## Abstract

The accurate prediction of high pressure phase equilibria is crucial for the development and the design of chemical engineering processes. Among them the modeling of complex systems, such as petroleum fluids with water, has become more and more important with the exploitation of reservoirs in extreme conditions. The aim of this work is to explore the capability of the NRTL-PR model to predict the solubility of solid polycyclic aromatic hydrocarbons in water. For this purpose, we first validate our methodology for fluid phase equilibria predictions of aromatic hydrocarbons and gas (CO<sub>2</sub>, C<sub>2</sub>H<sub>6</sub>) mixtures. Finally, we consider the prediction of the solid solubility of PAH in water, by fitting group parameters either only on SLE data or on both LLE and SLE data of aromatic hydrocarbon-water binary systems.

Keywords: solubility; solid-liquid equilibrium; EoS/G<sup>E</sup> approach; NRTL-PR model; polycyclic aromatic hydrocarbons; water.

## 1. Introduction

Polycyclic aromatic hydrocarbons (PAH) are very toxic substances which are often generated by human activities. They can be found in hydrocarbon-contaminated waste sites or in the sea after oil discharges by ships. They are also produced by offshore oil and gas exploration [1] and by several combustion processes [2,3], among others. Because these pollutants accumulate in soils and sediments and are persistent in the environment, it is crucial to understand their transport and transformation processes [4]. The solubility in water is an important transport property in the potential distribution of these compounds throughout the hydrologic system. Besides, the solubility is also necessary for the design of extraction processes of PAH with subcritical water [5,6] since it provides the extractability limit which can be used. Therefore, a good representation of solid-liquid equilibria in water-PAH mixtures is essential for many practical applications; but PAH are highly hydrophobic compounds and, consequently, an accurate prediction of their very low solubilities is difficult to obtain.

In literature, models proposed for the calculation of non-polar hydrophobic compound aqueous solubility are essentially based on empirical or semi-empirical equations, which do not allow accurate results at both low and high temperatures [7]. However, for some years, a few papers were concerned with the modeling of solid-liquid equilibria in water-PAH systems by means of equations of state and G<sup>E</sup> models. Fornari et al. [8] compared the accuracy of the original UNIFAC, the modified version of Dortmund and the A-UNIFAC models, the latter including association effects between groups, for the representation of the solubility of solid PAH in subcritical water. These

authors showed that the modified UNIFAC model gives a better prediction than the A-UNIFAC one, provided that the interaction parameters between water and aromatic groups are optimized by taking into account SLE data in the parameter fitting procedure. More recently, the CPA EoS, which adds an association term to the SRK equation of state, was applied by Oliveira et al. [9] to the modeling of the aqueous solubility of PAH. The major advantage of EoS based models, such as CPA, compared to  $G^E$  models, such as UNIFAC, is to allow solubility predictions in a wide range of temperature and pressure, and especially under high pressures. Oliveira et al. showed that a good representation of the solubility of PAH can be obtained by fitting the solvation parameter for each binary water-PAH system on SLE data.

The purpose of this work is to explore the capability of the NRTL-PR model [10,11] to predict solid-liquid equilibria (SLE) in water-PAH mixtures. This model is based on the EoS/ $G^E$  approach in which the Peng-Robinson equation of state is associated with the generalized NRTL excess Gibbs energy model [12]. In this formalism, binary interaction parameters are estimated from group contributions providing a totally predictive EoS. In order to validate the approach, the NRTL-PR model is first applied to the prediction of vapor-liquid equilibria (VLE) and of the solid solubility in supercritical fluids (SFE) of aromatic hydrocarbons with carbon dioxide or ethane. Then we investigate the capability of the model to predict both liquid-liquid equilibria (LLE) of aromatic hydrocarbons in water and the very low solubilities of PAH (SLE).

## 2. Modeling

### 2.1. Solid-fluid equilibrium

Solid-fluid equilibrium of binary mixtures of solvent(1)-PAH(2) is described assuming that the solid phase is pure PAH(2). The equilibrium condition for this component is thus written as:

$$g_2^S(T, P) = g_2^F(T, P, x) \quad (1)$$

where  $g_2^S(T, P)$  and  $g_2^F(T, P, x)$  are the molar Gibbs free energies of the pure solid (2) and of the solute in the fluid mixture, under the same temperature and pressure conditions; they are calculated by the following equations:

$$g_2^S(T, P) = g_2^S(T, P^{ref}) + v_2^S(P - P^{ref}) \quad (2)$$

$$g_2^F(T, P, x) = g_2^*(T, P^{ref}) + RT \ln \left[ \phi_2(T, P, x) \frac{P}{P^{ref}} x_2 \right] \quad (3)$$

with:  $P^{ref}$  a reference pressure,  $v_2^S$  the molar volume of the solid,  $g_2^*(T, P^{ref})$  the Gibbs free energy of pure compound 2 in the standard state and  $\phi_2(T, P, x)$  the fugacity coefficient in the fluid phase. The subcooled liquid pressure,  $P^{scl}$ , is chosen as the reference pressure, so that the term  $g_2^S(T, P^{ref})$  in Eq. (2) can be obtained from the Gibbs free energy of 2 as pure liquid,  $g_2^L(T, P^{scl})$ , considering the fusion properties:

$$g_2^S(T, P^{scl}) = g_2^L(T, P^{scl}) - \Delta_{fus}G_2(T, P^{scl}) \quad (4)$$

with:

$$g_2^L(T, P^{scl}) = g_2^*(T, P^{scl}) + RT \ln \phi_2(T, P^{scl}) \quad (5)$$

and:

$$\begin{aligned} \Delta_{fus}G_2(T, P^{scl}) = & \Delta_{fus}H_2(T_{m2}, P_0) \left[ 1 - \frac{T}{T_{m2}} \right] + \int_{T_{m2}}^T \Delta C_{P2}(T, P_0) dT \\ & - T \int_{T_{m2}}^T \Delta C_{P2}(T, P_0) \frac{dT}{T} + \Delta_{fus}v_2(T)(P^{scl} - P_0) \end{aligned} \quad (6)$$

where  $P_0$  is the atmospheric pressure,  $\Delta_{fus}H$  is the fusion enthalpy of the pure solute at its normal melting temperature  $T_m$ ,  $\Delta C_P$  is the difference in heat capacity at constant pressure between the subcooled liquid and solid forms of the pure solute at temperature  $T$  and  $\Delta_{fus}v$  is the fusion molar volume. As is usually done [13-15], in order to simplify Eq. (6),  $\Delta C_P$  is assumed to be independent of temperature and equal to the value at  $T_m$  so that  $\Delta_{fus}G_2(T, P^{scl})$  is given by:

$$\begin{aligned} \Delta_{fus}G_2(T, P^{scl}) = & \Delta_{fus}H_2(T_{m2}, P_0) \left[ 1 - \frac{T}{T_{m2}} \right] - \Delta C_{P2}(T_{m2}, P_0) \left[ T_{m2} - T + T \ln \frac{T}{T_{m2}} \right] \\ & + \Delta_{fus}v_2(T)(P^{scl} - P_0) \end{aligned} \quad (7)$$

