Abstract. In the setting of classical first-order logic with inductive predicates, two kinds of sequent-based induction reasoning are distinguished: cyclic and structural. Proving their equivalence is of great theoretical and practical interest for the automated reasoning community. In [3,4], it has been shown how to transform any structural proof developed with the LKID system into a cyclic proof using the CLKID system. However, the inverse transformation was only conjectured. We provide a simple procedure that performs the inverse transformation for an extension of LKID with explicit induction rules issued from the structural analysis of CLKID proofs, then establish the equivalence of the two systems. This result is further refined for an extension of LKID with Noetherian induction rules. We show that Noetherian induction subsumes the two kinds of reasoning. This opens the perspective for building new effective induction proof methods and validation techniques supported by (higher-order) certification systems integrating the Noetherian induction principle, like Coq.

1 Introduction

( Mathematical) induction reasoning is known to be one of the most effective reasoning methods. Its distinctive feature is the use, during the proof process, of induction hypotheses representing ‘not yet proved’ formulas.

The induction hypotheses can be defined before their use, by explicit induction schemas that can be directly embedded in inference systems using explicit induction rules. On the other hand, the induction hypotheses can also be defined by need, at the moment of their use. In this case, the induction reasoning is schemata-free but should be performed at the proof level because the induction hypotheses can be (instances of) formulas positioned anywhere in the derivation.

The relation between the two kinds of induction reasoning was previously studied for Gentzen-style μ-calculus proof systems and proved equivalent, i.e., the proofs are convertible between systems. In [8], the explicit induction proofs are finite and the induction rules locally implement the Noetherian induction principle. The second kind of reasoning is captured by ω-regular proof trees that are finitely represented by stopping the development of the (sub-)derivations
for nodes labelled with formulas already encountered in the derivation. The soundness of the method is ensured if the cyclic induction reasoning associated to each strongly connected component of the proof graph is well-founded.

We are interested to extrapolate the equivalence result for sequent-based systems that extend the Gentzen’s LK system [6] to reason on inductively defined predicates [1]. We focus on two representative systems, proposed by Brotherston [3,4]: i) the LKID structural system that integrates induction rules generalizing Noetherian induction reasoning by the means of schemas issued from the recursion analysis of (mutually defined) inductive predicates, and ii) the CLKIDω cyclic system, issued from LKID by replacing the induction rules with case-split rules. A main result of [3,4] is that any LKID proof is convertible into a CLKIDω proof. However, the conversion in the other direction is only conjectured.

In this paper, we present a procedure that builds dynamically explicit induction schemas from the structural analysis of CLKIDω proofs. Firstly, we show the equivalence between CLKIDω and an extension of LKID, denoted by LKID∼, with induction rules that embed cyclic reasoning from existing CLKIDω proofs. The procedure is further refined to build Noetherian induction schemas from the productions defining new inductive predicate symbols attached to strongly connected components. LKID and CLKIDω, extended to deal with the new symbols, are shown equivalent. We conclude that Noetherian induction is sufficient to represent the structural and cyclic induction reasoning in this setting. Aside the theoretical and technical interests, this result can help developing i) effective sequent-based induction methods that combine the advantages of the two kinds of reasoning, and ii) automated techniques for their validation, supported by (higher-order) certification environments integrating the Noetherian induction principle, like Coq [11].

The paper is structured in 6 sections. Section 2 gives the preliminaries for reasoning with sequent-based inference systems for classical first-order logic (FOL) with inductively defined predicates (FOLID), then presents the CLKIDω and LKID systems. The structural analysis of cyclic proofs is explained in Section 3. LKID∼ is introduced in Section 4. The extension of LKID with Noetherian induction rules, denoted by LKID=e, is presented in Section 5, as well as the procedure transforming CLKIDω proofs into LKID=e proofs. As a running example, we consider ‘P and Q’ [12]. The conclusions are presented in Section 6.

## Syntax and sequent systems for FOLID

**Syntax.** The logical framework is based on FOLID using a standard (countable) first-order language Σ. The predicate symbols are labelled either as ordinary or inductive. We assume that Σ has P1, . . . , Pn as inductive predicate symbols. The terms are defined as usual. By t, we denote a vector of terms (t1, . . . , tm) of length m, the value of m being usually deduced from the context. New terms and formulas are built from replacing (free) variables by terms via substitutions. A substitution is a mapping from variables to terms, of the form {x1 \mapsto t1; . . . ; xp \mapsto tp}, written in a more compact form as {\overline{x} \mapsto \overline{t}} , where \overline{x} is the vector of variables
An identity substitution consists only of mappings of the form \( x \mapsto x \). \( \equiv \) denotes the syntactical equality.

A term \( t \) is an instance of \( t' \) if there is a substitution \( \sigma \) such that \( t \equiv t' \sigma \). Let \( FV(\phi) \) denote the free variables of a given formula or set of formulas \( \phi \). We denote the instance of a formula \( \psi \) with \( \sigma \) by \( \psi[\sigma] \), where \( dom(\sigma) \subseteq FV(\psi) \).

