derivations. There exists a supremum of $\text{Acc}^G_{OI}$ (resp. $\text{Acc}^G_{IO}$) which is the maximum of the limit trees of OI derivations resp. IO derivations. We write it $\|G\|_O I$ (resp. $\|G\|_I O$). For all recursive scheme $G$, $(\text{Acc}^G)^\perp = (\text{Acc}^G)^\perp_{OI}$, in particular $\|G\|_O I = \|G\|$. But $\|G\|_I O \subseteq \|G\|$ and in general, the equality does not hold (see the example is the next section).

### 3 From OI to IO

Fix a recursion scheme $G = (\mathcal{V}, \Sigma, \mathcal{N}, \mathcal{R}, S)$. Our goal is to define another scheme $\overline{G} = (\overline{\mathcal{V}}, \overline{\Sigma}, \overline{\mathcal{N}}, \overline{\mathcal{R}}, I)$ such that $\|\overline{G}\|_I O = \|G\|$. The idea is to add an extra argument ($\Delta$) to each non terminal, that will be required to rewrite it (hence the types are changed). We feed this argument to the outermost non terminal, and duplicate it to subterms only if the head of the term is a terminal. Hence all derivations will be IO-derivations.

We define the transformation over types by $\overline{\sigma} = o \rightarrow o$, and $\overline{\tau_1 \rightarrow \tau_2} = \overline{\tau_1} \rightarrow \overline{\tau_2}$. In particular, if $\tau_1 \rightarrow \ldots \rightarrow \tau_k \rightarrow o$ then $\overline{\tau} = \overline{\tau_1} \rightarrow \ldots \rightarrow \overline{\tau_k} \rightarrow o \rightarrow o$. Note that for all $\tau$, order($\overline{\tau}$) = order($\tau$) + 1.
For all $x : \tau \in \mathcal{V}$ we define $\vec{x} : \tau$ as a fresh variable. Let $ar_{\text{max}}$ be the maximum arity of terminals, we define $\eta_1, \ldots, \eta_{\text{arity}_{\text{max}}}: o \rightarrow o$ and $\delta : o$ as fresh variables, and we let $\mathcal{V} = \{ \vec{x} : \tau \mid x \in \mathcal{V} \} \cup \{ \eta_1, \ldots, \eta_{ar_{\text{max}}} \} \cup \{ \delta : o \}$. Note that $\delta$ is the only variable of type $o$. For all $a : \tau \in \Sigma$ define $\vec{a} : \tau$ as a fresh non-terminal and for all $F : \tau \in \mathcal{N}$ define $\vec{F} : \tau$ as a fresh non-terminal. Let $\mathcal{N} = \{ \vec{a} : \tau \mid a \in \Sigma \} \cup \{ \vec{F} : \tau \mid F \in \mathcal{N} \} \cup \{ \Delta : o, I : o \}$. Note that $I$ and $\Delta$ are the only symbols in $\mathcal{N}$ of type $o$.

Let $t : \tau \in \mathcal{F}(\mathcal{V} \cup \Sigma \cup \mathcal{N})$, we define inductively the term $\vec{t} : \tau \in \mathcal{F}(\mathcal{V} \cup \Sigma \cup \mathcal{N})$: If $t = x \in \mathcal{V}$ (resp. $t = a \in \Sigma$), we let $\vec{t} = \vec{x} \in \mathcal{V}$ (resp. $\vec{t} = \vec{a} \in \Sigma$). If $t = \mathcal{N}$, then $\vec{t} = \vec{t}_1 \mathcal{N}_2$.

Let $a \in \Sigma$ of arity $k$, we define the rule $\vec{a}_1 \ldots \vec{a}_n \delta \rightarrow \vec{t}$ and we define inductively the term $\vec{t}$.

**Example.** Let $G = (\mathcal{V}, \Sigma, \mathcal{N}, \mathcal{R}, S)$ be the order-1 recursion scheme with $\Sigma = \{ a, c : o \}$, $\mathcal{N} = \{ S : o, F : o \rightarrow o, H : o \rightarrow o \}$, $\mathcal{V} = \{ x, y : o \}$, and the following rewrite rules:

$$
S \rightarrow F (H a) \quad F x y \rightarrow y \quad H x \rightarrow H (H x)
$$

Then we have $\|G\|_{\text{IO}} = c$ while $\|G\|_{\text{IO}} = \bot$ (indeed, the only IO derivation is the following $S \rightarrow F (H a) \rightarrow F (H (H a)) \rightarrow \cdots$). The order-2 recursion scheme $\overline{G} = (\overline{\mathcal{V}}, \Sigma, \overline{\mathcal{N}}, \overline{\mathcal{R}}, \overline{S})$ is given by $\overline{\mathcal{N}} = \{ \Delta : o, \overline{\mathcal{N}} \rightarrow \overline{\mathcal{N}} \}$, $\overline{\mathcal{V}} = \{ \delta : o, \overline{x}, \overline{y} : o \}$ and the following rewrite rules:

$$
\overline{I} \rightarrow \overline{\delta} \Delta \\
\overline{H} \overline{x} \overline{y} \rightarrow \overline{H} (H \overline{x}) \Delta \\
\overline{\tau} \delta \rightarrow \overline{c} \\
\overline{\alpha} \delta \rightarrow \overline{a}
$$

Note that in the term $F (H \overline{a}) \overline{\tau} \delta$, the subterm $H \overline{a}$ is no longer a redex since it lacks its last argument, hence it cannot be rewritten. The only IO derivation is the following $\overline{I} \rightarrow \overline{\delta} \Delta \rightarrow F (H \overline{a}) \overline{\tau} \Delta \rightarrow \overline{H} \overline{x} \overline{y} \delta \rightarrow \overline{y} \Delta \rightarrow \overline{\alpha} \delta \rightarrow \overline{a}$.

**Lemma 1.** Any derivation of $\overline{G}$ is in fact an OI and an IO derivation. Hence that $\|\overline{G}\|_{\text{IO}} = \|\overline{G}\|$.

**Proof (Sketch).** The main idea is that the only redexes will be the last argument of the head non-terminal. The scheme is constructed so that $\overline{H}$ remains only on the outermost non-terminals, that is why any derivation is an OI derivation. Furthermore, we have that if $t = \overline{t}_1 \ldots \overline{t}_n \Delta$ is a redex, then none of the $\overline{t}_i$ contains $\Delta$, therefore they do not contain any redex, hence $\overline{t}_i$ is an innermost redex.

Note that OI derivations in $\overline{G}$ acts like OI derivations in $G$, hence $\|G\| = \|\overline{G}\|$.

**Theorem 2 (OI vs IO).** Let $G$ be an order-$n$ scheme. Then one can construct an order-$(n+1)$ scheme $\overline{G}$ such that $\|G\| = \|\overline{G}\|_{\text{IO}}$.

## 4 From IO to OI

The main difference of this section is to transform the scheme $G$ into a scheme $G''$ such that $\|G''\| = \|G\|_{\text{IO}}$. The main difference between IO and OI derivations is that some redex would lead to $\bot$ in IO derivation while OI derivations could be more productive. For example take $F : o \rightarrow o$ such that $F x \rightarrow c$, and $H : o$ such that $H \rightarrow a H$, with $a : o \rightarrow o$ and $c : o$ being terminal symbols. The term $F H$ has a unique OI derivation, $F H \rightarrow a F c$, is finite and it leads to the value tree associated. On the other hand, the (unique) IO derivation is the following $F H \rightarrow F (a H) \rightarrow F (a (a H)) \rightarrow \cdots$ which leads to the tree $\bot$.

The idea of the transformation is to compute a tool (based on a type system) that decides if a redex would produce $\bot$ with IO derivations (Section 4.1); then we embed it into $G$ and force any such redex to produce $\bot$ even with unrestricted derivations (Section 4.2).
4.1 The Type System

Given a term \( t : \tau \in \mathcal{T}(\Sigma \cup \mathcal{N}) \), we define the two following properties on \( t \): \( \mathcal{P}_\bot(t) = \text{“The term } t \text{ has type } \bot \text{ and its associated IO valuation tree is } \bot \text{”} \), and \( \mathcal{P}_\omega(t) = \text{“the term } t \text{ has not necessarily ground type, it contains a redex } r \text{ such that any IO derivation from } r \text{ producing it’s IO valuation tree is infinite”} \). Note that \( \mathcal{P}_\omega(t) \) is equivalent to “the term \( t \) contains a redex \( r \) such that \( \|G_r\|_{\text{IO}} \) is either infinite or contains \( \bot \)”.

In this section we describe a type system, inspired from the work of Kobayashi [13], that characterises if a term verifies these properties.

Let \( Q \) be the set \( \{q_\bot, q_\omega\} \). Given a type \( \tau \), we define inductively the sets \((\tau)_{\text{atom}}\) and \((\tau)^\wedge\) called respectively set of atomic mappings and set of conjunctive mappings:

\[
(\tau)_{\text{atom}} = Q, \quad (\tau)^\wedge = \{\wedge \{\theta_1, \ldots, \theta_i\} | \theta_1, \ldots, \theta_i \in Q\}, \quad (\tau_1 \rightarrow \tau_2)_{\text{atom}} = \{q_\omega\} \cup \{(\tau_1)^\wedge \rightarrow (\tau_2)_{\text{atom}}\}
\]

We will usually use the letter \( \theta \) to represents atomic mappings, and the letter \( \sigma \) to represent conjunctive mappings. Given a conjunctive mapping \( \sigma \) (resp. an atomic mapping \( \theta \)) and a type \( \tau \), we write \( \sigma : \tau \) (resp. \( \theta : \alpha \)) the relation \( \sigma \in (\tau)^\wedge \) (resp. \( \theta \in (\tau)_{\text{atom}}\)). For the sake of simplicity, we identify the atomic mapping \( \theta \) with the conjunctive mapping \( \wedge \{\theta\}\).

Given a term \( t \) and a conjunctive mapping \( \sigma \), we define a judgment as a tuple \( \Theta \vdash t : \sigma \), pronounce “from the environment \( \Theta \), one can prove that \( t \) matches the conjunctive mapping \( \sigma \)”, where the environment \( \Theta \) is a partial mapping from \( \mathcal{T}(\Sigma \cup \mathcal{N}) \) to conjunctive mapping. Given an environment \( \Theta, \alpha \in \mathcal{V} \cup \mathcal{N} \) and a conjunctive mapping \( \sigma \), we define the environment \( \Theta' = \Theta, \alpha : \sigma \) as \( \text{Dom}(\Theta') = \text{Dom}(\Theta) \cup \{\alpha\} \) and \( \Theta'(\alpha) = \sigma \) if \( \alpha \notin \text{Dom}(\Theta) \), \( \Theta'(\alpha) = \sigma \land \Theta(\alpha) \) otherwise, and \( \Theta'(\beta) = \Theta(\beta) \) if \( \beta \neq \alpha \).