The last two terms involving  $\Delta C_P$  and  $\Delta_{fus}v$  are neglected since they are usually small compared to the first one, especially for PAH; indeed, experimental values of  $\Delta C_P(T_m, P_0)$  are very low for these compounds [13,15]. Studies about the influence of  $\Delta C_P$  approximations on the estimation of solid solubility were reported in literature for several classes of components (see for example [13-15]). They showed that assuming  $\Delta C_P = 0$  in Eq. (7) for PAH doesn't lead to deteriorated predictions of solubilities and besides, Pappa et al. [15] recommended the use of this approximation. Furthermore, we checked that, for the set of solutes considered in this work, the term involving  $\Delta C_P$  was more than ten times lower than the fusion enthalpy term.

The introduction of Eqs. (2-7) in Eq. (1) leads to the following expression for the solubility of component 2:

$$x_2 = \frac{\phi_2(T, P^{scl})}{\phi_2(T, P^{scl}, x)} \frac{P^{scl}}{P} \exp \left[ \frac{v_2^S(P - P^{scl})}{RT} - \frac{\Delta_{fus}H_2(T_{m2}, P_0)}{R} \left( \frac{1}{T} - \frac{1}{T_{m2}} \right) \right] \quad (8)$$

In this work, the fugacity coefficients of component 2 as pure liquid,  $\phi_2(T, P)$ , and in the fluid mixture,  $\phi_2(T, P, x)$  are computed using the NRTL-PR model.

## 2.2. The NRTL-PR model

The NRTL-PR model is based on the Peng-Robinson equation of state [16]:

$$P = \frac{RT}{v-b} - \frac{a}{v^2 + 2bv - b^2} \quad (9)$$

in which the attractive term  $a$  is estimated using the EoS/ $G^E$  approach based on the generalized reference state proposed in [17]:

$$\alpha = \frac{a}{bRT} = \sum_i \alpha_i x_i - \frac{1}{0.53} \left[ \frac{g^E}{RT} - \sum_i x_i \ln \frac{r_i}{r} \right] \quad (10)$$

where  $b$  is the covolume,  $b = \sum_i x_i b_i$ ,  $r_i$  and  $r = \sum_i x_i r_i$  are the volume area factors characteristic of lattice fluid models and  $g^E$  is the excess Gibbs energy expressed, with the generalized NRTL equation [12], as:

$$g^E = RT \sum_i x_i \ln \frac{r_i}{r} + \sum_i x_i q_i \frac{\sum_j x_j q_j G_{ji} \Gamma_{ji}}{\sum_l x_l q_l G_{li}} \quad , \quad G_{ji} = \exp(-\alpha_0 \Gamma_{ji} / RT) \quad (11)$$

So that:

$$\alpha = \sum_i \alpha_i x_i - \frac{1}{0.53} \left[ \frac{g_{res}^E}{RT} \right] \quad , \quad g_{res}^E = \sum_i x_i q_i \frac{\sum_j x_j q_j G_{ji} \Gamma_{ji}}{\sum_l x_l q_l G_{li}} \quad (12)$$

In the above equation,  $\alpha_0$  is the non randomness factor ( $\alpha_0 = -1$ ) and  $q_i$  are the lattice fluid surface area parameters, estimated from the UNIFAC subgroups  $Q_k$ :

$$q_i = \sum_k v_{ik} Q_k \quad (13)$$

with  $v_{ik}$  the number of subgroup  $k$  in a molecule  $i$ . The group contribution and the surface area parameters  $Q_k$  considered in the NRTL-PR model are indicated in Table 1. It must be noted that no distinction is made between substituted single benzene ring carbons and fused-ring carbons. In Eqs. (11-12) the binary interaction parameters  $\Gamma_{ji}$  are computed by means of a group contribution [10] which makes the NRTL-PR equation a totally predictive model:

$$\Gamma_{ji} = \sum_K \theta_{iK} \sum_L (\theta_{jL} - \theta_{iL}) \Gamma_{LK} \quad , \quad \theta_{iK} = \sum_k v_{ik(K)} \frac{Q_k}{q_i} \quad \text{with : } \Gamma_{KK} = 0 \quad , \quad \Gamma_{KL} \neq \Gamma_{LK} \quad (14)$$

where  $\theta_{iK}$  is the probability that a contact from a molecule  $i$  involves a main group  $K$  and  $v_{ik(K)}$  is the number of subgroup  $k$  belonging to the main group  $K$  in a molecule  $i$ . The group interaction parameters  $\Gamma_{LK}$  depend on temperature with the following equation:

$$\Gamma_{LK} = \Gamma_{LK}^{(0)} + \Gamma_{LK}^{(1)} \left( \frac{T_0}{T} - 1 \right) \quad \text{with } T_0 = 298.15\text{K} \quad (15)$$

Finally, the model requires the estimation of pure component parameters: the attractive term  $a_i$  and the covolume  $b_i$  (necessary to calculate  $a_i$  in Eq. (12)) are estimated from the critical temperature and pressure,  $T_{ci}$  and  $P_{ci}$  respectively, by the formulae:

$$a_i = 0.4572 \frac{R^2 T_{ci}^2}{P_{ci}} f(T_r) \quad , \quad b_i = 0.0778 \frac{RT_{ci}}{P_{ci}} \quad (16)$$

where  $T_r$  is the reduced temperature,  $T_r = T/T_{ci}$ , and  $f(T_r)$  is the generalized Soave function [20]:

$$f(T_r) = \left[ 1 + m(1 - T_r^\gamma) \right]^2 \quad (17)$$

For hydrocarbons and non associating compounds, we used the original Soave function [21], corresponding to  $\gamma = 0.5$ , and the parameter  $m$  correlated to the acentric factor  $\omega$  through the generalized expression proposed by Robinson and Peng [22]:

$$\begin{cases} m = 0.37464 + 1.54226\omega - 0.26992\omega^2 & \text{if } \omega < 0.49 \\ m = 0.379642 + 1.48503\omega - 0.164423\omega^2 + 0.016666\omega^3 & \text{if } \omega \geq 0.49 \end{cases} \quad (18)$$

On the other hand, for associating compounds, the  $\gamma$  and  $m$  parameters were fitted on saturation properties as proposed in [20], which allows highly improved vapor pressure representations. For water the fitted values are :  $\gamma = 0.65$ ,  $m = 0.6864$ .