Also, given a multiset of formulas \( \Psi \), \( \Psi[\sigma] \) denotes the set \( \{ \psi[\sigma] | \psi \in \Psi \} \), where \( dom(\sigma) \subseteq FV(\Psi) \).

Following [3,4], a specification is the union of the finite inductive definition sets \( \Phi_i \), defining each \( P_i \) \((i \in [1..n])\) and consisting of productions of the form

\[
Q_1(\pi_1), \ldots, Q_h(\pi_h), P_{j_1}(\bar{t}_1), \ldots, P_{j_m}(\bar{t}_m) \rightarrow P_i(\bar{t})
\]

where \( i, j_1, \ldots, j_m \in [1..n] \) and \( Q_1, \ldots, Q_h \) are ordinary predicate symbols.

The sequent-based inference system. The Gentzen’s LK system [6], presented in Fig. 1, is extended with equality and unfold rules using the definitions of inductive predicates. The proof derivations are built from sequents of the form \( \Gamma \vdash \Delta \), where \( \Gamma \) and \( \Delta \) are finite multisets of formulas, separated by commas.

The comma is an associative and commutative operator which can be classically interpreted as a conjunction in the antecedent \( \Gamma \), and as a disjunction in the succedent \( \Delta \); \( \Gamma \vdash \Delta \) can also be interpreted in FOL as the clause \( \mathcal{C}(\Gamma \vdash \Delta) \equiv (\bigvee_{F \in \Gamma} (\neg F)) \lor (\bigvee_{F \in \Delta} F) \).

By abuse of notation, \( FV(\Gamma \vdash \Delta) \) denotes the set of free variables of \( \Gamma \vdash \Delta \). The instance of the sequent \( \Gamma \vdash \Delta \) with a substitution \( \delta \), denoted by \( (\Gamma \vdash \Delta)[\delta] \), is \( \Gamma[\delta] \vdash \Delta[\delta] \). The inference system is built from inference rules. A rule is represented by a simple horizontal line that separates the premises and written above it. Side annotations may specify the name of the rule and its application conditions. Derivations are built by successive applications of inference rules and have a tree shape. When it is clear from the context, we use a double line instead of a simple line to mean that formulas may be permuted in the antecedent of the conclusion and one or several occurrences of the rules specified aside are successively applied.

---

\[
\begin{align*}
\frac{}{\Gamma \vdash \Delta} & \quad \text{(Ax)} \\
\frac{\Gamma \vdash \Delta}{\Gamma, \Delta \vdash \Delta} & \quad \text{(Wk)} \\
\frac{\Gamma \vdash F, \Delta}{\Gamma \vdash F, \Delta, \neg F} & \quad \text{(-L)} \\
\frac{\Gamma, F \vdash \Delta}{\Gamma, \neg F \vdash \Delta} & \quad \text{(-R)} \\
\frac{\Gamma, F \vdash G, \Delta}{\Gamma, F \lor G \vdash \Delta} & \quad \text{(vL)} \\
\frac{\Gamma, F \lor G \vdash \Delta}{\Gamma, F \land G \vdash \Delta} & \quad \text{(vR)} \\
\frac{\Gamma \vdash F, G, \Delta}{\Gamma \vdash F \Rightarrow G, \Delta} & \quad \text{(\Rightarrow L)} \\
\frac{\Gamma \vdash F, G, \Delta}{\Gamma, F \Rightarrow G, \Delta} & \quad \text{(-R)} \\
\frac{\Gamma \vdash F, \Delta}{\Gamma \vdash \exists F, \Delta} & \quad \text{(\exists R)} \\
\end{align*}
\]

---

\[
\text{Fig. 1. The LK rules.}
\]
The equality rules are given in Fig. 2. The (=L) rule replaces in \( \Gamma \) and \( \Delta \) occurrences of \( t \) by \( u \), as well as of \( u \) by \( t \).

\[
\frac{\Gamma \vdash t = t, \Delta}{\Gamma'[x \mapsto u; y \mapsto t], \Delta'[x \mapsto u; y \mapsto t]} \quad (= R)
\]

\[
\frac{\Gamma'[x \mapsto t; y \mapsto u], t = u \vdash \Delta'[x \mapsto t; y \mapsto u]}{\Gamma \vdash u = t, \Delta} \quad (= L)
\]

Fig. 2. The equality rules.