We define the following judgement rules:

\[
\frac{\Theta \vdash t : \theta_1 \ldots \theta_n}{\Theta \vdash t : \wedge \{\theta_1, \ldots, \theta_n\}} \quad \text{(Set)} \quad \Theta, \alpha \vdash \wedge \{\theta_1, \ldots, \theta_n\} : \alpha \vdash \theta_i \quad \text{(At) (for all i)}
\]

\[
\frac{\Theta \vdash a : \sigma_1 \rightarrow \ldots \rightarrow \sigma_{i_{\text{arity}(a)}} : q_\omega}{\Theta \vdash a : \sigma_1 \rightarrow \ldots \rightarrow \sigma_{i_{\text{arity}(a)}} : q_\omega} \quad \text{(Set)} \quad \text{for } a \in \Sigma \text{ and } \exists j \sigma_j = q_\omega
\]

\[
\frac{\Theta \vdash t_1 : \sigma \rightarrow \theta \quad \Theta \vdash t_2 : \sigma}{\Theta \vdash t_1 \circ t_2 : \sigma} \quad \text{(App)} \quad \Theta \vdash t : \tau_1 \rightarrow \tau_2 \quad \Theta \vdash t : q_\omega \rightarrow q_\omega \quad \Theta \vdash t_1 : q_\omega \rightarrow q_\omega \quad \Theta \vdash t_2 : q_\omega \rightarrow q_\omega \quad \text{(Set)} \quad \text{if } \tau_1 \rightarrow \tau_2 \quad \text{if } t : \tau_1 \rightarrow \tau_2
\]

Remark that there is no rules that directly involves \( q_\bot \), but it does not mean that no term matches \( q_\bot \), since it can appear in \( \Theta \). Rules like \( \text{(At)} \) or \( \text{(App)} \) may be used to state that a term matches \( q_\bot \).

We say that \( (G, t) \) matches the conjunctive mapping \( \sigma \) written \( \vdash (G, t) : \sigma \) if there exists an environment \( \Theta \), called a witness environment of \( (G, t) \), such that (1) \( \text{Dom}(\Theta) = \mathcal{N} \), (2) \( \forall F : \tau \in \mathcal{N} \Theta(F) \vdash t \), (3) if \( F x_1 \ldots x_k \rightarrow e \in \mathcal{R} \) and \( \Theta \vdash F : \sigma_1 \rightarrow \ldots \rightarrow \sigma_{i_{\text{arity}(a)}} \rightarrow q \) then either there exists \( j \) such that \( q \in \sigma_j \), or \( i = k \) and \( \Theta, x_1 \circ \sigma_1, \ldots, x_k \circ \sigma_k \vdash e \rightarrow q \), (4) \( \Theta \vdash t : \sigma \).

The following two results state that this type system matches the properties \( \mathcal{P}_\bot \) and \( \mathcal{P}_\omega \) and furthermore we can construct a universal environment, \( \Theta^* \), that can correctly judge any term.

**Theorem 3** (Soundness and Completeness). Let \( G \) be an HORS, and \( t \) be term (of any type), \( \vdash (G, t) : q_\omega \) (resp. \( \vdash (G, t) : q_\bot \)) if and only if \( \mathcal{P}_\omega(t) \) (resp. \( \mathcal{P}_\bot(t) \)) holds.

**Proposition 4** (Universal Witness). There exists an environment \( \Theta^* \) such that for all term \( t \), the judgment \( \vdash (G, t) : \sigma \) holds if and only if \( \Theta^* \vdash t : \sigma \).
Proof (Sketch). To compute \( \Theta^* \), we start with an environment \( \Theta_0 \) satisfying Properties (1) and (2) (\( \text{Dom}(\Theta_0) = \mathcal{N} \) and \( \forall F : \tau \in \mathcal{N} \Theta_0(F) : \tau \)) that is able to judge any term \( t : \tau \) with any conjunctive mapping \( \sigma \vdash \tau \).

Then let \( \mathcal{F} \) be the mapping from the set of environments to itself, such that for all \( F : \tau_1 \rightarrow \ldots \rightarrow \tau_k \rightarrow o \in \mathcal{N} \), if \( F x_1 \ldots x_k \rightarrow e \in \mathcal{R} \) then,

\[
\mathcal{F}(\Theta)(F) = \{ \sigma_1 \rightarrow \ldots \rightarrow \sigma_k \rightarrow q \mid q \in Q \land \forall i \sigma_i : \tau_i \land \Theta, x_1 \triangleright \sigma_1, \ldots, x_k \triangleright \sigma_k \vdash e : q \} \\
\cup \{ \sigma_1 \rightarrow \ldots \rightarrow \sigma_i \leq \kappa \rightarrow q_{\infty} \mid \forall i \sigma_i : \tau_i \land \exists j q_{\infty} \in \sigma_j \} \\
\cup \{ \sigma_1 \rightarrow \ldots \rightarrow \sigma_{\kappa} \rightarrow q_{\infty} \mid \forall i \sigma_i : \tau_i \land \exists j q_{\infty} \in \sigma_j \}.
\]

We iterate \( \mathcal{F} \) until we reach a fixpoint. The environment we get is \( \Theta^* \), it verifies properties (1) (2) and (3). Furthermore we can show that this is the maximum of all environment satisfying these properties, i.e. if \( \vdash (G, t) \triangleright \sigma \) then \( \Theta^* \vdash t \triangleright \sigma \).

4.2 Self-Correcting Scheme

For all term \( t : \tau \in \mathcal{F}(\Sigma \uplus \mathcal{N}) \), we define \([t] \in (\tau)^{\wedge} \), called the semantics of \( t \), as the conjunction of all atomic mappings \( \sigma \) such that \( \Theta^* \vdash t \triangleright \sigma \) (recall that \( \Theta^* \) is the environment of Proposition \( \mathcal{F} \)). In particular \( \mathcal{F}(\Sigma \uplus \mathcal{N}) \) holds if and only if \( q_{\infty} \in \{ [t] \} \) holds if and only if \( q_{\infty} \in \{ [t] \} \). Given two terms \( t_1 : \tau_1 \rightarrow \tau_2 \) and \( t_2 : \tau_2 \rightarrow \tau_3 \) the only rules we can apply to judge \( \Theta^* \vdash t_1 t_2 \triangleright \sigma \) are \((\text{App}), (q_{\infty} \rightarrow q_{\infty} I)\) and \((q_{\infty} I)\). We see that \( \Theta \) only depends on which atomic mappings are matched by \( t_1 \) and \( t_2 \). In other words \([t_1 t_2] \) only depends on \([t_1]\) and \([t_2]\), we write \([t_1][t_2] = [t_1 t_2]\).

In this section, given a scheme \( G = (\mathcal{V}, \Sigma, \mathcal{N}, \mathcal{R}, S) \), we transform it into \( G' = (\mathcal{V}', \Sigma, \mathcal{N}', \mathcal{R}', S) \) which is basically the same scheme except that while it is producing an IO derivation, it evaluates \([t']\) for any subterm \( t' \) of the current term and label \( t' \) with \([t']\). Note that if \( t \rightarrow t_0 t_1 \) then \([t] = [t']\). Since we cannot syntactically label terms, we will label all symbols by the semantics of their arguments, e.g. if we want to label \( F t_1 \ldots t_k \), we will label \( F \) with the \( k \)-tuple \([t_1], \ldots, [t_k]\).

A problem may appear if some of the arguments are not fully applied, for example imagine we want to label \( F H \) with \( H : o \rightarrow o \). We will label \( F \) with \([H]\), but since \( H \) has no argument we do not know how to label it. The problem is that we cannot wait to label it because once a non-terminal is created, the derivation does not depend explicitly on it. The solution is to create one copy of \( H \) per possible semantics for its argument (here there are four of them: \( \land\{\}\), \( \land\{q_1\} \), \( \land\{q_{\infty}\} \), \( \land\{q_{\infty} \rightarrow q_1\} \)). This means that \([F[H]]\) would not have the same type as \( F \): \( F \) has type \((o \rightarrow o) \rightarrow o \), but \([F[H]]\) will have type \((o \rightarrow o)^4 \rightarrow o \). Hence, \( F H \) will be labelled the following way: \( F[H] \land\{\} H \land\{q_1\} H \land\{q_{\infty}\} H \land\{q_{\infty} \rightarrow q_1\} \). Note that even if \( F \) has 4 arguments, it only has to be labelled with one semantics since all four arguments represent different labelling of the same term. We now formalize these notions.

Let us generalize the notion of semantics to deals with terms containing some variables. Given an environment on the variables \( \Theta^\tau \) such that \( \text{Dom}(\Theta^\tau) \subseteq \mathcal{V} \) and if \( x : \tau \) then \( \Theta^\tau(x) : \tau \), and given a term \( t : \tau \in \mathcal{F}(\Sigma \uplus \mathcal{N} \uplus \text{Dom}(\Theta^\tau)) \), we define \([t]_{\Theta^\tau} \in (\tau)^{\wedge} \), as the conjunction of all atomic mappings \( \sigma \) such that \( \Theta^\tau \vdash t \triangleright \sigma \). Given two terms \( t_1 : \tau_1 \rightarrow \tau_2 \) and \( t_2 : \tau_2 \rightarrow \tau_3 \) we still have that \([t_1 t_2]_{\Theta^\tau} \) only depends on \([t_1]_{\Theta^\tau}\) and \([t_2]_{\Theta^\tau}\).

To a type \( \tau = \tau_1 \rightarrow \ldots \rightarrow \tau_k \rightarrow o \) we associate the integer \([\tau] = \text{Card}\{\langle \sigma_1, \ldots, \sigma_k \rangle \mid \forall i \sigma_i \in (\tau)^{\wedge}\}\) and a complete ordering of \( \{\langle \sigma_1, \ldots, \sigma_k \rangle \mid \forall i \sigma_i \in (\tau)^{\wedge}\} \) denoted \( \tilde{\sigma}_1^\tau, \tilde{\sigma}_2^\tau, \ldots, \tilde{\sigma}_k^\tau \). We define inductively the type \( \tau^+ = (\tau^+_1)[\tilde{\tau}_1] \rightarrow \ldots \rightarrow (\tau^+_k)[\tilde{\tau}_k] \rightarrow o \).
We have shown that value trees obtained from schemes using innermost-outermost derivations (IO) are
unavoidable. We also create an order-
the same as those obtained using unrestricted derivations. More precisely, given an order-
variable $t_0$ such that $\mathcal{G}(\Theta^\mathcal{V}) \subseteq \mathcal{V}$ contains all variables in $t$, we define inductively the term $t^{+_{\Theta^\mathcal{V}}} : t' \in \mathcal{V} (\mathcal{V} \cup \Sigma \cup \mathcal{N})$ for all $\Theta^\mathcal{V}$. If $t = F \in \mathcal{N}$ (resp. $t = x \in \mathcal{V}$), $t^{+_{\Theta^\mathcal{V}}} = F^{+_{\Theta^\mathcal{V}}}$ (resp. $t^{+_{\Theta^\mathcal{V}}} = x^{+_{\Theta^\mathcal{V}}}$). If $t = a \in \Sigma$, $t^{+_{\Theta^\mathcal{V}}} = a$. Finally consider the case where $t = t_0 t_1 t_2$ with $t_0 : t' \rightarrow t$ and $t_2 : t'$. Let $\sigma = (\sigma_0, \sigma_1, \sigma_2)$. Remark that $t^{+_{\Theta^\mathcal{V}}} \sigma_1 \sigma_2 : (t'^{+_{\Theta^\mathcal{V}}})[t'] \rightarrow t'^{+_{\Theta^\mathcal{V}}}$. We define $(t_0 t_1 t_2)^{+_{\Theta^\mathcal{V}}} : t_0^{+_{\Theta^\mathcal{V}}} \sigma_1 \sigma_2 t_1^{+_{\Theta^\mathcal{V}}} \tau \sigma \tau t_2^{+_{\Theta^\mathcal{V}}} \tau'$. Note that since this transformation is only duplicating and annotating, given a term $t^{+_{\Theta^\mathcal{V}}} \sigma_1 \sigma_2 \sigma_3$ we can uniquely find the unique term $t$ associated to it.

Let $F : t_1 \rightarrow \ldots \rightarrow t_k \rightarrow o \in \mathcal{N}$, $\Theta^\mathcal{V} = x_1 \oplus x_2 \oplus \ldots \oplus x_k \oplus \sigma_0$. If $F x_1 \ldots x_k \rightarrow e \in \mathcal{R}$, we define in $\mathcal{R}$ the rule $F^{+_{\Theta^\mathcal{V}}} \sigma_1 \ldots \sigma_k \sigma_0 x_1^{+_{\Theta^\mathcal{V}}} \ldots x_k^{+_{\Theta^\mathcal{V}}} \rightarrow e^{+_{\Theta^\mathcal{V}}}$. Finally, recall that $\mathcal{G}' = (\mathcal{V}', \sigma', \mathcal{R}', \mathcal{S})$.