With the NRTL-PR equation, the fugacity coefficient of a component  $i$  is given by the following relation:

$$\ln \varphi_i = -\ln Z(1-\eta) + (Z-1) \frac{1}{b} \left( \frac{\partial nb}{\partial n_i} \right)_{n_j} - \frac{1}{2\sqrt{2}} \ln \left( \frac{1+(1+\sqrt{2})\eta}{1+(1-\sqrt{2})\eta} \right) \left( \frac{\partial n\alpha}{\partial n_i} \right)_{T,n_j} \quad (19)$$

where  $Z$  is the compressibility factor,  $\eta = b/v$  and :

$$\left( \frac{\partial n\alpha}{\partial n_i} \right)_{T,n_j} = \frac{a_i}{b_i RT} - \frac{1}{0.53} \left( \frac{\partial ng_{res}^E}{\partial n_i} \right)_{T,n_j} \quad (20)$$

### 3. Results

The set of solvents and PAH considered in this work is given in Table 2, together with the values of the pure component properties. For PAH, the normal melting temperatures,  $T_m$ , and fusion enthalpies at melting point,  $\Delta_{fus}H$ , as well as the solid volumes,  $v_2^s$ , were taken from literature.

#### 3.1. Solubility of PAH in supercritical fluids

As already mentioned in the introduction, PAH are highly hydrophobic compounds. Therefore, an accurate representation of their very low solubilities in water is very difficult to obtain. As a

consequence, water-PAH systems are not the most appropriate to check if a model is able to predict correctly solid-fluid equilibria. Thus, in order to validate the approach proposed in section 2, we first considered the solubility of PAH in supercritical fluids; indeed, as can be seen in Tables 3 and 4 for CO<sub>2</sub> and ethane, the experimental values are about three orders of magnitude higher than those in liquid water.

The calculation of solid-fluid equilibria of CO<sub>2</sub>-PAH and ethane-PAH mixtures with the NRTL-PR model (Eq. 12) requires fitting the EoS binary parameters  $\Gamma_{aromatic,CO_2}$  and  $\Gamma_{aromatic,C_2H_6}$  (Eqs. 14, 15) taking into account simultaneously VLE and SFE data. Results thus obtained on PAH solubilities in supercritical carbon dioxide and ethane are reported respectively in Tables 3 and 4. For almost all mixtures, mean deviations are smaller than 30%, except for some heavier compounds involving at least three benzene rings and exhibiting lower solubilities.

Figure 1 illustrates the prediction of solubilities, with respect to pressure, for the most representative systems in the range of experimental temperature. It can be seen that for mixtures of naphthalene, pyrene, phenanthrene, fluorene and biphenyl with CO<sub>2</sub>, as well as naphthalene with ethane, predictions with the NRTL-PR model are in very good agreement with experimental data. Figure 1d, concerning anthracene, pyrene and phenanthrene with supercritical ethane, shows that, despite higher deviations, a satisfactory representation of the solubilities is obtained. For measurements made in the vicinity of the mixture lower critical endpoint (Fig. 1a), the strong variation of the solubility with respect to pressure and the retrograde solubility phenomenon are accurately described.

To ensure that VLE predictions were not deteriorated by considering SFE data during parameter fitting procedure, we represent in Fig. 2 VLE for aromatic hydrocarbons. Figures 2a and 2b for CO<sub>2</sub>-benzene and ethane-toluene highlight that results are similar to those previously published [11] for single benzene ring molecules. Furthermore, as shown in Figs. 2c and 2d, satisfactory phase envelopes are calculated for gas-PAH systems, although experimental data are not available in the whole composition range.

We can therefore conclude that the NRTL-PR model is able to accurately estimate VLE of aromatic hydrocarbons and solubilities of PAH in solvents with the same set of parameters.

### ***3.2. Application to the solubility of PAH in liquid water***

The calculation of SLE of water-PAH mixtures with the NRTL-PR model (Eq. 12) also requires the values of the EoS binary parameters  $\Gamma_{aromatic,H_2O}$  and  $\Gamma_{H_2O,aromatic}$  (Eqs. 14, 15).

In a first step, the modeling was performed by using the parameter values previously obtained [11] by correlating LLE for a set of 23 binary mixtures of aromatic hydrocarbons with water; results obtained in this case were rather satisfactory with relative deviations on the mole fractions of 12.43% for water in the organic phase and 21.70% for hydrocarbons in the aqueous phase. Figure 3 illustrates typical LLE behavior for benzene and m-xylene in water with the NRTL-PR [LLE] using LLE parameters. As expected, the prediction of SLE using these parameters was not satisfactory.

In order to check the capability of the model to correlate water-PAH SLE, the EoS binary parameters  $\Gamma_{LK}$  and  $\Gamma_{KL}$  were fitted to SLE data only; deviations  $\Delta x_2/x_2\%$  [SLE] thus obtained are given in Table 5 and solubility curves for water-acenaphthene and water-phenanthrene are shown in Fig. 4. Qualitatively good results are obtained, with nevertheless an overestimation of solubilities below  $10^{-7}$ .

Finally, the whole set of LLE and SLE data was correlated with the NRTL-PR equation. Deviations  $\Delta x_2/x_2\%$  [LLE+SLE] thus obtained are given in Table 5 and LLE and SLE predictions are illustrated in Figs. 5a, 5b, 6a and 6b, respectively, for toluene, p-xylene, naphthalene and fluorene in water. For systems exhibiting LLE, it appears that the global modeling does not affect the prediction of the organic phase, while mole fractions in the aqueous phase are slightly underestimated. In the case of water-PAH systems, the global modeling allows predicting more accurate solubilities for binary mixtures with the highest experimental values ( $>10^{-7}$ ).

#### 4. Conclusion

In this paper, we explored the capability of the NRTL-PR model to predict solid-liquid equilibria in water-PAH mixtures. For this purpose, we first considered high pressure phase equilibria of aromatic hydrocarbons in carbon dioxide or ethane, since solid solubilities of PAH are higher than in water. We showed that it is possible to accurately predict simultaneously VLE and SFE in those supercritical fluids, provided that all kinds of data are accounted for during the group contribution parameters fitting procedure.