Assuming that (1) is the \( r \)-th production defining \( P_i \), the unfold rule applies on any sequent with a succedent formula \( P_i(t') \) for which there is a substitution \( \sigma \) such that \( P_i(t') \equiv P_i(t)[\sigma] \):

\[
\frac{\Gamma \vdash Q_1(u_1)[\sigma], \Delta, \ldots \Gamma \vdash Q_h(u_h)[\sigma], \Delta, \Gamma \vdash P_{j_1}(t_1)[\sigma], \Delta, \ldots \Gamma \vdash P_{j_m}(t_m)[\sigma], \Delta}{\Gamma \vdash P_i(t'[\delta]), \Delta} \quad (P_iR_r)
\]

The CLKID\( ^\omega \) system. It consists of the rules from Fig. 1 and Fig. 2, as well as the case-split rule representing a left-introduction operation for inductive predicate symbols:

\[
\frac{\text{case distinctions}}{\Gamma, P_i(t') \vdash \Delta} \quad \text{(Case } P_i) \]

where, for each production of the form (1), we define the case distinction

\[
\Gamma, t' = t', Q_1(u_1), \ldots, Q_h(u_h), P_{j_1}(t_1), \ldots, P_{j_m}(\bar{t}_m) \vdash \Delta \quad (2)
\]

such that, for any variable \( y \) from (1), we have \( y \notin FV(\Gamma \cup \Delta \cup P_i(t')) \) (the variable \( y \) can be renamed to a fresh one, otherwise). The formulas \( P_{j_1}(t_1), \ldots, P_{j_m}(\bar{t}_m) \) are said to be case-descendants of the active formula \( P_i(t') \).

CLKID\( ^\omega \) also includes the substitution rule:

\[
\frac{\Gamma \vdash \Delta}{\Gamma[\delta] \vdash \Delta[\delta]} \quad \text{(Subst)}
\]

The CLKID\( ^\omega \) proofs can be represented as finite graphs. Special nodes are the leaves and buds, representing terminal nodes, and some internal nodes referred to as companions.

**Definition 2.1 (Leaf, Bud).** Given a derivation tree, by leaf we understand any sequent that is the conclusion of a 0-premise inference rule, for example \((Ax)\) or \((= R)\). A bud is a sequent that is not the conclusion of any rule.

**Definition 2.2 (Companion).** Any internal node \( C \) in a derivation tree is said to be a companion for a bud \( B \) if \( C \) and \( B \) have the same sequent labelling.

**Definition 2.3 (CLKID\( ^\omega \) pre-proof tree, Induction function).** A CLKID\( ^\omega \) pre-proof tree of a sequent \( S \) is a pair \((D, R)\), where \( D \) is a finite derivation constructed with CLKID\( ^\omega \)-rules and whose root is \( S \). \( R \) is a defined induction function assigning a companion to every bud node in \( D \).
Definition 2.4 (Path in a pre-proof tree). A (finite or infinite) path in a pre-proof tree \((D, R)\) is a sequence \((S_i)_{0 \leq i < \alpha}\) of sequents from \(D\), for some \(\alpha \in \mathbb{N} \cup \{\infty\}\), such that \(S_{i+1}\) is a premise of the rule applied on \(S_i\) (resp. \(R(S_i)\)) if \(S_i\) is a non-bud (resp. bud) node.

A pre-proof is a proof if any infinite path satisfies some trace condition.

Definition 2.5 (Trace, Progress point). Let \((D, R)\) be a CLKID\(^c\) pre-proof tree and let \((\Gamma_i \vdash \Delta_i)_{i \geq 0}\) be an infinite path from its graph. A trace following \((\Gamma_i \vdash \Delta_i)_{i \geq 0}\) is a sequence \((\tau_i)_{i \geq 0}\) such that, for all \(i\), we have:

1. \(\tau_i = P_j(\bar{t_i}) \in \Gamma_i\);
2. if \(\Gamma_i \vdash \Delta_i\) is the conclusion of \((\text{Subst})\) then \(\tau_i = \tau_{i+1}[\delta]\), where \(\delta\) is the substitution associated with the rule instance;
3. if \(\Gamma_i, t = u \vdash \Delta_i\) is the conclusion of \((\neg L)\), there is a formula \(F\) and variables \(x, y\) such that \(\tau_i = F[(x \mapsto t; y \mapsto u)]\) and \(\tau_{i+1} = F[(x \mapsto u; y \mapsto t)]\);
4. if \(\Gamma_i \vdash \Delta_i\) is the conclusion of a case-split rule then either a) \(\tau_{i+1} = \tau_i\) or b) \(\tau_i\) is the active formula of the rule instance and \(\tau_{i+1}\) is a case descendant of \(\tau_i\). In the latter case, \(i\) is said to be a progress point of the trace;
5. if \(\Gamma_i \vdash \Delta_i\) is the conclusion of any other rule then \(\tau_{i+1} = \tau_i\).

An infinitely progressing trace is a trace with infinitely many progress points.

Definition 2.6 (CLKID\(^c\) proof tree). A CLKID\(^c\) proof tree is any CLKID\(^c\) pre-proof tree \((D, R)\) that satisfies the following global trace condition: for every infinite path \((\Gamma_i \vdash \Delta_i)_{i \geq 0}\) in \(D\), there is an infinitely progressing trace following some tail of the path \((\Gamma_i \vdash \Delta_i)_{i \geq k}\), for some \(k \geq 0\).