The following theorem states that $\mathcal{G}'$ is just a labeling version of $\mathcal{G}$ and that it acts the same.

**Theorem 5 (Equivalence between $\mathcal{G}$ and $\mathcal{G}'$).** Given a term $t : o$, $\| \mathcal{G}'_t \|_{IO} = \| \mathcal{G}_t \|_{IO}$.

We transform $\mathcal{G}'$ into the scheme $\mathcal{G}''$ that will directly turn into $\bot$ a redex $t$ such that $q \bot \in [t]$. For technical reason, instead of adding $\bot$ we add a non terminal $Void : o$ and a rule $Void \rightarrow Void$. $\mathcal{G}' = (\mathcal{V}', \sigma', \mathcal{N}', \mathcal{R}' \cup \{Void : o\}, \mathcal{S})$ such that $\mathcal{R}'$ contains the rule $Void \rightarrow Void$ and for all $F \in \mathcal{N}$, if $q \bot \in [F] \sigma_1 \ldots \sigma_k$ then $F^{+_{\Theta^\mathcal{V}}} \sigma_1 \ldots \sigma_k \sigma_0 x_1^{+_{\Theta^\mathcal{V}}} \ldots x_k^{+_{\Theta^\mathcal{V}}} \rightarrow Void$ otherwise we keep the rule of $\mathcal{R}'$.

The following theorem concludes Section 4.

**Theorem 6 (IO vs OI).** Let $\mathcal{G}$ be a higher-order recursion scheme. Then one can construct a scheme $\mathcal{G}'''$ having the same order of $\mathcal{G}$ such that $\| \mathcal{G}''' \| = \| \mathcal{G} \|_{IO}$.

**Proof (Sketch).** First, given a term $t : o$, one can prove that $\| \mathcal{G}'_t \|_{IO} = \| \mathcal{G}'_t \|_{IO}$.

Then take a redex $t$ such that $\| \mathcal{G}'_t \|_{IO} = \bot$, i.e. $q \bot \in [\mathcal{G}_t]$. There is only one OI derivation from $t : t \rightarrow Void \rightarrow Void \rightarrow \ldots$, then $\| \mathcal{G}' \| = \bot$. We can extend this result saying that if there is the symbol $\bot$ at node $u$ in $\| \mathcal{G}'' \|_{IO}$ then there is a node $u$ in $\| \mathcal{G}'' \|$. Hence, since $\| \mathcal{G}'' \|_{IO} \subseteq \| \mathcal{G}'' \|$, we have $\| \mathcal{G}''' \| = \| \mathcal{G}'' \|_{IO}$. Then $\| \mathcal{G}''' \| = \| \mathcal{G}'' \|_{IO} = \| \mathcal{G}'' \|_{IO} = \| \mathcal{G} \|_{IO}$.

\[\square\]

## 5 Conclusion

We have shown that value trees obtained from schemes using innermost-outermost derivations (IO) are the same as those obtained using unrestricted derivations. More precisely, given an order-$n$ scheme $\mathcal{G}$ we create an order-$(n + 1)$ scheme $\mathcal{G}'$ such that $\| \mathcal{G}'' \| = \| \mathcal{G} \|$. However, the increase of the order seems unavoidable. We also create an order-$n$ scheme $\mathcal{G}''$ such that $\| \mathcal{G}'' \| = \| \mathcal{G} \|_{IO}$. In this case the order does not increase, however the size of the scheme deeply increases while it remains almost the same in $\mathcal{G}'$.

A From OI to IO

Complement of Definitions

A \( n \) holes context is a term \( C[\bullet_1, \ldots, \bullet_n] \in \mathcal{T}(\Gamma \cup \{ \bullet_i : \tau_i \mid 1 \leq i \leq n \}) \) containing exactly one occurrence of \( \bullet_i \) for all \( i \). (We will generally omit to write the type \( \tau_i \) in the notation \( \bullet_i^\tau \)).

For all \( i_1, \ldots, i_k \leq n \) we are interested in the application

\[ t_1, \ldots, t_k \mapsto \left( C[\bullet_1, \ldots, \bullet_n] \right)_{\forall j \leq k \bullet_{i_j} = \tau_j} \]

with \( t_j \in \mathcal{T}_{\bullet_{i_j}}(\Gamma) \) for all \( j \). (notice that the order of the substitution is not important). One can consider \( \left( C[\bullet_1, \ldots, \bullet_n] \right)_{\forall j \leq k \bullet_{i_j} = \tau_j} \) as a \( n - k \) holes context. We may write \( C[\bullet_1, \ldots, \bullet_n] \) to denote the context \( C[\bullet_1, \ldots, \bullet_n] \) and extend this notation to \( \left( C[\bullet_1, \ldots, \bullet_n] \right)_{\forall j \leq k \bullet_{i_j} = \tau_j} \), for example, given the context \( C[\bullet_1][\bullet_2][\bullet_3] \), we define \( C[t_1][t_2][t_3] = (C[\bullet_1][\bullet_2][\bullet_3])_{\forall i \leq 3 \bullet_{i} = \tau_{i}} \)

Given a one hole context \( C[\bullet] \), we define inductively the head symbol sequence \( \text{hss}(C) \) which is a finite sequence of symbols of \( \Gamma \): if \( C[\bullet] = \bullet \), then \( \text{hss}(C) \) is the empty sequence, if \( C[\bullet] = \alpha \cdot C'[\bullet_1 + \cdots + \cdots + \bullet_k] \), we can state that \( t_k \) is a \( l \) holes context \( C'[\bullet_{i_1} + \cdots + \cdots + \bullet_{i_l}] \) for some \( l \). Moreover

\[ \text{hss}(C[t_1][t_{i_1}][t_{i_2}][t_{i_3}][t_{i_4}][t_{i_5}][t_{i_6}][t_{i_7}][t_{i_8}]) = \text{hss}(C[s_1][s_{i_1}][s_{i_2}][s_{i_3}][s_{i_4}][s_{i_5}][s_{i_6}][s_{i_7}][s_{i_8}]) \]

We prove this proposition by induction on the size of the context, for all \( n \). If \( C[\bullet] = \bullet \), is a 1 hole context, then the result is proven. If \( C[\bullet_1][\bullet_2][\bullet_3] = \alpha \cdot t_1 \ldots t_n \) there exists exactly one \( k \) such that \( t_k \) contains one occurrence of \( \bullet_k \), if we look all the occurrences of some \( \bullet_k \) in \( t_k \), we can state that \( t_k \) is a \( l \) holes context \( C'[\bullet_{i_1} + \cdots + \cdots + \bullet_{i_l}] \) for some \( l \).

Proposition 7. Given a \( n \) holes context \( C[\bullet_1][\ldots][\bullet_n] \), for all \( i \), for all \( t_1, \ldots, t_{i-1}, t_{i+1}, \ldots, t_n \) and \( s_1, \ldots, s_{i-1}, s_{i+1}, \ldots, s_n \):

\[ \text{hss}(C[t_1][\ldots][t_{i-1}][\bullet][t_{i+1}][\ldots][t_n]) = \text{hss}(C[s_1][\ldots][s_{i-1}][\bullet][s_{i+1}][\ldots][s_n]) \]

Proposition 8. Let \( t \) be a term, and let \( C_1[\bullet] \) and \( C_2[\bullet] \) be two contexts such that \( t = C_1[t_1] \) and \( t = C_2[t_2] \), then: either there exists a context \( C_1[\bullet] \) such that \( C_2[\bullet] = C_1[C_1[\bullet]] \) (1), or there exists a context \( C_2[\bullet] \) such that \( C_1[\bullet] = C_2[C_2[\bullet]] \) (2), or there exists a two hole context \( C_1[\bullet_1][\bullet_2] \) such that \( C_1[t_1][\bullet] = C_2[\bullet] \) and \( C[\bullet][t_2] = C_1[\bullet] \) (3).

We proceed by induction. If \( C_1[\bullet] = \bullet \), then \( C_2[\bullet] = C_1[C_1[\bullet]] \). Else \( C_1[\bullet] = \alpha \cdot s_1 \ldots s_{i-1} C_1[\bullet_1] \ldots s_{i+1} \ldots s_k \) and \( C_2[\bullet] = \alpha \cdot s_1 \ldots s_{j-1} C_2[\bullet_1] \ldots s_{j+1} \ldots s_k \). If \( i \neq j \) (we assume w.l.o.g. that \( i < j \)) we set \( C_1[\bullet_1][\bullet_2] = \alpha \cdot s_1 \ldots s_{i-1} C_1[\bullet_1] \ldots s_{i+1} \ldots s_{j-1} C_2[\bullet_2] s_{j+1} \ldots s_k \), we have that \( C[t_1][\bullet] = C_2[\bullet] \) and \( C[\bullet][t_2] = C_1[\bullet] \). If \( i = j \), then \( C_1[t_1] = C_2[t_2] \), by induction:
• Either there exists a two hole context $C'[\bullet_1][\bullet_2]$ such that $C'[t_1][\bullet] = C'_1[\bullet]$ and $C'[\bullet][t_2] = C'_2[\bullet]$, in that case we set $C[\bullet_1][\bullet_2] = a_{s_1...s_{i-1}}C'[\bullet_1][\bullet_2]s_{i+1}...s_k$, and we have $C[t_1][\bullet] = C_1[\bullet]$ and $C[\bullet][t_2] = C_1[\bullet]$.

• Or there exists a context $C''[\bullet]$ such that $C'_2[\bullet] = C'_2[C''[\bullet]]$, in that case $C_2[\bullet] = C_2[C''[\bullet]]$.

• Or there exists a context $C''[\bullet]$ such that $C'_1[\bullet] = C'_2[C''[\bullet]]$, in that case $C_1[\bullet] = C_2[C''[\bullet]]$.

Correctness of the Transformation

We remark that $\bar{t}$ does not contain any occurrence of $\Delta$, $I$ or $\delta$. We also remark that any subterms of $\bar{t}$ has type $\overline{\pi}$ for some type $\pi$, hence it can not have ground type and in particular, it is not a redex. Moreover, given two terms $t_1, t_2$, if the term $\bar{t}_1 \bar{t}_2$ is valid, then it is equal to $\bar{t}_1 \bar{t}_2$, in particular, it is an “overlined” term. It follows by induction, that given three terms $t, t_1, t_2$, if the term $\bar{t}[\bar{t}_1...\bar{t}_2]$ is well defined, then it is equal to $\bar{t}_1 \bar{t}_2$ which is also well defined.

Proof of Lemma[7] First We need the following claim.

Claim 9. For all accessible term $t$ (with unrestricted derivations), for all context $C[\bullet]$ such that $t = C[red]$ with red being a redex, $hss(C)$ only contains terminals symbols. Furthermore, the term red doesn’t contain occurrence of any terminal symbol.

Proof of Claim[7] We prove it by induction. $I$ satisfies Claim[6], $\overline{\Delta}$ too. Assume that $t = C[F \ t_1...t_k]$ satisfies Claim[9] with $k = \text{arity}(F)$ and $F \in \mathcal{N}$. If $\bar{F} x_1...x_k \rightarrow_{\overline{\gamma}} \bar{\Delta} \in \overline{\mathcal{R}}$, let $t' = C[\overline{[\gamma \ x_0...x_k]}\Delta]$. Let $C''[\bullet]$ a context and $\text{red} = \gamma s_{1...s_{\text{arity}(\gamma)}}$ with $\gamma \in \overline{\mathcal{R}}$ a redex such that $t' = C[\text{red}]$.