We then applied our methodology to PAH-water systems. If parameters are fitted only on SLE data, satisfactory results were obtained for all the compounds, especially in the lowest solubility range. The consideration of both LLE and SLE data leads to an unmodified representation of the organic phase and a slight underestimation of aqueous phase solubilities, compared to our previous results concerning aromatic hydrocarbons-water mixtures; more accurate solubility predictions are obtained for solid PAH with the highest experimental values.

## List of tables

### Table 1

Group contribution of the NRTL-PR model and surface area parameters  $Q_k$  considered.

### Table 2

Properties of pure compounds. Critical temperature,  $T_c$ , and pressure,  $P_c$ , acentric factor,  $\omega$ , melting temperature,  $T_m$ , normal fusion enthalpy,  $\Delta_{fus}H$ , and solid molar volume,  $v^S$ .

### Table 3

Modeling of solid PAH in supercritical carbon dioxide by means of the NRTL-PR model. Number of SFE data points,  $Np$ , percent deviations,  $\Delta x_2/x_2\%$ , on the solubility of PAH using parameters fitted on VLE+SFE data;  $x_2^*$  is the range of experimental solubilities and Ref. is the reference of experimental SFE data.

### Table 4

Modeling of solid PAH in supercritical ethane by means of the NRTL-PR model. Number of SFE data points,  $Np$ , percent deviations,  $\Delta x_2/x_2\%$ , on the solubility of PAH using parameters fitted on VLE+SFE data;  $x_2^*$  is the range of experimental solubilities and Ref. is the reference of experimental SFE data.

### Table 5

Modeling of solid PAH in water by means of the NRTL-PR model. Number of SLE data points,  $Np$ , percent deviations,  $\Delta x_2/x_2\%$ , on the solubility of PAH using parameters fitted on SLE data ( $\Delta x_2/x_2\%$  [SLE]) or on LLE+SLE data ( $\Delta x_2/x_2\%$  [LLE+SLE]);  $x_2^*$  is the range of experimental solubilities and Ref. is the reference of experimental SLE data.

**Table 1**Group contribution of the NRTL-PR model and surface area parameters  $Q_k$  considered.

<i>Main Groups K</i>	<i>Subgroups k</i>	$Q_k$	<i>Ref.</i>
Alkanes	CH <sub>3</sub>	0.848	[18]
	CH <sub>2</sub>	0.540	[18]

2,7-dimethyl naphthalene	10	308-328	88-249	13.20	$7.4 \times 10^{-4} - 1.2 \times 10^{-2}$	[70]
anthracene	282	293-368	69-1156	38.94	$3.3 \times 10^{-6} - 4.4 \times 10^{-4}$	[39,71-78]
phenanthrene	306	303-343	78-414	24.31	$2.1 \times 10^{-5} - 4.1 \times 10^{-3}$	[38,39,43,47,71,73,76,79-81]
acenaphthene	45	308-348	121-356	53.55	$1.3 \times 10^{-3} - 1.4 \times 10^{-2}$	[82]
fluorene	187	303-343	70-483	16.81	$1.0 \times 10^{-5} - 9.2 \times 10^{-3}$	[39,76,80,83]
fluoranthene	73	308-348	86-355	56.76	$9.1 \times 10^{-6} - 1.5 \times 10^{-3}$	[79,82]
pyrene	254	308-373	80-483	25.69	$2.7 \times 10^{-6} - 1.6 \times 10^{-3}$	[39,71,84,85]

**Table 4**

Modeling of solid PAH in supercritical ethane by means of the NRTL-PR model. Number of SFE data points,  $N_p$ , percent deviations,  $\Delta x_2/x_2\%$ , on the solubility of PAH using parameters fitted on VLE+SFE data;  $x_2^*$  is the range of experimental solubilities and Ref. is the reference of experimental SFE data.

<i>Compounds</i>	<i>N<sub>p</sub></i>	<i>T<sub>range</sub>(K)</i>	<i>P<sub>range</sub> (bar)</i>	<i>Δ x<sub>2</sub> / x<sub>2</sub> %</i>	<i>x<sub>2</sub><sup>*</sup></i>	<i>Ref.</i>
biphenyl	10	308-318	70-300	29.30	$1.0 \times 10^{-2} - 6.2 \times 10^{-2}$	[86]
triphenyl methane	20	303-323	50-400	39.69	$2.4 \times 10^{-4} - 5.6 \times 10^{-3}$	[39]
naphthalene	69	293-328	40-360	23.95	$1.8 \times 10^{-4} - 1.4 \times 10^{-1}$	[39,86]
anthracene	87	313-343	100-500	50.20	$4.2 \times 10^{-5} - 4.2 \times 10^{-4}$	[39,71]
phenanthrene	83	303-328	50-450	36.88	$2.0 \times 10^{-4} - 1.1 \times 10^{-2}$	[39,71,86]
pyrene	15	333	100-350	40.15	$2.5 \times 10^{-4} - 1.2 \times 10^{-3}$	[71]

**Table 5**

Modeling of solid PAH in water by means of the NRTL-PR model. Number of SLE data points,  $N_p$ , percent deviations,  $\Delta x_2/x_2\%$ , on the solubility of PAH using parameters fitted on SLE data ( $\Delta x_2/x_2\%$  [SLE]) or on LLE+SLE data ( $\Delta x_2/x_2\%$  [LLE+SLE]);  $x_2^*$  is the range of experimental solubilities and Ref. is the reference of experimental SLE data.

<i>Compounds</i>	<i>N<sub>p</sub></i>	<i>T<sub>range</sub>(K)</i>	$\Delta x_2/x_2\%$ [SLE]	$\Delta x_2/x_2\%$ [LLE+SLE]	$x_2^*$	<i>Ref.</i>
Biphenyl	40	273-337	65.59	39.50	$3.1 \times 10^{-7} - 5.4 \times 10^{-6}$	[95-105]
Naphthalene	97	273-348	52.18	26.77	$1.7 \times 10^{-6} - 4.4 \times 10^{-5}$	[32,95,96,98-102,104,105,107-120]
2-methyl naphthalene	2	298	40.31	10.16	$3.1 \times 10^{-6} - 3.2 \times 10^{-6}$	[100,102]
2,3-dimethyl naphthalene	2	298	64.60	38.10	$2.3 \times 10^{-7} - 3.5 \times 10^{-7}$	[100,102]
2,6-dimethyl naphthalene	2	298	51.96	18.24	$1.5 \times 10^{-7} - 2.3 \times 10^{-7}$	[100,102]
Anthracene	96	273-483	41.98	201.69	$1.0 \times 10^{-9} - 2.2 \times 10^{-4}$	[95,102,105,111-113,116,118,123-128]
Phenanthrene	54	273-363	53.34	237.25	$3.9 \times 10^{-8} - 3.3 \times 10^{-6}$	[96,100,102,104,105,111,118,122,128-131]
Acenaphthene	23	273-348	39.19	12.79	$1.7 \times 10^{-7} - 5.0 \times 10^{-6}$	[97,100,102,104,105,125,128]
Fluorene	34	273-383	10.09	50.86	$7.2 \times 10^{-8} - 1.6 \times 10^{-5}$	[102,105,112,113,128,132]