The soundness of CLKID\(^c\) is defined as in [5]. Let \(\mathcal{I}\) be a non-empty set of interpretations of sequents. If \(I \in \mathcal{I}\), we write \(I \models S\) to mean that \(S\) is true under \(I\). \(S\) is valid if \(I \models S\), for any \(I \in \mathcal{I}\). An ordinal trace function can be defined for a CLKID\(^c\) proof in order to interpret as ordinals the \(\tau\)-values from the traces following paths from the CLKID\(^c\) proof. If \(I \not\models S_i\), there is \(I' \in \mathcal{I}\) such that \(I' \not\models S_{i+1}\) and \(\alpha \leq \alpha'\), where \(\alpha\) (resp. \(\alpha'\)) is the ordinal assigned to \(\tau_i\) under \(I\) (resp. \(\tau_{i+1}\) under \(I')\). We have \(\alpha < \alpha'\) if \(i\) is a progress point. The ordinals are issued from the usual semantics of inductive predicates, which can be generated by sequences of approximants \((P^\gamma)_{\gamma \geq 0}\). The interpretation of the \(\tau\)-value for \(\vdash F(\bar{t})\) under \(I\) is the minimal \(\gamma\) such that \(\vdash P^\gamma(\bar{t})\) is true under \(I\).

Theorem 2.7 (Soundness [5]). Let us assume an ordinal trace function for a CLKID\(^c\) proof tree and \(\mathcal{I}\). If \(S\) is the root sequent, then \(S\) is valid.

The LKID system. It consists of the rules from Fig. 1 and Fig. 2 as well as the (Subst) and induction rules. The induction rules are left-introduction rules for predicate symbols. Compared to case-split rules, a formula \(P_j\) is associated to some inductive symbol \(P_j\), then is instantiated following the schema:

\[
\frac{\text{minor premises}}{\Gamma, P_j(\bar{t}) \vdash \Delta} \quad \text{(Ind } P_j)\]

5
A minor premise is built from each production defining a predicate \( P_i \) that is \( P_j \) or mutually dependent with \( P_j \). The minor premise corresponding to (1) is

\[
\Gamma, Q_1(\overline{v}_1), \ldots, Q_h(\overline{v}_h), G_{j_1}(\overline{t}_1), \ldots, G_{j_m}(\overline{t}_m) \vdash F_i(\overline{t}), \Delta 
\]  

(3)

if (1) and \( \Gamma, P_j(\overline{t}) \vdash \Delta \) do not share variables (otherwise, the variables from (1) can be renamed accordingly), and \( G_{j_1}, \ldots, G_{j_m}, F_i \) are predicates associated to \( P_{j_1}, \ldots, P_{j_m}, P_i \), respectively. \( \Gamma, F_j(\overline{t}) \vdash \Delta \) is called major premise.

**Definition 2.8 (LKID-proof).** A finite LKID derivation tree is a proof if all branches end in an axiom.

**Theorem 2.9 ([3]).** Any LKID proof can be converted to a CLKID\( ^\omega \) proof.

## 3 Structuring cyclic proofs

Any CLKID\( ^\omega \) proof can be structured by transforming it into a (Subst)-free forest, then defining a well-founded ordering on its strongly connected components.

**Converting proof trees to forests.** A proof forest can be built from any CLKID\( ^\omega \) proof tree by deleting its (Subst) steps. Before doing this, any bud \( S \) that is not the premise of a (Subst) step will become one by the following ‘stuttering’ transformation, where \( \sigma_{id} \) is the identity substitution that instantiates the free variables from \( S \):

\[
\begin{align*}
\cdots & S & \cdots \quad \text{(rule)} \\
\cdots & S' & \cdots \quad \text{(rule)}
\end{align*}
\]

Then, the subtree rooted by the premise \( S \) of any (Subst) rule that is not a bud node is detached from the proof tree to represent a new derivation tree; a copy of \( S \) is kept as a bud node and premise of the (Subst) rule, as below:

\[
\begin{align*}
\vdots & S & \vdots \\
\vdots & S & \vdots \quad \text{(bud)}
\end{align*}
\]

S \[ S[\delta] \quad \text{(Subst)}
\]

\[
\begin{align*}
\vdots & S & \vdots \quad \text{(new tree)} \\
\vdots & S & \vdots \quad \text{(bud)}
\end{align*}
\]

\[
\begin{align*}
\vdots & S & \vdots \\
\vdots & S & \vdots \quad \text{(Subst)}
\end{align*}
\]

The premise of any (Subst) rule can now be deleted and a new induction function \( \mathcal{R}' \) is defined. The conclusion \( S[\delta] \) of (Subst) becomes a bud node for which \( \mathcal{R}'(S[\delta]) = (S', \delta) \), where \( S' \) is the companion referred to by \( \mathcal{R}(S) \) in the CLKID\( ^\omega \) tree if \( S \) is a bud node; otherwise, \( S' \) is the root of the new CLKID\( ^\omega \) tree and labelled as \( S \). \( S' \) is referred to as the (forest) companion of \( S[\delta] \).