First, we notice that since $\overline{[\gamma \ x_0...x_k]}\Delta$ is a ground type term only containing non-terminal symbols, it is a redex, let $\rho \ r_1...r_{\text{arity}(\rho)} = \Delta = \overline{[\gamma \ x_0...x_k]}\Delta$.

Using Proposition[8] we now that there are four options:

1. either $C[\bullet] = C'[\gamma s_{1...s_{i-1}}C''[\bullet]s_{i+1}...s_{\text{arity}(\gamma)}]$ with $C''$ a context,
2. or $C[\bullet] = C[\rho \ r_1...r_{\text{arity}(\gamma)} = \Delta]$ with $C''$ a context,
3. or $C[\bullet] = C[\bullet]$,
4. or there exists a two holes context $C[\bullet_1][\bullet_2]$ such that $C[\bullet] = C[\bullet][\text{red}]$ and $C'[\bullet] = C[\overline{[\gamma \ x_0...x_k]}\Delta][\bullet]$.

Option 1 is impossible, otherwise $\gamma$ would be an element of $hss(C)$.

Option 2 would imply that $\overline{[\gamma \ x_0...x_k]}\Delta = \rho \ r_1...r_{\text{arity}(\gamma)} = \text{red} = \Delta$ and $t'$ contains a ground typed term, which can’t be true, see Remark[6].

If Option 3 is true. Then $hss(C') = hss(C)$ which by induction only contains terminal symbols. Since there is no terminal symbols in $\overline{\gamma}$ and in $t_i$ for all $i$, there is no terminal in $\overline{\gamma} \Delta = \text{red}$. Hence $t'$ satisfies Claim[9].

If Option 4 is true, then $t = C[F \ t_1...t_n][\bullet]$. Then by induction, $hss(C[F \ t_1...t_n][\bullet])$ only contains terminal symbols. But, using Proposition[7], we know that

$$hss(C'[\bullet]) = hss(C[\overline{[\gamma \ x_0...x_k]}\Delta][\bullet]) = hss(C[F \ t_1...t_n][\bullet]).$$

Then $hss(C'[\bullet])$ only contains terminal symbols. Furthermore, since $\text{red}$ is a subterm of $t$, by induction it only contains non-terminal symbols, which proves that $t'$ satisfies Claim[9].

Assume that $t = C[\bar{a} \ t_1...t_k]$ satisfies Claim[9] with $a \in \Sigma$ and $k = \text{arity}(a)$, and let $t' = C[a \ (t_1\Delta)...(t_k\Delta)]$.

We can prove that $t'$ satisfies Claim[9] in a similar way. ☐
Let \( t = C[\text{red}] \) an accessible term with red a redex, let exp be the rewrite expression of red, and let's look at the derivation \( t = C[\text{red}] \rightarrow_{\mathcal{G}} t' = C[\text{exp}] \).

Claim 9 tells us that \( \text{hss}(C) \) only contains terminals, hence there is no redex containing an occurrence of \( \bullet \) in \( C \), hence the derivation is IO. Assume that \( \text{red} = \gamma t_1...t_{i-1}C'(t)_{i+1}...t'_{\text{arity}(\gamma)} \) with \( C' \) a context and \( t \) a term.

Then \( t = C[\gamma t_1...t_{i-1}C'(t)_{i+1}...t'_{\text{arity}(\gamma)}] \) then \( \text{hss}(C[\gamma t_1...t_{i-1}C'(t)_{i+1}...t'_{\text{arity}(\gamma)}]) \) contains a non-terminal symbol \( \gamma \), hence Claim 9 tells that \( t \) is not a redex, so no non-trivial subterm of \( \text{red} \) is a redex, so the derivation is IO.

\[ \square \]

**Proof of Theorem 2** Let's show that we only have to prove that \( \|G\|_{\text{OI}} = \|\overline{G}\| \). Concretely we will show that:

\[ \forall t \in \text{Acc}_G, \exists t' \in \text{Acc}_{\overline{G}} : t^\perp \sqsubseteq (t')^\perp \quad (1) \]

\[ \forall t' \in \text{Acc}_{\overline{G}}, \exists t \in \text{Acc}_G : (t')^\perp \sqsubseteq t^\perp \quad (2) \]

**Definition 1** (\( \| \cdot \| \) transformation). We define inductively the transformation \( \| \cdot \| : \mathcal{T}^o(\Sigma \uplus \mathcal{N}) \rightarrow \mathcal{T}^o(\Sigma \uplus \overline{\mathcal{N}}) \) by:

- \( \| a t_1...t_{\text{arity}(a)} \| = a \| t_1 \| ...\| t_{\text{arity}(a)} \| \) for all \( a \in \Sigma \)
- \( \| \text{red} \| = \overset{\text{red}}{\Delta} \) for \( \text{red} \) a redex.

**Remark 1.** Notice that \( t^\perp = (\|t\|)^\perp \).

**Claim 10.** If \( t \in \mathcal{T}^o(\Sigma \uplus \mathcal{N}) \) then \( \overline{t} \Delta \rightarrow_{\overline{\mathcal{G}}} \|t\| \).

**Proof.** The proof is done by induction. If \( t \) is a redex then \( \|t\| = \overline{t} \Delta \). If \( t = a t_1...t_k \) with \( a \in \Sigma \) and \( k = \text{arity}(a) \), assume that for all \( i, \overline{t_i} \Delta \rightarrow \|t_i\| \). We have \( \overline{t} \Delta = \overline{a} \overline{t_1}...\overline{t_k} \) so \( \overline{t} \rightarrow_{\overline{\mathcal{G}}} a (\overline{t_1} \Delta)...(\overline{t_k} \Delta) \). Hence \( \overline{t} \Delta \rightarrow_{\overline{\mathcal{G}}} a \|t_1\|...\|t_k\| = \|t\| \).

\[ \square \]

**Claim 11.** For all \( t, \) if \( t \in \text{Acc}_G \), then \( \|t\| \in \text{Acc}_{\overline{G}} \). This claim implies property (1).

**Proof of Claim 11** We prove this by induction. If \( t = S, \|t\| = S \Delta, \) and \( I \rightarrow S \Delta, \) so \( \|t\| \in \text{Acc}_{\overline{G}} \).

Let \( t = C[F t_1...t_k] \in \text{Acc}_G \) with \( k = \text{arity}(F) \) and \( \text{hss}(C) \) contains only terminal symbols. Assume that \( \|t\| \in \text{Acc}_G \). Given that \( F x_1...x_k \rightarrow e \in \mathcal{R} \), let \( t' = C[e[\overline{v_i} x_i \rightarrow \overline{t_i}]] \).

First, given a ground type context \( C[\bullet^o] \), we can define the associated ground type context \( \|C[\bullet^o]\| \) by adding to Definition 1 the fact \( \|\bullet^o\| = \bullet^o \). Hence we can say that \( \|t\| = \|C[\overline{F} \overline{t_1}...\overline{t_k} \Delta] \).

We see that \( \|t\| \rightarrow_{\overline{\mathcal{G}}} \|C[\overline{F} \overline{t_1}...\overline{t_k} \Delta] \). Claim 10 shows that \( \overline{\mathcal{G}}[\overline{v_i} x_i \rightarrow \overline{t_i}] \Delta = \overline{\mathcal{G}}[\overline{v_i} x_i \rightarrow \overline{t_i}] \Delta \rightarrow_{\overline{\mathcal{G}}} \|e[\overline{v_i} x_i \rightarrow \overline{t_i}]\| \), hence \( \|t\| \rightarrow_{\overline{\mathcal{G}}} \|C[\overline{F} \overline{t_1}...\overline{t_k} \Delta] \rightarrow_{\overline{\mathcal{G}}} \|C[\overline{F} \overline{t_1}...\overline{t_k} \Delta] \| = \|t'\| \).

\[ \square \]

**Claim 12.** Given a term \( t' \in \text{Acc}_{\overline{G}} \) there exists a term \( t \in \text{Acc}_G \) such that \( t \rightarrow_{\overline{\mathcal{G}}} \|t\| \). This claim implies property (2).

**Proof of Claim 12** We will divide the relation \( \rightarrow_{\overline{\mathcal{G}}} \) in two relations: \( \rightarrow_{\overline{\mathcal{G}}} = \rightarrow_{\Sigma \uplus \overline{\mathcal{N}}} \) depending on the head symbol of the redex we're rewriting. Let \( t \rightarrow_{\overline{\mathcal{G}}} t' \) if the rewrite rule applied is \( r_{\overline{\mathcal{G}}} \) for some \( a \in \Sigma \) then \( t \rightarrow_{\overline{\mathcal{G}}} t' \); if the rewrite rule is \( r_{\mathcal{N}} \) with \( F \in \mathcal{N} \), then \( t \rightarrow_{\mathcal{N}} t' \).

The proof is in four steps:
1. Given a term \( t \in \text{Acc}_\Theta \), there is only a finite number of derivation \( t \rightarrow^* t' \), furthermore, if \( t \rightarrow^*_0 t_1 \) and \( t \rightarrow^*_1 t_2 \) such that there is no \( t' \) such that \( t_1 \rightarrow^*_1 t' \) or \( t_2 \rightarrow^*_0 t' \), then \( t_1 = t_2 \). We name this unique term \( t^\Sigma \), and we notice that if \( t \rightarrow^*_1 t' \) then \( t' \rightarrow^*_2 t^\Sigma \). Basically this step comes from the fact that the relation \( \rightarrow_\Sigma \) strictly decrease the number of occurrences of terms headed by some \( \alpha \) with \( \alpha \in \Sigma \).

2. Let \( t = C[F_{t_1} \ldots F_{t_{\text{arity}(\Sigma)}}] \), then \( t^\Sigma = C^\Sigma[F_{t_1} \ldots F_{t_{\text{arity}(\Sigma)}}] \), \( C^\Sigma \) being defined inductively: if \( C[\cdot] = \bullet \) then \( C^\Sigma[\cdot] = \bullet \), if \( C[\cdot] = a \) \( t_1 \ldots t_m \), then \( C^\Sigma[\cdot] = a \) \( t_1^\Sigma \ldots t_m^\Sigma \) (Claim \( \Box \) shows that these are the only possibilities). This step is shown by induction.

3. If \( t \rightarrow \eta t' \) i.e. \( t = C[F_{t_1} \ldots t_k] \) and \( t' = C[F_{[t_1, \ldots, t_k]} \Delta] \) with the appropriate \( \Delta \), let \( t'' = C[\bar{\sigma} \eta_{i \in \eta} \pi_1] \Delta \), then \( t^\Sigma = \|t''\|_\Sigma \).