## List of figures

**Figure 1.** SFE of gas–PAH systems using the NRTL-PR model.

(a) CO<sub>2</sub>(1) – naphthalene(2) at (□, —) 308K, (◇, —) 318K and (Δ, ----) 328K. (b) (□, —) CO<sub>2</sub>(1) – pyrene(2), (◇, —) CO<sub>2</sub>(1) – phenanthrene(2), (Δ, ----) CO<sub>2</sub>(1) – fluorene(2) and (○, - · - · -) CO<sub>2</sub>(1) – biphenyl(2) at 308K. (c) C<sub>2</sub>H<sub>6</sub>(1) – naphthalene(2) at (□, —) 298K and (◇, —) 308K. (d) (□, —) C<sub>2</sub>H<sub>6</sub>(1) – anthracene(2), (◇, —) C<sub>2</sub>H<sub>6</sub>(1) – pyrene(2) and (Δ, ----) C<sub>2</sub>H<sub>6</sub>(1) – phenanthrene(2) at 333K. [Experimental data references given in Tables 3 and 4]

**Figure 2.** VLE of gas–aromatic hydrocarbon systems using the NRTL-PR model.

(a) CO<sub>2</sub>(1) – benzene(2) at (□, —) 273K [87], (◇, —) 313K [88], (Δ, ----) 347K [89] and (○, - · - · -) 414K [90]. (b) C<sub>2</sub>H<sub>6</sub>(1) – toluene(2) [91] at (□, —) 313K, (◇, —) 393K and (Δ, ----) 473K. (c) CO<sub>2</sub>(1) – naphthalene(2) at (□, —) 373K [92-94], (◇, —) 403K [94] and (Δ, ----) 430K [94]. (d) (□, —) CO<sub>2</sub>(1) – biphenyl(2) [92] and (◇, —) CO<sub>2</sub>(1) – phenanthrene(2) [93] at 423K.

**Figure 3.** LLE of water–aromatic hydrocarbon systems using NRTL-PR [LLE] (—) parameters: mole fraction of aromatic hydrocarbon in the aqueous phase  $x_2^{Aq}$  (◇) and of water in the hydrocarbon phase  $x_1^{Org}$  (□).

(a) Water(1) – benzene(2) [133]: calculations performed under atmospheric pressure. (b) Water(1) – m-xylene(2) [134]: calculations performed under P = 10 MPa.

**Figure 4.** SLE of water–aromatic hydrocarbon systems using NRTL-PR [SLE] (—) parameters: solubility of PAH in water  $x_2$  (◇) under atmospheric pressure.

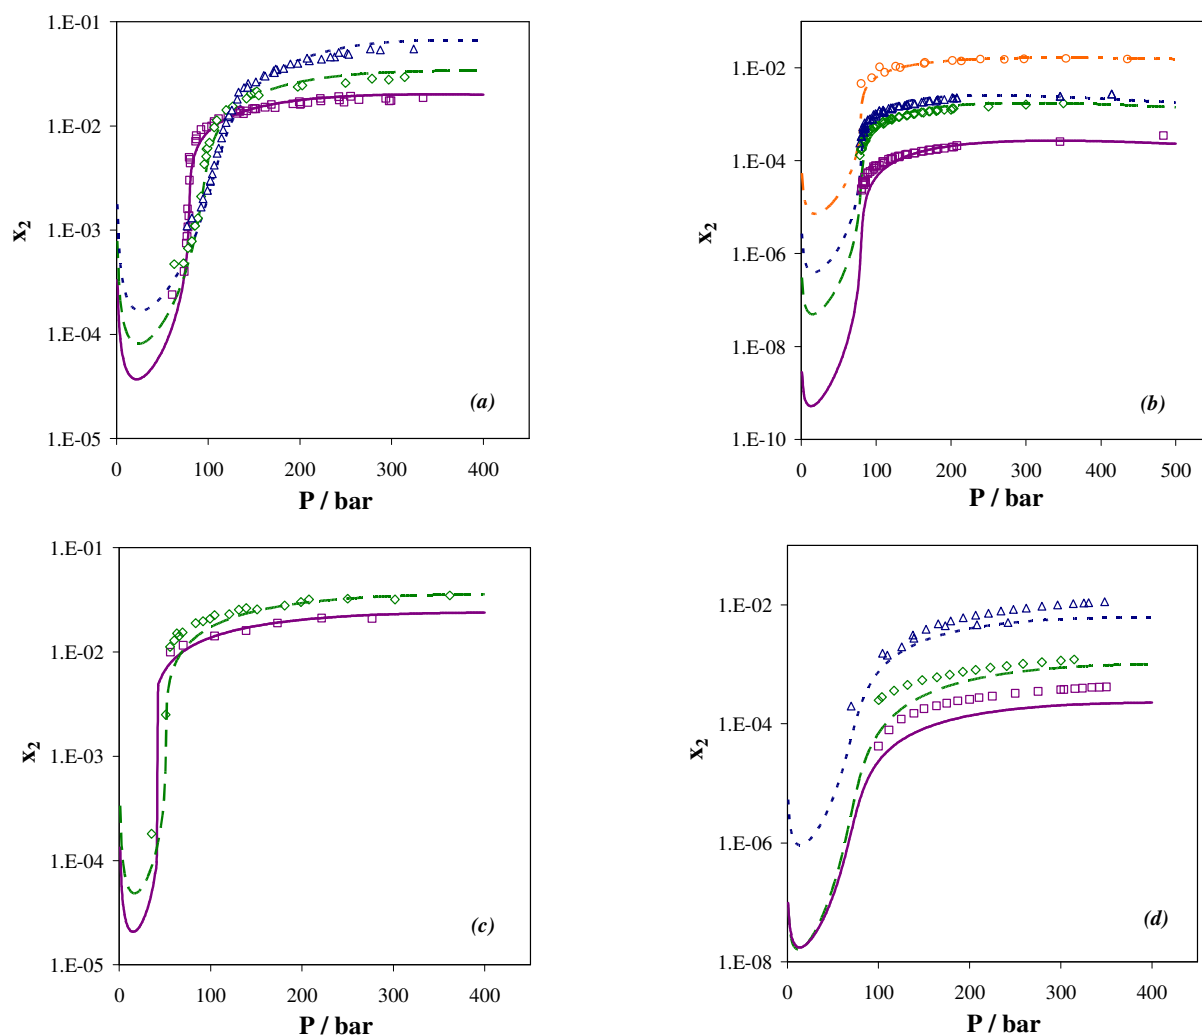

(a) Water(1) – acenaphthene(2). (b) Water(1) – phenanthrene(2). [Experimental data references given in Table 5]

**Figure 5.** LLE of water–aromatic hydrocarbon systems using NRTL-PR [LLE] (—) or [LLE+SLE] (—) parameters: mole fraction of aromatic hydrocarbon in the aqueous phase  $x_2^{Aq}$  (◇) and of water in the hydrocarbon phase  $x_1^{Org}$  (□) under atmospheric pressure.