**Definition 3.1 (CLKID\( ^\omega \) pre-proof forest).** A CLKID\( ^\omega \) pre-proof forest of a sequent \( S \) is a pair (\( \mathcal{F}, \mathcal{R}' \)), where \( \mathcal{R}' \) is the new induction function and \( \mathcal{F} \) is a set of finite derivation trees resulted by deleting the (Subst) rules from the CLKID\( ^\omega \) proof tree of \( S \).

**Example 3.2 (The ‘\( P \) and \( Q \)’ example [12]).** Let us consider the productions for the inductive predicate \( N \), as well as the mutually defined predicates \( P \) and \( Q \):

\[
\begin{align*}
\rightarrow & N(0) & \rightarrow & P(0) & \rightarrow & Q(x, 0) \\
N(x) & \rightarrow N(s(x)) & P(x), Q(x, s(x)) & \rightarrow & P(s(x)) & Q(x, y), P(x) & \rightarrow & Q(x, s(y))
\end{align*}
\]

6
The sequent $N(x) \vdash P(x)$ is the root of the annotated CLKID$^\omega$ pre-proof, where $\mathcal{R}((\ast 1)) = \mathcal{R}((\ast 2)) = (\ast)$ and $\mathcal{R}((\parallel 1)) = (\parallel)$.

\[
\begin{array}{c}
\frac{N(x) \vdash P(x) \quad (\ast 1)}{N(x') \vdash P(x')} \quad (\text{Subst}) \\
\frac{N(s(x')) \vdash P(s(x')) \quad (\ast 2)}{N(x), x = s(x'), N(x') \vdash P(x)} \quad (\text{Case } N), (\text{Wk}) \\
\frac{x = 0 \vdash P(x) \quad (\ast)}{N(x), N(x) \vdash P(x)} \quad (\text{ContrL}) \\
\end{array}
\]

(\text{PR}_2), (\text{Wk})

For lack of horizontal space, the rightmost branch of the pre-proof tree, annotated by (\ast 2), is developed separately below.

\[
\begin{array}{c}
\frac{N(x) \vdash P(x)}{N(u) \vdash P(u)} \quad (\text{Subst}) \\
\frac{N(u), v \vdash Q(u, v)}{N(u), N(v') \vdash Q(x, s(x'))} \quad (\text{Subst}) \\
\frac{N(x') \vdash Q(x', s(x')) \quad (\ast 2)}{N(s(x')), N(x') \vdash Q(s(x'), x') \quad (\text{Subst})} \\
\frac{x = 0 \vdash P(x) \quad (\ast)}{N(x), N(x) \vdash P(x)} \quad (\text{ContrL}) \\
\end{array}
\]

\[
\begin{array}{c}
\frac{N(x) \vdash P(x)}{N(u) \vdash P(u)} \quad (\text{Subst}) \\
\frac{N(u), v \vdash Q(u, v)}{N(u), N(v') \vdash Q(x, s(x'))} \quad (\text{Subst}) \\
\frac{N(x') \vdash Q(x', s(x')) \quad (\ast 2)}{N(s(x')), N(x') \vdash Q(s(x'), x') \quad (\text{Subst})} \\
\frac{x = 0 \vdash P(x) \quad (\ast)}{N(x), N(x) \vdash P(x)} \quad (\text{ContrL}) \\
\end{array}
\]

(\text{PR}_2), (\text{Wk})

The premise of the (Subst) rule applied on (\ast 2) is not a bud and a new tree is generated. Finally, the pre-proof forest $F$ is made of two trees:

\[
\begin{array}{c}
\frac{N(x) \vdash P(x) \quad (\ast 1)}{N(x') \vdash P(x')} \quad (\text{Subst}) \\
\frac{N(s(x')) \vdash P(s(x')) \quad (\ast 2)}{N(x), x = s(x'), N(x') \vdash P(x)} \quad (\text{Case } N), (\text{Wk}) \\
\end{array}
\]

(\text{PR}_2), (\text{Wk})

For each bud, the pair value computed by $\mathcal{R}'$ is displayed above the bud. △

**Definition 3.3 (Path in a pre-proof forest).** A finite (or infinite) path in the pre-proof forest $(F, \mathcal{R}')$ is a sequence $(S_i)_{0 \leq i < \alpha}$ of sequents from $F$, for some $\alpha \in \mathbb{N} \cup \{\infty\}$, such that $S_{i+1}$ is a premise of the inference rule applied on $S_i$ (resp. $S$ satisfying $\mathcal{R}'(S_i) = (S, \delta)$) in a non-bud (resp. bud) node.