4. Finally we prove by induction that for all \( t' \), there exists \( t \in \text{Acc}_G \) such that \( t^\Sigma = \|t\| \), which proves the claim.

\[ \square \]

\[ \square \]

**B  The Type System Detailed**

We give here a complete proof of Theorem \( \Box \) and Proposition \( \Box \). We first recall the type system, and the definition of \( \vdash (G,t) \gg \sigma \).

\[ \frac{\Theta \vdash t \gg \theta_1 \ldots \theta_n}{\Theta \vdash t \gg \\{\theta_1, \ldots, \theta_n\}} \text{ (Set)} \]

\[ \frac{\Theta, \alpha \gg \\{\theta_1, \ldots, \theta_n\} \vdash \alpha \gg \theta_i}{\Theta \vdash a \gg \sigma_1 \rightarrow \ldots \rightarrow \sigma_{\leq \text{arity}(a)} \rightarrow q_\infty(\Sigma) \text{ (for } a \in \Sigma \text{ and } \exists j \sigma_j = q_\infty)} \text{ (for all } i \text{) (At)} \]

\[ \frac{\Theta \vdash t_1 \gg \theta, \Theta \vdash t_2 \gg \sigma}{\Theta \vdash t_1 \gg \theta \rightarrow \Theta \vdash t_2 \gg \sigma} \text{ (App)} \]

\[ \frac{\Theta \vdash t \gg q_\infty \rightarrow q_\infty I \text{ (if } t : \tau_1 \rightarrow \tau_2)}{\Theta \vdash t_1 \gg q_\infty \rightarrow q_\infty I} \]

\[ \Theta \vdash t_1 \gg q_\infty \rightarrow q_\infty I \]

Remark that:

- Using rule (Set) one can always prove, for any term \( t \), \( \Theta \vdash t \gg \\{\} \).
- \( \Theta \vdash t \gg \\{\theta_1, \ldots, \theta_k\} \) if and only if , for all \( i \), \( \Theta \vdash t \gg \theta_i \).
- There is no rules that directly involve \( q_\perp \), but that does not mean that no term matches \( q_\perp \), since it can appear in \( \Theta \). Rules like (At) or (App) may be used to state that a term matches \( q_\perp \).

We say that \( (G,t) \) matches the conjunctive mapping \( \sigma \) written \( \vdash (G,t) \gg \sigma \) if there exists an environment \( \Theta \), called a witness environment of \( \vdash (G,t) \gg \sigma \), which verifies the following properties:

1. \( \text{Dom}(\Theta) = \mathcal{N} \).
2. \( \forall F : \tau \in \mathcal{N} \Theta(F) :: \tau \),
3. If $F \cdot x_1..x_k \to e \in R$ and $\Theta \vdash F \triangleright \sigma_i \to \ldots \to \sigma_{i\leq k} \to q$ then either there exits $j$ such that $q_\infty \in \sigma_j$, or $i = k$ and $\Theta, x_1 \triangleright \sigma_1, \ldots, x_k \triangleright \sigma_k \vdash e \triangleright q$.

4. $\Theta \vdash t \triangleright \sigma$.

**Lemma 13** (Isolated Non Terminals). Given a non terminal $F$ that has not ground type. Then if $\Theta$ verifies properties 1 to 3, one cannot prove $\Theta \vdash F \triangleright q_\infty$.

**Proof of Lemma 13** The proof comes from the fact that $\Theta$ verifies property 3. Assume $\Theta \vdash F \triangleright \sigma_1 \to \ldots \to \sigma_i \to q_\infty$. Property 3 states that if $i \leq \text{arity}(F)$ then there exists $j \leq i$ such that $q_\infty \in \sigma_j$ in particular $i \neq 0$. If $i = \text{arity}(F)$ then by hypothesis, $i \neq 0$. Then, one cannot prove $\Theta \vdash F \triangleright q_\infty$. □

**Lemma 14** (Non fully-applied terminals). Let $\Theta$ be an environment that verifies properties 1 to 3, let $F$ be a non terminal that has not ground type and let $t = F \cdot t_1 \ldots t_i$ with $i < \text{arity}(F)$. If $\Theta \vdash F \cdot t_1 \ldots t_i \triangleright q_\infty$ then there exists $j \leq i$ such that $\Theta \vdash t_i \triangleright q_\infty$.

**Proof of Lemma 14** We prove by induction on $l$ the following more general result: if $\Theta \vdash F \cdot t_1 \ldots t_l \triangleright \sigma_{i+1} \to \ldots \to \sigma_i \to q_\infty$ with $F \in \mathcal{N}$ and $i < \text{arity}(F)$, then there exists $j \leq i$ such that $\Theta \vdash t_j \triangleright q_\infty$ if $j \leq l$ or $q_\infty \in \sigma_j$ if $j > l$.

If $l = 1$, then the rule we used to prove $\Theta \vdash F \cdot t_1 \triangleright \sigma_2 \to \ldots \to \sigma_i \to q_\infty$ could not be $(q_\infty I)$ since one cannot prove $\Theta \vdash F \triangleright q_\infty$. If the rule we used were $(q_\infty \to q_\infty I)$, then $q_\infty \in \sigma_2$. If it is rule $(App)$ then $\Theta \vdash F \cdot t_1 \to \sigma_2 \to \ldots \to \sigma_i \to q_\infty$ and $\Theta \vdash t_1 \triangleright \sigma_1$, and since $i < \text{arity}(F)$, property 3 states that there exists $j < l$ such that $\Theta \vdash t_j \triangleright q_\infty$ if $j < l$, $q_\infty \in \sigma_j$ elsewise. These are the only rules we could have applied.

If $l > 1$. If we applied rule $(q_\infty I)$ then $\Theta \vdash F \cdot t_1 \ldots t_l \triangleright q_\infty$ by induction hypothesis. There exists $j \leq l$ such that $\Theta \vdash t_j \triangleright q_\infty$. If we applied rule $(q_\infty \to q_\infty l)$, then $q_\infty \in \sigma_{i+1}$. If we applied rule $(App)$ then $\Theta \vdash F \cdot t_1 \ldots t_l \triangleright \sigma_{i+1} \to \ldots \to \sigma_i \to q_\infty$ and $\Theta \vdash t_j \triangleright \sigma_1$, then by induction hypothesis there exists $j < l$ such that $\Theta \vdash t_j \triangleright q_\infty$ if $j < l$, $q_\infty \in \sigma_j$ if $j > l$. If $j < l$ then either $j < l$ and then $\Theta \vdash t_j \triangleright q_\infty$, or $j = l$ and $q_\infty \in \sigma_j$ hence $\Theta \vdash t_j \triangleright q_\infty$, if $j > l$ then $q_\infty \in \sigma_j$ if $j > l$.

□

**Lemma 15** (Redexes and $q_\infty$). (1) If $\Theta$ verifies properties 1 to 3, then given a term $t$, if $\Theta \vdash t \triangleright q_\infty$ then either $t$ contains a redex $r$ such that $\Theta \vdash r \triangleright q_\infty$. In particular, if $t$ does not contains any redex, then one cannot prove $\Theta \vdash t \triangleright q_\infty$.

(2) If $\Theta$ verifies properties 1 to 3, then given a term $t$, if $t$ contains a redex $r$ such that $\Theta \vdash r \triangleright q_\infty$ then one can prove $\Theta \vdash t \triangleright q_\infty$.

**Proof of Lemma 15**

(1) We prove (1) by induction on $t$. Assume that $\Theta \vdash t \triangleright q_\infty$.

If $t : o$ then either $t = F \cdot t_1 \ldots t_k$ in which case $t$ is the redex $r$, or $t = a \cdot t_1 \ldots t_k$ then the only rule we could have applied to prove $\Theta \vdash t \triangleright q_\infty$ is $(\Sigma)$, then there exists $t_j : o$ such that $\Theta \vdash t_j \triangleright q_\infty$, and the result comes by induction.

If $t : \tau$ with $\tau \neq o$. We could not have $t = F \in \mathcal{N}$ since one cannot prove $\Theta \vdash F \triangleright q_\infty$ if $F$ has not ground type. If $t = a \cdot t_1 \ldots t_k$, then again there exists $t_j : o$ such that $\Theta \vdash t_j \triangleright q_\infty$, and the result comes by induction. If $t = F \cdot t_1 \ldots t_k$, $F$ has not ground type, and $i < \text{arity}(F)$ since $t$ has not ground type. Then Lemma 14 states that there exists $t_j$ such that $\Theta \vdash t_j \triangleright q_\infty$ and the result comes by induction.

To prove (2), assume that there is a redex $r$ such that $\Theta \vdash r \triangleright q_\infty$ and $t = C[r]$. We prove the result by induction on $C[\cdot]$. If $C[\cdot] = o$, then $t = r$ therefore $\Theta \vdash r \triangleright q_\infty$. Assume $t = t_1 t_2$ with $t_1 = C'[r]$ or $t_2 = C'[r]$. If $t_1 = C'[r]$ then by induction hypothesis, one can prove $\Theta \vdash t_1 \triangleright q_\infty$, and then, using rule $q_\infty I$, $\Theta \vdash t_1 t_2 \triangleright q_\infty$. If $t_2 = C'[r]$, by induction hypothesis, one can prove $\Theta \vdash t_2 \triangleright q_\infty$, using rule $(q_\infty \to q_\infty I)$, we have $\Theta \vdash t_1 \triangleright q_\infty \to q_\infty$ and then, rule $(App)$ gives us $\Theta \vdash t_1 t_2 \triangleright q_\infty$. □
Lemma 16 (Ground type terms and $q_\bot$). If $\Theta$ verifies properties 1 to 3, then if $t : \tau$ and $\Theta \vdash t \triangleright \sigma$, $\sigma :: \tau$. In particular, if $\Theta \vdash t \triangleright q_\bot$, then $t : o$.

Proof of Lemma 16 We can assume, without loss of generality that $\sigma = \{ \theta \}$ for some atomic mapping $\theta$. We prove this by induction on the structure of $t$.

If $t = \alpha$ with $\alpha \in \Sigma \cup \mathcal{N}$, then the only rules we can apply are (At), (Σ) and ($q_\infty \rightarrow q_\infty \ I$) and they all satisfy the property.

If $t = t_1 t_2$ with $t_1 : \tau_1 \rightarrow \tau$ and $t_2 : \tau_2$, then the types we can apply are either ($q_\infty$) or (App). If it is ($q_\infty$) then we have proven $\Theta \vdash t \triangleright q_\infty$ and $q_\infty :: \tau$. If it is (App) it means that we have proven $\Theta \vdash t_1 \triangleright \sigma' \rightarrow \theta$ and $\Theta \vdash t_2 \triangleright \sigma'$, and by induction hypothesis, $\sigma' :: \tau_2$ and $\theta :: \tau$.

Theorem 17 (Soundness). Let $G$ be an HORS, and $t$ be term (of any type), if $\vdash (G, t) \triangleright q_\infty$ (resp. $\vdash (G, t) \triangleright q_\bot$) then $\mathcal{P}_o(t)$ (resp. $\mathcal{P}_\bot(t)$) holds.

Proof of Theorem 17

Lemma 18 (Type Preservation). Let $t : \tau$ be a term. If $\vdash (G, t) \triangleright \sigma$ and $t \rightarrow_{IO} t'$ then $\vdash (G, t') \triangleright \sigma$.

Proof of Lemma 18 Assume that $\vdash (G, t) \triangleright \sigma$ and $t \rightarrow_{IO} t'$. Let $\Theta$ be a witness environment of $\vdash (G, t) \triangleright \sigma$, we will prove that it is also a witness environment of $\vdash (G, t') \triangleright \sigma$ (we only have to check that $\Theta \vdash t' \triangleright \sigma$).

We know that $t = C[F s_1 \ldots s_k]$ and $t' = C[e_{\forall [yi \rightarrow x_i]}]$ for some context $C[x : \alpha] : \tau$. We proceed by induction on $C[x]$. If $C[x] = \bullet$, we can assume without loss of generality that $\sigma = q \in Q$. We look at the proof of $\vdash (G, t') \triangleright \sigma$ and remark that either (1) the proof contains $\Theta \vdash F \triangleright \sigma_1 \rightarrow \ldots \rightarrow \sigma_k \rightarrow \sigma$ and $\Theta \vdash s_i \triangleright \sigma_i$ for all $i$ and the last steps are using the rule (App), or (2) the proving tree contains $\Theta \vdash F s_1 \ldots s_i \triangleright q_\infty \rightarrow q_\infty$ and $\Theta \vdash s_{i+1} \triangleright q_\infty$, the last steps are using the rule (App) once and then only rule ($q_\infty$I). The former case is impossible: since $t \rightarrow_{IO} t'$ is an IO derivation there’s no redex in $s_i$ for all $i$, hence Lemma 15 shows that one cannot have $\Theta \vdash s_{i+1} \triangleright q_\infty$.