(a) Water(1) – toluene(2) [135]. (b) Water(1) – p-xylene(2) [134].

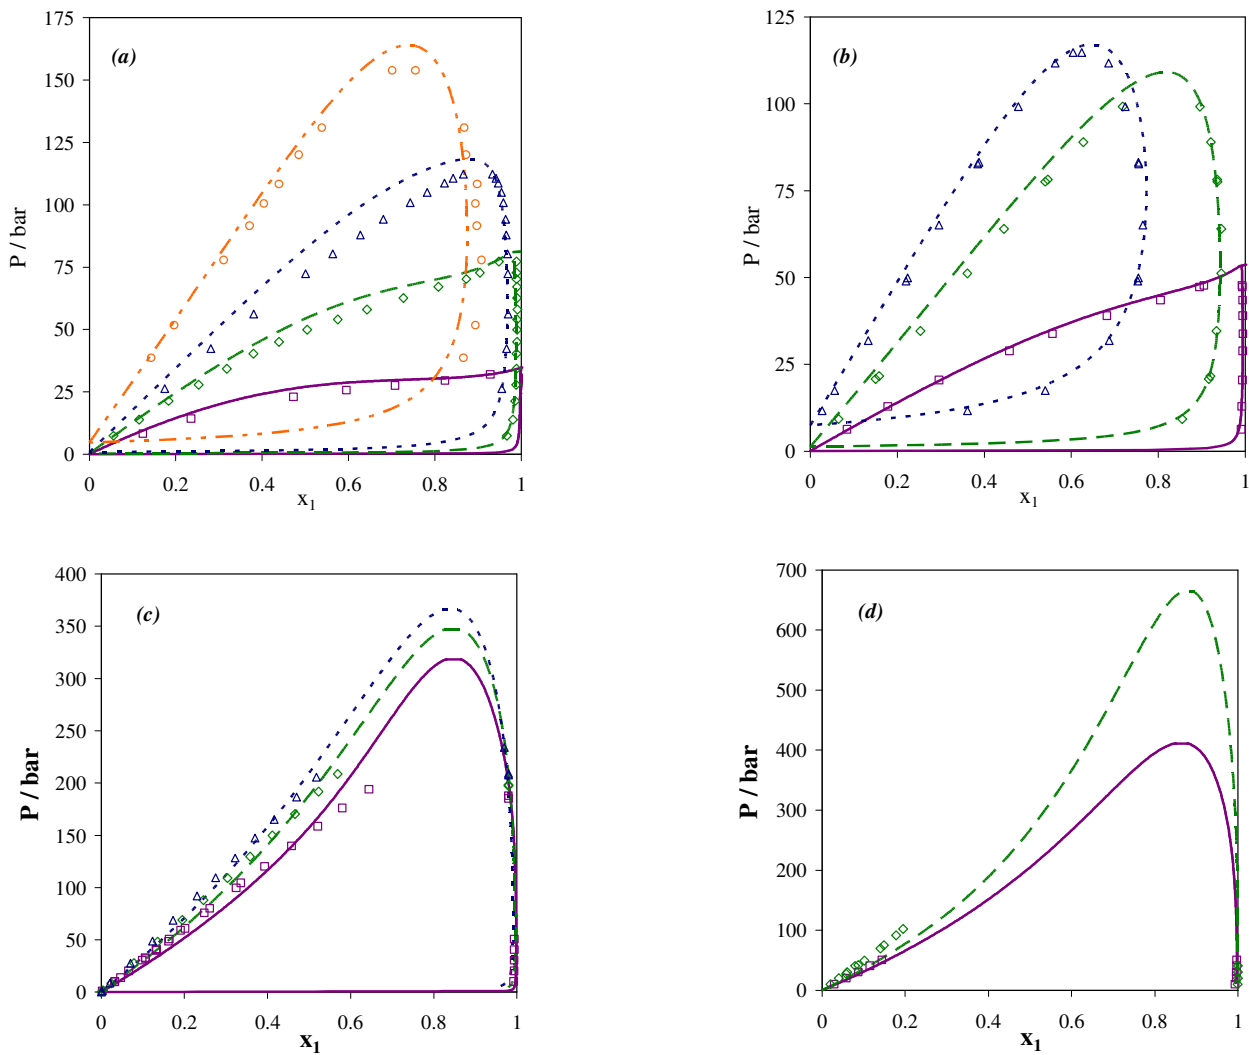

**Figure 6.** SLE of water–aromatic hydrocarbon systems using NRTL-PR [SLE] (—) or [LLE+SLE] (—) parameters: solubility of PAH in water  $x_2$  (◇).

(a) Water(1) – naphthalene(2): calculations performed under atmospheric pressure. (b) Water(1) – fluorene(2): calculations performed under P = 5 MPa. [Experimental data references given in Table 5]