A finite path $(S_i)_{0 \leq i \leq n}$ is bud-free (resp. companion-free) if no $S_j$ with $j \in [0..n-1]$ is a bud (resp. companion).

The traces in pre-proof forests are defined similarly as for pre-proof trees. Let $(F, \mathcal{R}')$ be a CLKID$^\omega$ pre-proof forest and $(T_i \vdash \Delta_i)_{i \geq 0}$ a path in it. A (forest) trace following $(T_i \vdash \Delta_i)_{i \geq 0}$ is a sequence $(\tau_i)_{i \geq 0}$ such that, for all $i$, the conditions from Definition 2.5 are satisfied. In addition, when $T_i \vdash \Delta_i$ is a bud node for which $\mathcal{R}'(T_i \vdash \Delta_i) = (S, \delta)$, we have $\tau_i = \tau_{i+1}[\delta]$. 

7
Lemma 3.4. \( G \) is a path (resp. trace, progress point) in a pre-proof tree iff it is also a path (resp. trace, progress point) in the corresponding pre-proof forest.

Proof. By the construction of pre-proof forests.

Definition 3.5 (CLKID\( ^\omega \) proof forest). A CLKID\( ^\omega \) proof forest is any CLKID\( ^\omega \) pre-proof forest \((F, R')\) that satisfies the following global trace condition: for every infinite path \((\Gamma_i \vdash \Delta_i)_{i \geq 0}\) in \(F\), there is an infinitely progressing trace following some tail of the path \((\Gamma_i \vdash \Delta_i)_{i \geq k}\), for some \(k \geq 0\).

Theorem 3.6. Let us assume a CLKID\( ^\omega \) proof tree based on an ordinal trace function and \(I\). The corresponding CLKID\( ^\omega \) pre-proof forest is a proof.

Proof. By Lemma 3.4 and the fact that the CLKID\( ^\omega \) proof tree satisfies the global trace condition.

Building the partition with ordered parts. Given a pre-proof forest \(F\) built from a proof tree \(T\), we say that a node \(A\) is connected to a node \(B\) if there is a path from \(A\) to \(B\). The companions found in each strongly connected component of the graph represented by \(F\) and identifying maximal cycles in the graph, will build a part for the partition \(P\). \(P\) will also integrate the singleton containing the root sequent of \(T\) if it is not a companion, as well as the singletons built from the companions that are not included in any strongly connected component.

Example 3.7. The partition generated for the pre-proof forest built by Example 3.2 consists of only one part made of the two companions \(N(x) \vdash P(x)\) and \(N(u), N(v) \vdash Q(u, v)\).

Definition 3.8 (dependency relation). Let \(\pi_1\) and \(\pi_2\) be two parts from a partition \(P\). We say that \(\pi_2\) depends on \(\pi_1\) and write \(\pi_1 \prec \pi_2\) if, for any \(S_1 \in \pi_1\) and \(S_2 \in \pi_2\), there is a path from \(S_2\) to \(S_1\) but no path from \(S_1\) to \(S_2\).

Lemma 3.9. \(\prec\) is a terminating ordering relation.

Proof. We show that \(\prec\) is irreflexive, asymmetric and transitive.

- irreflexivity. For any part \(\pi \in P\) and any two distinct sequents \(S_1, S_2 \in \pi\), there is a path from \(S_1\) to \(S_2\) but also a path from \(S_2\) to \(S_1\). So, \(\pi \not\prec \pi\).
- asymmetry. If \(\pi_1 \prec \pi_2\) then \(\pi_2 \not\prec \pi_1\), for any distinct \(\pi_1, \pi_2 \in P\). Otherwise, the elements of \(\pi_1\) and \(\pi_2\) are in the same strongly connected component.
- transitivity. Assume that \(\pi_1, \pi_2, \pi_3 \in P\) such that \(\pi_1 \prec \pi_2\) and \(\pi_2 \prec \pi_3\). Then there exist \(S_1 \in \pi_1\), \(S_2 \in \pi_2\) and \(S_3 \in \pi_3\) such that there are two paths leading \(S_1\) to \(S_2\), and \(S_2\) to \(S_3\), respectively. Their concatenation is a path leading \(S_1\) to \(S_3\). On the other hand, there is no sequence followed by a trace leading \(S_3\) to \(S_1\). Otherwise, \(S_1, S_2\) and \(S_3\) would be in the same strongly connected component, hence in the same part. We conclude that \(\pi_1 \prec \pi_3\).