Hence the proving tree contains $\Theta \vdash F \triangleright \sigma_1 \rightarrow \ldots \rightarrow \sigma_k \rightarrow \sigma$ and $\Theta \vdash s_i \triangleright \sigma_i$ for all $i$, then $\Theta, x_1 \triangleright \sigma_1, \ldots, x_k \triangleright \sigma_k \vdash e \triangleright q$, and if we replace all statements of $x_i \triangleright \sigma_i$ by the proof of $\Theta \vdash s_i \triangleright \sigma_i$, we obtain a proof of $\Theta \vdash e_{\forall [yi \rightarrow x_i]} \triangleright \sigma$.

Now we prove the induction step. Assume that $C = C' \{ \bullet \} t_2$ or $C = t_1 C' \{ \bullet \}$, then $t = t_1 t_2$ with either $t_1 = C'[F s_1 \ldots s_k]$ or $t_2 = C'[F s_1 \ldots s_k]$. Then $t' = t'_1 t'_2$ with respectively, either $t'_1 = C'[e_{\forall [yi \rightarrow x_i]}]$ and $t'_2 = t_2$, or $t'_1 = t_1$ and $t'_2 = C'[e_{\forall [yi \rightarrow x_i]}]$. Either way, by induction hypothesis, if $\Theta \vdash t_1 \triangleright \sigma_1$ (resp. $\Theta \vdash t_2 \triangleright \sigma_2$), then $\Theta \vdash t'_1 \triangleright \sigma_1$ (resp. $\Theta \vdash t'_2 \triangleright \sigma_2$). Assume we have proven $\Theta \vdash t \triangleright \sigma$. In order to do it, either we have use rule ($q_\infty$I) or rule (App), either way we could use the same rule to prove $\Theta \vdash t' \triangleright \sigma$.

We extend in an intuitive way the properties $\mathcal{P}_\bot$ and $\mathcal{P}_o$ to trees: if $t$ is a tree then $\mathcal{P}_\bot(t) = "t = \bot"$ and $\mathcal{P}_o(t) = "t is either infinite or contains \bot."$

Lemma 19 (Weak Soundness). Given a term $t : o$, (1) if $\vdash (G, t) \triangleright q_\bot$, then $\mathcal{P}_\bot(t^+)\bot$ holds, (2) if $\vdash (G, t) \triangleright q_\infty$, then $\mathcal{P}_o(t^+)\bot$ holds.

Proof of Lemma 19 We can use Lemma 15 to prove (2): if $\vdash (G, t) \triangleright q_\infty$ then $t$ contains a redex, hence $t^+$ contains $\bot$, therefore $\mathcal{P}_o(t^+)\bot$ holds.

We prove (1) by induction on the structure of $t^+$. If $t^+ = \bot$ then $P_\bot(t^+)$ is true hence (1) holds. If $t^+ = a$ with $a \in \Sigma$, then $t = a$ and there is no rule that we can apply to state $\vdash (G, a) \triangleright q_\bot$, hence (1) and (2) holds. If $t^+ = a t'_1 \ldots t'_k$ with $k > 0$, then $t = a t_1 \ldots t_k$ with $a \in \Sigma$ and $t'_1 = t'_i$ for all $i$. For all
environment Θ, we show by induction that for all i, if Θ ⊩ a t₁...tᵢ ▷ σ′ then σ′ = σ₁ → ... → σᵢ → qᵦ:
The term a can only be judge by the rule (Σ) hence it is true if i = 0, the term (a t₁...tᵢ) tᵢ₊₁ can be
judge by rules (qᵦ I), (qᵦ → qᵦ) and (App) and by induction hypothesis, in all three cases, we get
Θ ⊩ a t₁...tᵢ ▷ σ₁ → ... → σᵢ → qᵦ for some l. In particular, we don’t have ⊩ (G,t) ▷ qₐ, hence (1)
holds.

Using Lemma 1 and 2, in order to prove Theorem 17 we can assume that t : o. We prove it by
contradiction. Assume that ⊩ (G,t) ▷ qᵦ but Pᵦ(t) doesn’t hold. Then it means that ||Gᵦ|| is finite and
contains only terminals. Since it’s finite, there exists a finite IO derivation from t that leads to ||Gᵦ||:
t ⊩ᵦ ||Gᵦ|| hence using Lemmas 18 and 19 we can prove Pᵦ((||Gᵦ||)ᵦ), but since ||Gᵦ|| is a tree,
||Gᵦ|| = (||Gᵦ||₀)ᵦ, hence ||Gᵦ|| is infinite or contains ⊥ which raises a contradiction.

We treat the case ⊩ (G,t) ▷ qₐ the same way: Assume that ⊩ (G,t) ▷ qₐ but Pₐ(t) doesn’t hold. Then
it means that ||Gᵦ|| contains some terminals. Then there exists a finite IO derivation from t that leads to a
term t’ such that t’ = ⊥: t ⊩ᵦ t’, hence using Lemmas 18 and 19 we can prove Pₐ((t’)ᵦ) which is false.

Theorem 20 (Completeness). Let G be an HORS, if Pᵦ(t) (resp. Pₐ(t)) holds then ⊩ (G,t) ▷ qᵦ (resp.
<br>Ⅱ (G,t) ▷ qₐ).

Proof of Theorem 20

Using Lemma 15 we can assume without loss of generality that t has ground type.

We recall the properties that an environment Θ has to satisfy in order to be a witness of ⊩ (G,t) ▷ σ.

1. Dom(Θ) = N,
2. ∀F : τ ∈ N Θ(F) :: τ,
3. if “F x₁...xₖ → e”∈ R and Θ ⊩ F ▷ σ₁ → ... → σᵢ<ₖ → q then either there exists j such that qᵦ ∈ σⱼ,
   or i = k and Θ, x₁ ▷ σ₁,..., xₖ ▷ σₖ ⊩ e ▷ q,
4. Θ ⊩ t ▷ σ.

Let E be the set of environment that matches properties 1 and 2. Let F : E → E be a mapping such
that for all F : τ₁ → ... → τₖ → o ∈ N, if F x₁,...xₖ → e ∈ E then,

F(Θ)(F) = { σ₁ → ... → σₖ → q | q ∈ Q ∧ ∃i σᵢ :: τᵢ ∧ Θ, x₁ ▷ σ₁,..., xₖ ▷ σₖ ⊩ e : q }
∪ { σ₁ → ... → σᵢ<ₖ → qᵦ | ∧ ∃i σᵢ :: τᵢ ∧ σᵢ → qᵦ ∈ σⱼ }
      ∪ { σ₁ → ... → σₖ → qₐ | ∀i σᵢ :: τᵢ ∧ ∃j qᵦ ∈ σⱼ }.

Let Θ₀ ∈ E be the environment such that, for all F : τ = τ₁ → ... → τₖ → o ∈ N, Θ₀(F) is defined and
contains all atomic mappings θ :: τ. Notice that:

Θ₀(F) = { σ₁ → ... → σₖ → q | q ∈ Q ∧ ∃i σᵢ :: τᵢ } ∪ { σ₁ → ... → σᵢ<ₖ → qᵦ | ∀i j σᵢ :: τᵢ ∧ ∃j qᵦ ∈ σⱼ }.

Lemma 21 (Universal Witness). There exists m ∈ N such that the judgment ⊩ (G,t) ▷ σ holds if and only
if F(m)(Θ₀) ⊩ t ▷ σ (This is Proposition 4 with Θ* = F(m)(Θ₀)).

Proof of Lemma 21 We define the partial order ⊆ on E such that Θ₁ ⊆ Θ₂ if and only if, for all F ∈ N,
Θ₁(F) ⊆ Θ₂(F). Note that if Θ₁ ⊆ Θ₂ and Θ₁ ⊩ t ▷ σ then Θ₂ ⊩ t ▷ σ. Θ₀(F) contains all atomic mappings
θ :: τ, hence Θ₀ is a maximum of E with respect to ⊆. Note that the mapping F is monotonic with
respect to \(c\) (i.e. if \(\Theta \sqsubseteq \Theta'\) then \(\mathcal{F}(\Theta) \sqsubseteq \mathcal{F}(\Theta')\)). Given \(\Theta \in \mathcal{E}\), we say that \(\Theta\) is a post-fixpoint of \(\mathcal{F}\) if and only if \(\Theta \sqsubseteq \mathcal{F}(\Theta)\). Remark that being a post-fixpoint of \(\mathcal{F}\) is the same as verifying property 3.

Since \(\Theta_0\) is a maximum of \(\mathcal{E}\), and \(\mathcal{F}(\Theta_0) \in \mathcal{E}\), then \(\Theta_0 \sqsupseteq \mathcal{F}(\Theta_0)\), therefore, since \(\mathcal{F}\) is monotonic, \(\Theta_0 \sqsupseteq \mathcal{F}(\Theta_0) \sqsupseteq \mathcal{F}(\mathcal{F}(\Theta_0)) \supseteq \ldots\). Because \(\mathcal{E}\) is finite, there exists \(m\) such that \(\mathcal{F}^m(\Theta_0) = \mathcal{F}^{m+1}(\Theta_0)\), in particular \(\mathcal{F}^m(\Theta_0)\) is a post-fixpoint of \(\mathcal{F}\), hence it verifies properties 1, 2, and 3.

Take a witness \(\Theta\) of \(\vdash (G,t) \triangleright \sigma\). \(\Theta\) is a post-fixpoint of \(\mathcal{F}\), and since \(\mathcal{F}^m(\Theta_0)\) is the greatest post-fixpoint, \(\mathcal{F}^m(\Theta_0) \sqsupseteq \Theta\), hence \(\mathcal{F}^m(\Theta_0) \vdash t \triangleright \sigma\), thus \(\mathcal{F}^m(\Theta_0)\) is a witness of \(\vdash (G,t) \triangleright \sigma\).

\[\square\]

Let \(G^{(m)} = \langle \mathcal{N}, \Sigma, \mathcal{N}^{(m)} \cup \{\text{Void} : o\}, R^{(m)}, I \rangle\) be the scheme such that \(\mathcal{N}^{(m)} = \bigcup_{0 \leq i \leq m}\{F_i \mid F \in \mathcal{N}\}\).

For all \(F \ x_1 \ldots x_k \rightarrow e \in \mathcal{R}\), \(R^{(m)}\) contains the following rewrite rules:

\[F_i x_1 \ldots x_k \rightarrow e_{[\forall H \in \mathcal{N} \ H \rightarrow H_{i-1}]} \quad \text{for } i > 0\]

\[F_0 x_1 \ldots x_k \rightarrow e_{[\forall H \in \mathcal{N} \ H \rightarrow H_0]}\]

\[F_0 x_1 \ldots x_k \rightarrow \text{Void}\]

\[\text{Void} \rightarrow \text{Void}\]

Notice that \text{Void} here is a non-terminal of order 0 that produce itself. Hence applying its rewrite rule to a term would produce the same term. In the following we forbid this rule to be applied. \(G^{(m)}\) with this restriction is said to be recursion free, i.e. the graph whose vertices are the non terminals and where there is an edge from \(F\) to \(G\) if and only if there exist an allowed rewrite rule \(F \ x_1 \ldots x_k \rightarrow e\) such that \(e\) contains an occurrence of \(G\), has no loop. Such non-recursive schemes are known to be strongly normalizing, i.e. for any term \(t\) all derivations using only allowed rewrite rules are finite. In particular, there exists a finite IO derivation \(t \rightarrow_{IO} t'\) such that \(\|t'\|_o = \|t\|_o\).