**Figure 1.** SFE of gas–PAH systems using the NRTL-PR model.

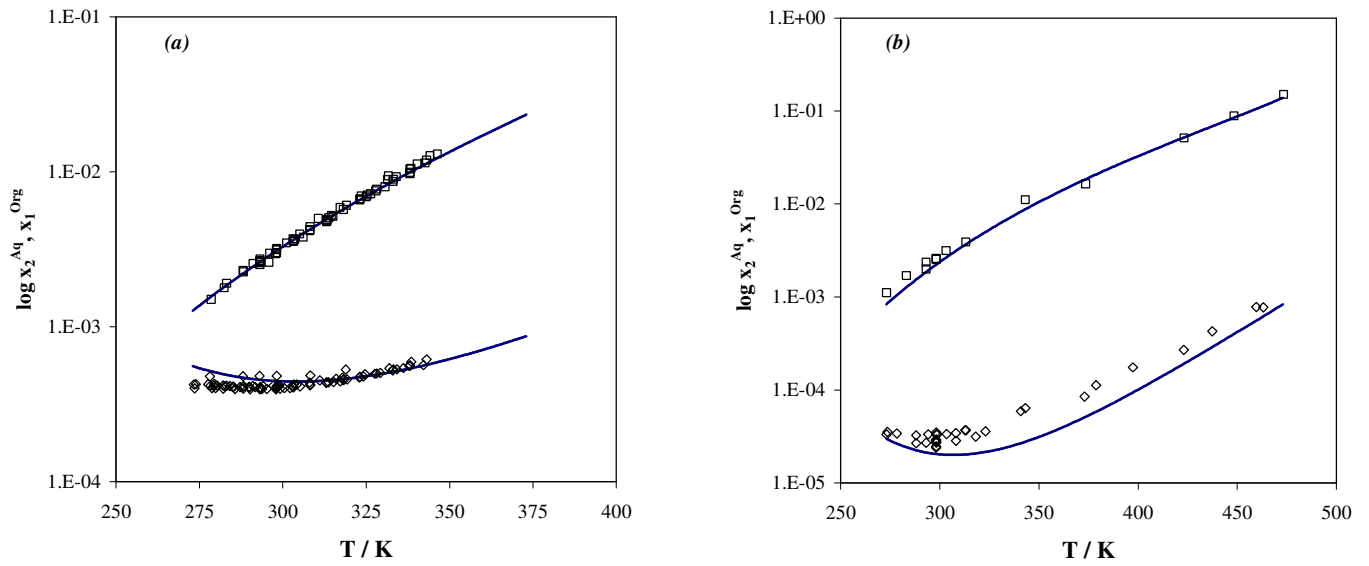

(a)  $\text{CO}_2(1)$  – naphthalene(2) at  $(\square, \text{—})$  308K,  $(\diamond, \text{--})$  318K and  $(\Delta, \text{---})$  328K. (b)  $(\square, \text{—})$   $\text{CO}_2(1)$  – pyrene(2),  $(\diamond, \text{--})$   $\text{CO}_2(1)$  – phenanthrene(2),  $(\Delta, \text{---})$   $\text{CO}_2(1)$  – fluorene(2) and  $(\circ, \text{---})$   $\text{CO}_2(1)$  – biphenyl(2) at 308K. (c)  $\text{C}_2\text{H}_6(1)$  – naphthalene(2) at  $(\square, \text{—})$  298K and  $(\diamond, \text{--})$  308K. (d)  $(\square, \text{—})$   $\text{C}_2\text{H}_6(1)$  – anthracene(2),  $(\diamond, \text{--})$   $\text{C}_2\text{H}_6(1)$  – pyrene(2) and  $(\Delta, \text{---})$   $\text{C}_2\text{H}_6(1)$  – phenanthrene(2) at 333K. [Experimental data references given in Tables 3 and 4]

**Figure 2.** VLE of gas-aromatic hydrocarbon systems using the NRTL-PR model.

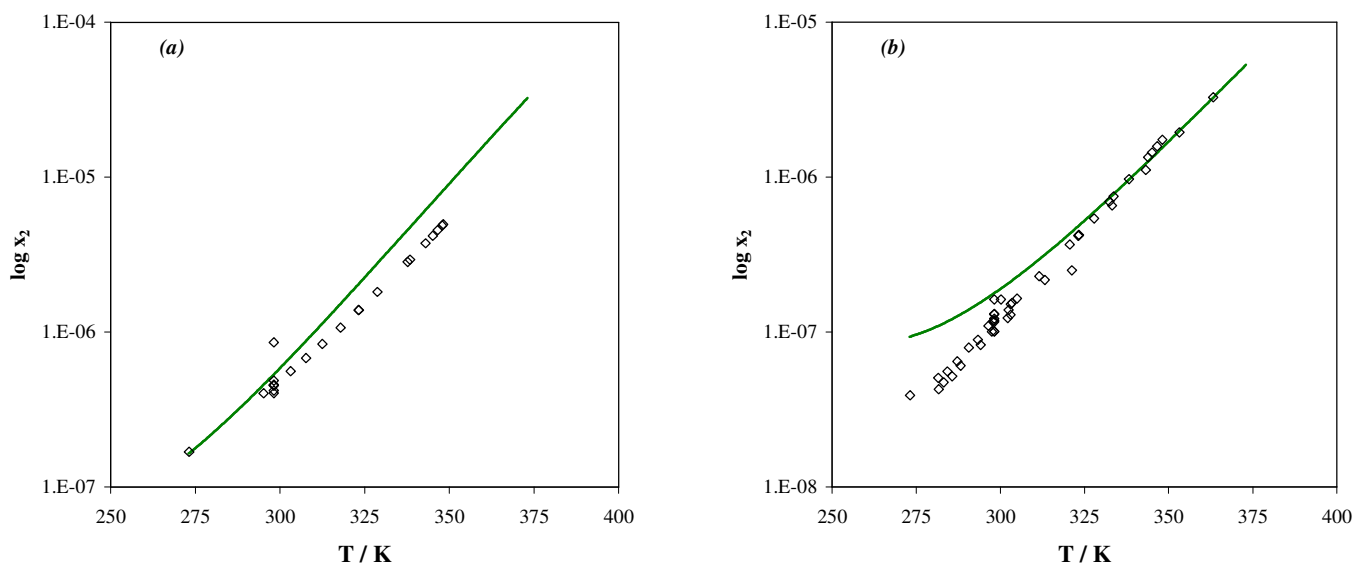

(a)  $\text{CO}_2(1)$  – benzene(2) at ( $\square$ , —) 273K [87], ( $\diamond$ , —) 313K [88], ( $\Delta$ , ---) 347K [89] and ( $\circ$ , - - - -) 414K [90]. (b)  $\text{C}_2\text{H}_6(1)$  – toluene(2) [91] at ( $\square$ , —) 313K, ( $\diamond$ , —) 393K and ( $\Delta$ , ---) 473K. (c)  $\text{CO}_2(1)$  – naphthalene(2) at ( $\square$ , —) 373K [92-94], ( $\diamond$ , —) 403K [94] and ( $\Delta$ , ---) 430K [94]. (d) ( $\square$ , —)  $\text{CO}_2(1)$  – biphenyl(2) [92] and ( $\diamond$ , —)  $\text{CO}_2(1)$  – phenanthrene(2) [93] at 423K.