\(\prec\) is also terminating (well-founded) since \(P\) has a finite number of parts.
4 The LKID\textasciicircum system

We define LKID\textasciicircum as the extension of LKID with the (PInd)-rule:

\[
\begin{array}{c}
\text{companions} \quad \text{axioms} \\
S \in \pi \quad (\text{PInd } \pi)
\end{array}
\]

The rule requires that \(S\) be a sequent from the part \(\pi\) included in a partition \(P\) computed for some CLKID\textasciicircum forest proof. For each terminal node or companion \(N\) for which there exists a bud- and companion-free path leading a \(\pi\)-sequent to \(N\), we will consider as premise for (PInd):

- \(N\) if it is an axiom, or
- the axiom \(C(N) \vdash C(N')\) if \(N\) is a bud and \(R'(N) = (N', \delta)\), \(N' \in \pi\), or
- \(N\) if it is a companion \(\notin \pi\), or
- \(N'\) if \(N\) is a bud, \(R'(N) = (N', \delta)\) and \(N' \notin \pi\).

Any LKID\textasciicircum derivation is a proof if all branches end in an axiom.

Example 4.1. The LKID\textasciicircum proof of \(\vdash P(x)\) starts with the application of (PInd), issued from the structural analysis of the proof forest \(F\) from Example 3.2. According to Example 3.7, there is only one partition for \(F\). The premises of (PInd) are built only from the axioms \(\vdash P(0)\), \(N(u) \vdash Q(u, 0)\), and \(C \vdash C\), where \(C\) is the clause interpreting each of the sequents \(N(x') \vdash P(x')\), \(N(u), N(s(x')) \vdash Q(x', s(x'))\), \(N(u) \vdash P(u)\), and \(N(u), N(u') \vdash Q(u, u')\).

Theorem 4.2. LKID\textasciicircum and CLKID\textasciicircum are equivalent.

Proof. The ‘\(\Rightarrow\)’ part. We follow similar arguments as in [4]. The transformation of the (Ind) rule is described by Lemma 7.3.1. The (PInd \(\pi\)) rule is translated into the strongly connected component corresponding to the part \(\pi\) computed for a previous CLKID\textasciicircum forest. As in the proof of Theorem 7.3.2, the set of strongly connected components of the resulted CLKID\textasciicircum forest \(F\) is the disjoint union of the strongly connected components introduced by the (Ind) and (PInd) rules. Hence, Proposition 7.2.3 can be applied for \(F\) and conclude that it is a proof.

The ‘\(\Leftarrow\)’ part. Given a CLKID\textasciicircum proof \(D\), it is firstly transformed into a proof forest \(F\), then into a successive applications of (PInd) rules using parts from \(F\) and starting with the root sequent of \(D\). The resulted LKID\textasciicircum derivation, denoted by \(E\), is finite because i) for any application of a (PInd \(\pi\)) rule, the part \(\pi'\) of any companion from its premises is smaller (w.r.t. \(<_P\)) than \(\pi\), and ii) \(<_P\) is a terminating ordering, by Lemma 3.9.

5 The LKID\textasciicircum system

Given the partition \(P\) for a CLKID\textasciicircum proof, the LKID\textasciicircum system extends LKID to deal with a new predicate symbol \(P\) defined for each part \(\pi \in P\). The set \(\Phi_{P_\pi}\) has a unique production of the form \(F(\overline{x}) \rightarrow P_\pi(\overline{x})\), where \(F(\overline{x})\) is the
conjunction formula $\bigwedge_{S \in \pi} C(S)$ and $\vec{x}$ is its vector of free variables. The other productions of $\Phi_{P_\pi}$ are of the form $P_x(\vec{t}_i) \rightarrow P_x(\vec{t}_i)$ or $\rightarrow P_x(\vec{t}_k)$. Productions using non-atomic premises have already been proposed by Martin-Löf [7] for iterated inductive definitions.

The conclusion of the (Ind) rule extended for $P_\pi$ is the sequent $P_\pi(\vec{x}) \vdash F(\vec{x})$ and the two rightmost premises are axioms (they are further omitted), the first derived from the production $F(\vec{x}) \rightarrow P_\pi(\vec{x})$ and the second as the major premise:

$$
\frac{F(\vec{x}_j) \vdash F(\vec{t}_i) \ldots \vdash F(\vec{t}_k) \ldots \vdash F(\vec{x}) \vdash F(\vec{x}) \vdash F(\vec{x})}{P_\pi(\vec{x}) \vdash F(\vec{x})} \quad \text{(Ind $P_\pi$)}
$$

The LKID$_c$ system also integrates an axiom rule for $P_\pi$:

$$
\vdash P_\pi(\vec{x}) \quad (Ax P_\pi)
$$

The (NInd $P_\pi$) rule encodes the Noetherian induction. Defined below on the left of $\equiv$, it is the abbreviation of the LKID$_c$ derivation on the right of $\equiv$:

$$
\frac{F(\vec{x}_j) \vdash F(\vec{t}_i) \ldots \vdash F(\vec{t}_k) \ldots \vdash F(\vec{x})}{P_\pi(\vec{x})} \equiv
\frac{P_\pi(\vec{x}) \vdash F(\vec{x})}{(NInd P_\pi)}
$$

$$
\frac{P_\pi(\vec{x}) \vdash F(\vec{x})}{(Ax P_\pi)} \quad \frac{P_\pi(\vec{x}) \vdash F(\vec{x})}{(Cut)}
$$

**Definition 5.1 (LKID$_c$-proof).** A finite LKID$_c$ derivation tree is a proof if all branches end in an axiom.

**Generating the productions for $P_\pi$.** Each production for $P_\pi$ corresponds to an induction case of the induction schema built for $\vdash F(\vec{x})$, which is a composition of individual induction schemas built for the sequents $\vdash C(S), S \in \pi$.