We define the environment \(\Theta^{(m)}\) on \(\mathcal{N}^{(m)} \cup \{\text{Void}\}\): for all \(F \in \mathcal{N}\), for all \(i \leq j\), \(\Theta^{(m)}(F_i) = \mathcal{F}^i(\Theta_0)(F)\) and \(\Theta^{(m)}\)(\text{Void}) = \bigwedge\{q_o, q_\bot\}.

**Lemma 22.** Given a two terms \(t, t' \in \mathcal{F}(\Sigma \cup \mathcal{N}^{(m)})\) such that \(t \rightarrow_{IO} t'\) is allowed in \(G^{(m)}\). If \(\Theta^{(m)} \vdash t' \triangleright \sigma\), then \(\Theta^{(m)} \vdash t \triangleright \sigma\).

**Proof of Lemma 22** We proceed by induction on the structure of \(t\). We prove the initial case: \(t = F_i s_1 \ldots s_k\) and \(t' = e_{[\forall i, x_i \rightarrow s_i]}\) with \(F_i x_1 \ldots x_k \rightarrow e \in \mathcal{R}\). We assume without loss of generality that \(\sigma\) is atomic, hence \(\sigma = q \in Q\). Let \(\sigma_i\) be the union of all mappings assigned to \(s_i\) in the proof of \(\Theta^{(m)} \vdash e_{[\forall i, x_i \rightarrow s_i]} \triangleright q\). Then we have \(\Theta^{(m)}, x_1 \triangleright \sigma_i, \ldots, x_k \triangleright \sigma_k \vdash e \triangleright q\). Let \(\Theta' = \Theta^{(m)}, F_i \triangleright \sigma_i \rightarrow \ldots \rightarrow \sigma_k \rightarrow q\). Since \(\Theta' \vdash F_i \triangleright \sigma_i \rightarrow \ldots \rightarrow \sigma_k \rightarrow q\) and \(\Theta' \vdash s_j \triangleright \sigma_j\) (indeed, \(\Theta^{(m)} \subseteq \Theta'\)), we can prove \(\Theta' \vdash t \triangleright q\). If \(l = 0\), by definition, \(F \triangleright \sigma_1 \rightarrow \ldots \rightarrow \sigma_k \rightarrow q \in \Theta_0(F)\), and since \(\Theta^{(m)}(F_0) = \Theta_0(F)\), we have \(F \triangleright \sigma_1 \rightarrow \ldots \rightarrow \sigma_k \rightarrow q \in \Theta^{(m)}(F_0)\), hence \(\Theta' = \Theta^{(m)}\). If \(l > 0\), \(e\) only contains terminals of the form \(G_{i-1}\), then we can transform the proof of \(\Theta^{(m)}(x_1 \triangleright \sigma_1, \ldots, x_k \triangleright \sigma_k \vdash e \triangleright q)\) to obtain a proof of \(\mathcal{F}^{l-1}(\Theta_0), x_1 \triangleright \sigma_1, \ldots, x_k \triangleright \sigma_k \vdash e_{[\forall G \in \mathcal{N} \ G_{i-1} \rightarrow G]} \triangleright q\).

Then by definition of \(\mathcal{F}\), \(F \triangleright \sigma_1 \rightarrow \ldots \rightarrow \sigma_k \rightarrow q \in \mathcal{F}^{l-1}(\Theta_0)(F)\), and since \(\Theta^{(m)}(F_i) = \mathcal{F}^i(\Theta_0)(F)\), we have \(\sigma_1 \rightarrow \ldots \rightarrow \sigma_k \rightarrow q \in \Theta^{(m)}(F_i)\), hence \(\Theta' = \Theta^{(m)}\). Thus \(\Theta^{(m)} \vdash t \triangleright q\).

For the induction step, we assume without loss of generality that \(\sigma = \bigwedge\{\theta\}\). Assume that \(C = C'[\bullet] t_2\) or \(C = t_1 \ C'[\bullet]\), then \(t = t_1 t_2\) with either \(t_1 = C'[F \ s_1 \ldots s_k]\) or \(t_2 = C'[ F \ s_1 \ldots s_k]\). Then \(t' = t_1' t_2'\) with respectively, either \(t_1' = C'[e_{[\forall i, x_i \rightarrow s_i]}]\) and \(t_2' = t_2\), or \(t_1' = t_1\) and \(t_2' = C'[e_{[\forall i, x_i \rightarrow s_i]}]\). Either way, by induction hypothesis, if \(\Theta^{(m)} \vdash t_1' \triangleright \sigma_1\) (resp. \(\Theta^{(m)} \vdash t_2' \triangleright \sigma_2\)), then \(\Theta^{(m)} \vdash t_1 \triangleright \sigma_1\) (resp. \(\Theta^{(m)} \vdash t_2 \triangleright \sigma_2\)). Assume we
have proven $\Theta^{(m)} \vdash t' \triangleright \sigma$. In order to do it, either we have used rule $(q_\infty I)$ or rule $(App)$, either way we could use the same rule to prove $\Theta^{(m)} \vdash t \triangleright \sigma$.

\[ \square \]

**Lemma 23** (Terms that contains Void). Given a term $t$ that contains the non terminal Void, one can prove $\Theta^{(m)} \vdash t \triangleright q_\infty$.

**Proof of Lemma 23** We prove the result by induction on the structure of $t :$ if $t = \text{Void}$ then we use rule $(At)$, if $t = G_j t_1 \ldots t_i$ with $G_j \in \mathcal{N}^{(m)}$ and $t_i$ contains Void for some $\ell \leq i$, then by induction hypothesis, $\Theta^{(m)} \vdash t_1 \triangleright q_\infty$. Using rule $(Set)$ we have, for all $\ell' \neq \ell$, $\Theta^{(m)} \vdash t_\ell \triangleright \emptyset$. We have by construction $\Theta^{(m)} \vdash a \triangleright \sigma_1 \rightarrow \ldots \rightarrow \sigma_k \rightarrow q_\infty$ for $\sigma_j = q_\infty$ and $\sigma_i = \emptyset \forall i \neq j$. Then, if we apply $k$ times rule $(App)$ we can prove $\Theta^{(m)} \vdash a_1 \ldots a_k \triangleright q_\infty$. By definition, if $\sigma_i \neq \ell \rightarrow \emptyset$, we have $\sigma_1 \rightarrow \ldots \rightarrow \sigma_k \rightarrow q_\infty \in \Theta^{(m)} (G_j)$. Hence one can prove $\Theta^{(m)} \vdash t_i \triangleright q_\infty$.

if $t = G_j t_1 \ldots t_i$ with $a \in \Sigma$ and $t_i$ contains Void for some $\ell \leq i$ the proof is similar except we use rule $(\Sigma)$ to prove $\Theta^{(m)} \vdash a \triangleright \sigma_1 \rightarrow \ldots \rightarrow \sigma_\ell \rightarrow q_\infty$ with $\sigma_j \neq \ell \rightarrow \emptyset$ and $\sigma_\ell = q_\infty$.

\[ \square \]

**Lemma 24** (Weak Completeness). Given a term $t : o \in \mathcal{T} (\emptyset \cup \mathcal{N}^{(m)})$, if $\mathcal{P}_{\bot} (t \downarrow)$ (resp. $\mathcal{P}_\emptyset (t \downarrow)$) holds and if there exists no IO allowed rewrite rule we can apply in $t$, then $\Theta^{(m)} \vdash t \triangleright q_\bot$ (resp. $\emptyset \vdash t \triangleright q_\bot$).

**Proof of Lemma 24** We prove both results simultaneously by induction on the structure of $t$. If $t = \text{Void}$ then one can directly prove both result using rule $(At)$. We know that $t \neq a$ with $a \in \Sigma$ since $\mathcal{P}_{\bot} (a)$ (resp. $\mathcal{P}_\emptyset (a)$) does not hold. If $t = a_1 \ldots a_k$ with $a \in \Sigma$ and $t_i$ contains Void for some $\ell \leq i$, then by induction hypothesis, $\Theta^{(m)} \vdash a_1 \rightarrow \ldots \rightarrow a_k \rightarrow q_\infty$. Furthermore there exists no allowed rewrite rule we can apply in $t_i$ else we could apply it in $t$. Therefore, by induction hypothesis, $\Theta^{(m)} \vdash a \triangleright \emptyset$. Using rule $(Set)$ we have, for all $\ell' \neq \ell$, $\Theta^{(m)} \vdash a \triangleright \emptyset$. Rule $(\Sigma)$ gives $\Theta^{(m)} \vdash a_1 \rightarrow \ldots \rightarrow a_k \rightarrow q_\infty$ for $\sigma_j = q_\infty$ and $\sigma_\ell = \emptyset$. Then, if we apply $k$ times rule $(App)$ we can prove $\Theta^{(m)} \vdash a_1 \ldots a_k \triangleright q_\infty$.

Assume now that $t = F_1 t_1 \ldots t_k$ with $F_i \in \mathcal{N}^{(m)}$. Since there exists no IO allowed rewrite rule we can apply in $i$ it means that there exists $i$ such that $t_i$ contains a redex, but this redex can’t be applied, in other words, $t_i$ contains Void. Using Lemma 23 we have $\Theta^{(m)} \vdash t_i \triangleright q_\infty$. By definition, if $\sigma_j \neq \emptyset$, we have $\sigma_1 \rightarrow \ldots \rightarrow \sigma_k \rightarrow q \in \Theta^{(m)} (F_i)$ for $q \in Q$. Hence one can prove $\Theta^{(m)} \vdash t \triangleright q$.

\[ \square \]

Now, we can prove the Theorem. Given a term $t : o \in \mathcal{T} (\emptyset \cup \mathcal{N})$, assume that $\mathcal{P}_{\bot} (t)$ (resp. $\mathcal{P}_\emptyset (t)$) holds. We define the term $t^{(m)} : o \in \mathcal{T} (\emptyset \cup \mathcal{N}^{(m)})$ such that $t^{(m)} \rightarrow_{\bot} t'$ (resp. $t^{(m)} \rightarrow_{\emptyset} t'$). Notice that $\mathcal{P}_{\bot} (t^{(m)})$ (resp. $\mathcal{P}_\emptyset (t^{(m)})$) holds. Let $t' : o \in \mathcal{T} (\emptyset \cup \mathcal{N}^{(m)} \cup \bot)$ such that $t^{(m)} \rightarrow_{\bot} t'$ (resp. $t^{(m)} \rightarrow_{\emptyset} t'$) we have seen previously that such $t'$ exists. Lemma 24 states that $\Theta (t^{(m)}) \vdash t' \triangleright q_\bot$ (resp. $\Theta (t^{(m)}) \vdash t' \triangleright q_\emptyset$), then, Lemma 22 shows that $\Theta (t^{(m)}) \vdash t \triangleright q_\bot$ (resp. $\Theta (t^{(m)}) \vdash t \triangleright q_\emptyset$). Since non terminals in $t^{(m)}$ have the form $F_m \in \mathcal{F}$, if we restrict the domain of $\Theta (t^{(m)})$ only to $\{ F_m \mid F \in \mathcal{N} \}$ the proof still holds, furthermore in this proof, if we remove all “$m$” subscripts, we get $\mathcal{F} (t^{(m)}) \rightarrow_{\bot} t' \triangleright q_\bot$ (resp. $\mathcal{F} (t^{(m)}) \rightarrow_{\emptyset} t' \triangleright q_\emptyset$). Lemma 21 allows us to conclude: $\vdash (G,t) \triangleright q_\bot$ (resp. $\vdash (G,t) \triangleright q_\emptyset$).

\[ \square \]
C Selfcorrecting Scheme

Proof of Theorem [5]

Lemma 25 (Equality of Trees). Let \( t : o \in \mathcal{T}(\mathcal{V} \sqcup \mathcal{N}) \) be a term, then \( t^\perp = (t^+)^\perp \).