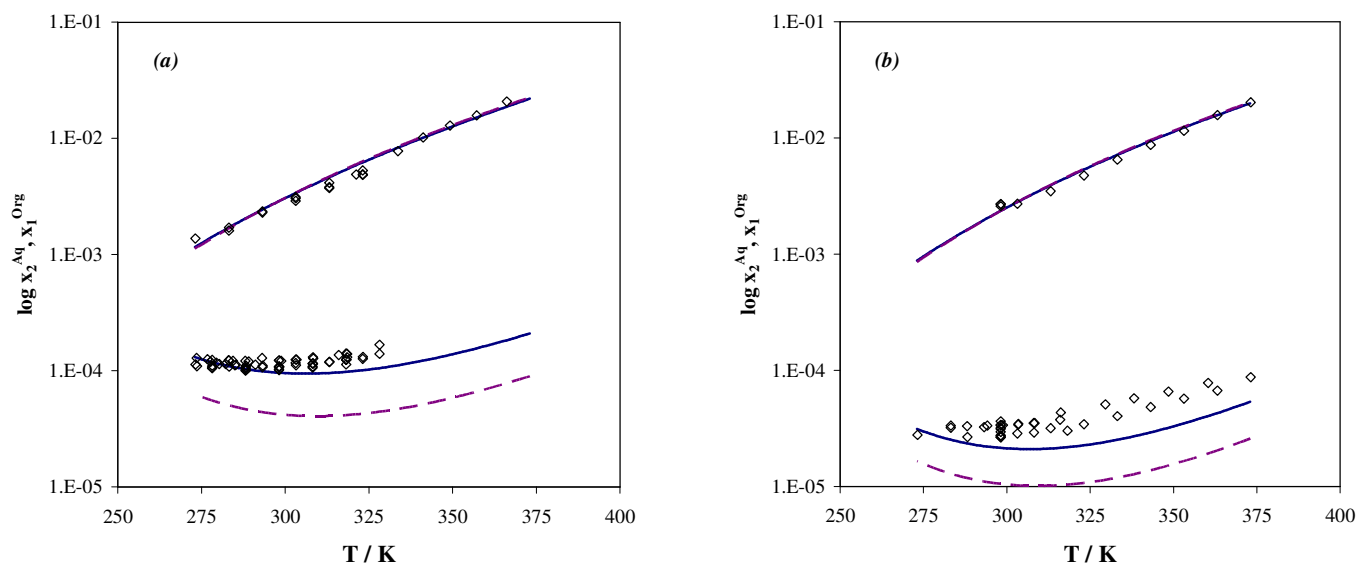

**Figure 3.** LLE of water–aromatic hydrocarbon systems using NRTL-PR [LLE] (—) parameters: mole fraction of aromatic hydrocarbon in the aqueous phase  $x_2^{Aq}$  ( $\diamond$ ) and of water in the hydrocarbon phase  $x_1^{Org}$  ( $\square$ ).

(a) Water(1) – benzene(2) [133]: calculations performed under atmospheric pressure. (b) Water(1) – m-xylene(2) [134]: calculations performed under P = 10 MPa.

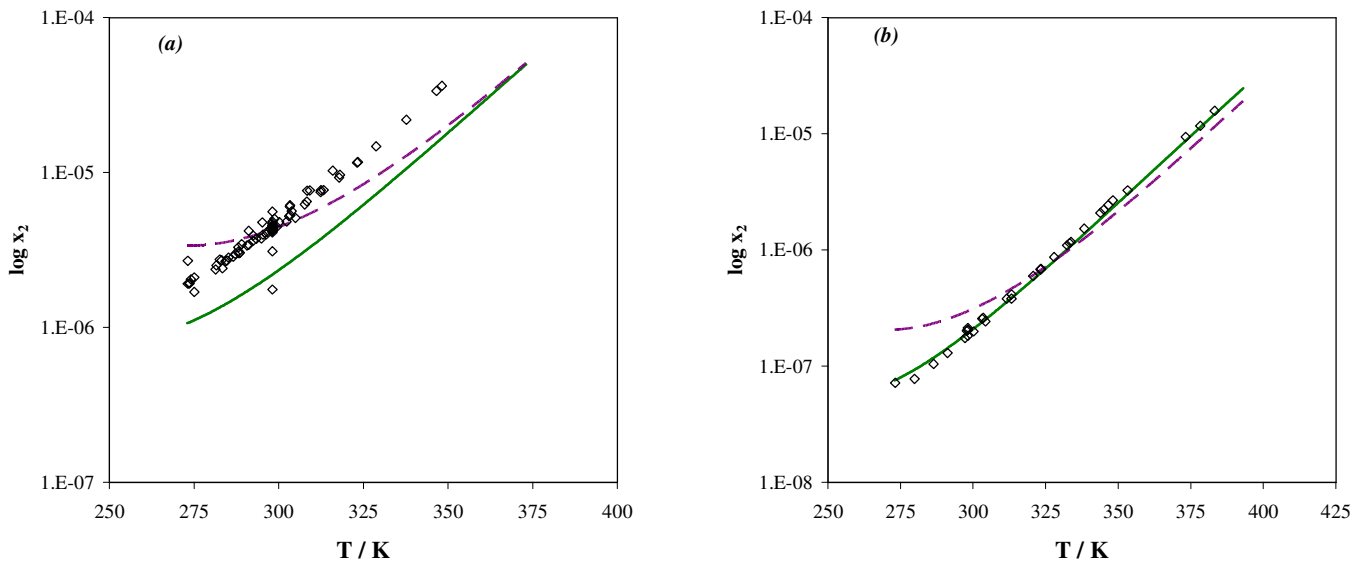

**Figure 4.** SLE of water–aromatic hydrocarbon systems using NRTL-PR [SLE] (—) parameters: solubility of PAH in water  $x_2$  ( $\diamond$ ) under atmospheric pressure.

(a) Water(1) – acenaphthene(2). (b) Water(1) – phenanthrene(2). [Experimental data references given in Table 5]

**Figure 5.** LLE of water–aromatic hydrocarbon systems using NRTL-PR [LLE] (—) or [LLE+SLE] (---) parameters: mole fraction of aromatic hydrocarbon in the aqueous phase  $x_2^{Aq}$  ( $\diamond$ ) and of water in the hydrocarbon phase  $x_1^{Org}$  ( $\square$ ) under atmospheric pressure.

(a) Water(1) – toluene(2) [135]. (b) Water(1) – p-xylene(2) [134].

**Figure 6.** SLE of water–aromatic hydrocarbon systems using NRTL-PR [SLE] (—) or [LLE+SLE] (---) parameters: solubility of PAH in water  $x_2$  ( $\diamond$ ).

(a) Water(1) – naphthalene(2): calculations performed under atmospheric pressure. (b) Water(1) – fluorene(2): calculations performed under  $P = 5$  MPa. [Experimental data references given in Table 5]