Proof of Lemma 25. We prove it by induction on the structure of \( t : o \). If \( t = F_{t_1...t_k} \) with \( F \in \mathcal{N} \) then \( t^\perp = \perp \) and \( t^+ = F[t_1]^\perp...[t_k]^\perp \), then \((t^+)^\perp = \perp = t^\perp \).

If \( t = a_{t_1...t_k} \) with \( a : \sigma^k \rightarrow o \in \Sigma \) and \( t_i : o \) for all \( i \), then \( t^+ = a[t_1]^\perp...[t_k]^\perp \) and \((t^+)^\perp = a_{(t_1^+)\perp...}(t_k^+)\perp \). By induction hypothesis, for all \( i \) \((t_i^+)^\perp = t_i^\perp \), then \((t^+)^\perp = a_{t_1^\perp...t_k^\perp} = t^\perp \). \( \square \)

Lemma 26 (Label Conservation in Rewrite Rules). Given a term \( t : \sigma_1 \rightarrow ... \rightarrow \sigma_k \rightarrow o \in \mathcal{T}(\Sigma \sqcup \mathcal{N}) \), such that \( t = F_{x_1...x_k} \) with \( F \in \mathcal{N} \), and \( t \) is an IO-relevant redex. Note that \( t^+ = F[x_1]^\perp...[x_k]^\perp s_1^\perp...s_k^\perp \). If \( F_{x_1...x_k} \rightarrow e \in \mathcal{B} \), let \( t' = e_{[\gamma_i, x_i \mapsto s_i]} \) and \( s = e_{\Theta^+}^+ \gamma_i \sigma_i^\perp e_{\Theta^+}^+ [\gamma_i \mapsto e_{\Theta^+}^+] \).

We have \( s = (t')^+ \).

Proof of Lemma 26. Besides the labeling, by construction, \( s \) matches \((t')^+ \). Take a subterm \( e' \) of \( e \), if one can prove \( \Theta^+ \vdash e'_{[\gamma_i, x_i \mapsto s_i]} \sigma_i \), then one can prove \( \Theta^+ \vdash e' \sigma_i \), hence \( s \) is well labeled, therefore \( s = (t')^+ \). Then \( t^+ \Rightarrow^{tIO} (t')^+ \).

Given two terms \( t, t' \), we write \( t \Rightarrow^{tIO} t' \) if \( t' \) is obtained by applying in parallel all IO rewrite available in \( t \). Formally, we define it inductively: if \( t \) is an IO-relevant redex and \( t' \) is the term obtained by rewriting this redex then \( t \Rightarrow^{tIO} t' \). If \( t \) is not an IO redex and \( t = t_1 t_2 \) then \( t \Rightarrow^{tIO} t' \) if and only if:

- either there exists \( t'_1, t'_2 \) such that \( t_1 \Rightarrow^{tIO} t'_1 \) and \( t_2 \Rightarrow^{tIO} t'_2 \), and \( t' = t'_1 t'_2 \),
- or there exists \( t'_1 \) such that \( t_1 \Rightarrow^{tIO} t'_1 \) but no \( t'_2 \) such that \( t_2 \Rightarrow^{tIO} t'_2 \) and \( t' = t'_1 t_2 \),
- or there exists \( t'_1 \) such that \( t_2 \Rightarrow^{tIO} t'_2 \) but no \( t'_1 \) such that \( t_1 \Rightarrow^{tIO} t'_1 \) and \( t' = t_2 t'_1 \).

Notice that if such \( t' \) exists then it is unique, and it exists if and only if \( t \) contains a redex. The \( \Rightarrow^{tIO} \) relation is known as parallel rewrite, and from a term \( t : o \), the unique associated parallel derivation \( t \Rightarrow^{tIO} t_1 \Rightarrow^{tIO} t_2 \Rightarrow^{tIO} ... \) leads to the tree \( \|G_t\| \).

Lemma 27 (Coincidence of Parallel Derivation). Given a terms \( t \in \mathcal{T}(\Sigma \sqcup \mathcal{N}) \), and some conjunctive mappings \( \sigma_1, ..., \sigma_k \). There exists \( t' \in \mathcal{T}(\Sigma \sqcup \mathcal{N}) \) such that \( t \Rightarrow^{tIO} t' \), if and only if there exists \( t' \in \mathcal{T}(\Sigma' \sqcup \mathcal{N}') \) such that \( t' \in \sigma_1 ... \sigma_k \Rightarrow^{tIO} t' \). Furthermore, if it is true, then \( t' = (t')^+ \sigma_1 ... \sigma_k \).

Proof of Lemma 27. The first part of the result comes from the observation that \( t \) contains a redex if and only if \( t'^+ \sigma_1 ... \sigma_k \) contains a redex. We prove the second part by induction. If \( t \) is an IO-relevant redex, \( t'^+ \sigma_1 ... \sigma_k \) is too, and Lemma 25 proves the result. If \( t = t_1 t_2 \), \( t \) is not an IO-relevant redex a then \( t'^+ \sigma_1 ... \sigma_k = t_1'^+ \sigma_1 ... \sigma_k t_2'^+ \sigma_1 ... \sigma_k \) and \( t' \in \sigma_1 ... \sigma_k \) is not an IO-relevant redex. Assume that \( t \Rightarrow^{tIO} t' \) then:

- either there exists \( t'_1, t'_2 \) such that \( t_1 \Rightarrow^{tIO} t'_1 \) and \( t_2 \Rightarrow^{tIO} t'_2 \), and \( t' = t'_1 t'_2 \),
- or there exists \( t'_1 \) such that \( t_1 \Rightarrow^{tIO} t'_1 \) but no \( t'_2 \) such that \( t_2 \Rightarrow^{tIO} t'_2 \) and \( t' = t'_1 t_2 \),
- or there exists \( t'_1 \) such that \( t_2 \Rightarrow^{tIO} t'_2 \) but no \( t'_1 \) such that \( t_1 \Rightarrow^{tIO} t'_1 \) and \( t' = t_2 t'_1 \).

By induction hypothesis, \( t_i \Rightarrow^{tIO} t_{ij} \), if and only if \( t_{ij} \Rightarrow^{tIO} t_{ij}^+ \) for \( i \in \{1,2\} \), hence
• either there exists $t'_1, t'_2$ such that $t_1^{+\sigma_1, \ldots, \sigma_k} \Rightarrow_I t'_1$ and $t_2^{+\sigma_j} \Rightarrow_I t'_2$ for all $j$, and $(t')^{+\sigma_1, \ldots, \sigma_k} = (t'_1)^{+\sigma_1, \ldots, \sigma_k} (t'_2)^{+\sigma_j} ... (t'_2)^{+\sigma_j}$.

• or there exists $t'_1$ such that $t_1^{+\sigma_1, \ldots, \sigma_k} \Rightarrow_I t'_1$ but no $s'_2$ such that $t_2^{+\sigma_j} \Rightarrow_I s'_2$ for all $j$, and $(t')^{+\sigma_1, \ldots, \sigma_k} = (t'_1)^{+\sigma_1, \ldots, \sigma_k} (t_2)^{+\sigma_j} ... (t_2)^{+\sigma_j}$.

• or there exists $t'_2$ such that $t_2^{+\sigma_j} \Rightarrow_I t'_2$ but no $s'_1$ such that $t_1^{+\sigma_1, \ldots, \sigma_k} \Rightarrow_I s'_1$, and $(t')^{+\sigma_1, \ldots, \sigma_k} = (t_1)^{+\sigma_1, \ldots, \sigma_k} (t'_2)^{+\sigma_j} ... (t'_2)^{+\sigma_j}$.

Therefore, $t^{+\sigma_1, \ldots, \sigma_k} = (t')^{+\sigma_1, \ldots, \sigma_k}$.

□

Given a term $t : o$ let $t \Rightarrow_I t_1 \Rightarrow_I t_2 \Rightarrow_I \ldots$ be the parallel derivation associated to it. Thanks to Lemma [27] we know that the parallel derivation associated to $t^+$ is $t^+ \Rightarrow_I t_1^+ \Rightarrow_I t_2^+ \Rightarrow_I \ldots$, then $\|G'_t\|_I$ is the limit of $(t_i^+)^-$ as $(\|G'_t\|_I)^-$ is the limit of $(t_i^+)^- = t_i^-$. Then $\|G'_t\|_I = \|G_i\|_I$.

□

Proof of $\|G''\|_I = \|G'\|_I$. Take a term $t \in \mathcal{T}(\Sigma \uplus \mathcal{N})$ we define $\text{void}(t) \in \mathcal{T}(\Sigma \uplus \mathcal{N} \uplus \{\text{Void}\})$ as the set of terms obtained by substituting some redex $r$ in $t$ such that $\|G'_r\|_I = \bot$ by Void. From the definition comes that if $t' \in \text{void}(t)$ then $(t')^-$ = $t^-$.

Given a term $t \in \mathcal{T}(\Sigma \uplus \mathcal{N})$ and an IO derivation associated $t = t_1 \rightarrow_I t_2 \rightarrow_I \ldots$ in $G'$ we construct by induction an IO derivation in $G''$ $t = t'_1 \rightarrow_I t'_2 \rightarrow_I \ldots$ such that for all $t'_i \in \text{void}(t_i)$. The initial step is straightforward: $t \in \text{void}(t)$. Assume that $t_i' \in \text{void}(t_i)$, and assume that $t_i = C[F t_1 \ldots t_k]$ and $t_{i+1} = C[e_{t_i, t_1} \ldots t_k]$ with $F x_1 \ldots x_k \rightarrow e \in \mathcal{R}'$. If this redex is a subterm of another one that is transformed by Void in $t'_i$ then we just rewrite this void obtaining $t'_{i+1} = t'_i$ by induction hypothesis, we still have $t'_{i+1} \in \text{void}(t_{i+1})$. If this redex is not transformed in $t'_i$ then we rewrite this redex, and either $\|F t_1 \ldots t_k\|_I = \bot$, in which case the semantics associated contains no more transformation is added to create $t'_{i+1}$, in both cases $t'_{i+1} \in \text{void}(t_{i+1})$.

This result gives that $\|G'_t\|_I \subseteq \|G''\|_I$. Since $G''$ is obtained by from $G'$ changing some redex into other that will produce $\bot$, it is clear that $\|G''\|_I \subseteq \|G'_t\|_I$, then $\|G''\|_I = \|G'_t\|_I$.

□

Proof of $\|G''\|_I = \|G'\|_I$. We already know that $\|G''\|_I \subseteq \|G'\|_I$, we just have to show that for all $t$, if there is $\bot$ at node $u$ in $\|G'_t\|_I$ then there is $\bot$ at node $u$ in $\|G''\|_I$. We show this by induction on the size of $u$.

If $\|G'_t\|_O = \bot$. Then $\|G'_t\|_O = \|G_i\|_O = \bot$, hence $[t] = \bot$, hence the only derivation in $G''$ from $t$ is $t \rightarrow \text{Void} \rightarrow \text{Void} \rightarrow \ldots$, therefore $\|G''\|_I = \bot$. If $u = ju'$ then let $a$ be the terminal at the root of $\|G''\|_I$, then there exists an IO derivation $t \rightarrow^a t_1 \ldots t_k$, and $\|G''\|_I$ is equal to the subtree of $\|G''\|_I$ rooted at node $j$. Since $t \rightarrow^a t_1 \ldots t_k$, $\|G''\|_I$ is equal to the subtree of $\|G'_t\|_I$ rooted at node $j$ and by induction hypothesis, since there is $\bot$ at node $u'$ in $\|G'_t\|_I$, there is $\bot$ at node $u'$ in $\|G'_t\|_I$ hence there is $\bot$ at node $u$ in $\|G''\|_I$.