**Building the individual induction schemas.** Each node from the pre-proof forest will be decorated by a substitution. Any premise from a case-split rule, of the form (2), will be decorated by $\{x \mapsto t|(x \mapsto t) \in \mu$ and $x$ is a variable from $\vec{t}\}$, where $\mu$ is the mgu of $\vec{t}$ and $\vec{t}$ such that $\vec{t} \mu = \vec{t}_i$. In the following, we assume that $\vec{t}$ and $\vec{t}$ are constructor terms built only from variables and free constructor symbols, i.e. there is no equality relation between two distinct constructor symbols. In this case, the mgu relation can be computed using syntactic unification algorithms [2]. The other nodes will be decorated with identity substitutions that instantiate their free variables.

Given the sequents $S$ from $\pi$ and $B$ from a bud-free path starting with $S$, called cumulative path, we can build a unique cumulative substitution.

**Definition 5.2 (Cumulative substitution).** Given a cumulative path $(\Gamma_i \vdash \Delta_i)_{i \in [0..n]}$, its cumulative substitution $\theta$ is

$$
\{\sigma_0 \ldots \sigma_{n-1} \mid \sigma_i \text{ is the substitution decorating } (\Gamma_i \vdash \Delta_i), \forall i \in [0..n-1]\}
$$

**Example 5.3.** 0 and $s$ are the free constructor symbols for naturals. The substitutions associated to the left and right premises of the (Case $N$) rule are $\{x \mapsto 0\}$ and $\{x \mapsto s(x')\}$, and for (Case $Q$) are $\{v \mapsto 0\}$ and $\{v \mapsto s(v')\}$, respectively.
The cumulative substitutions computed for the cumulative paths leading to the root sequents to the terminal nodes of the pre-proof forest built in Example 3.2 are: i) \( \{ x \mapsto 0 \} \) for \( \vdash P(0) \), ii) \( \{ x \mapsto s(x') \} \) for \( N(x') \vdash P(x') \) and \( N(x'), N(s(x')) \vdash Q(x', s(x')) \), iii) \( \{ v \mapsto 0 \} \) for \( N(u) \vdash P(u, 0) \), and iv) \( \{ v \mapsto s(v') \} \) for \( N(u) \vdash P(u) \) and \( N(u), N(v') \vdash Q(u, v') \).

**Lemma 5.4.** If \( \theta_B \) is the cumulative substitution of the cumulative path \((S_i)_{0 \leq i \leq n}\) leading to \( S \) to \( B \) (i.e., \( S_0 \equiv S \) and \( S_n \equiv B \)) i) the rules applied at each step \( i \in [0..n-1] \) can be reapplied to build a new path \((S'_i)_{0 \leq i \leq n}\) such that \( S_0' \equiv S_0[\theta_B], S_n' \equiv B \), ii) for any \( i \in [1..n-1] \), there is a substitution \( \theta_i \) such that \( S_i'[\theta_i] \equiv S_i \), and iii) the (case-split) rules do not instantiate free variables.

**Proof.** We will perform by induction on the length of the path leading \( S_0 \) to \( B \). If \( n = 0 \), then \( B \equiv S_0 \) and \( \theta_B \) is the identity substitution.

If \( n > 0 \), let us assume that the path \( p \) of length \( n \) and leading \( S_0 \) to \( B \) has the form \( S_0, \ldots, S_{n-1}, B \). Also, let \( \theta_{S_{n-1}} \) be the cumulative substitution for \( S_0, \ldots, S_{n-1} \). By induction hypothesis, we assume that any path of length \( n-1 \) satisfies the property, in particular \( S_0, \ldots, S_{n-1} \). So, the steps from \( S_0, \ldots, S_{n-1} \) can be reapplied to build the path \( S_0', \ldots, S_{n-1}' \) such that \( S_0' \equiv S_0[\theta_{S_{n-1}}], S_n' \equiv S_{n-1} \) and for \( i \in [1..n-2] \), there is a substitution \( \theta_i \) such that \( S_i'[\theta_i] \equiv S_i \).

Let \( \sigma \) be the substitution decorating \( S_n \) and \( \theta_B \) the cumulative substitution for \( p. \sigma \) can be either an identity substitution, or an mgu substitution instantiating free variables from \( S_{n-1} \). For the first case, \( \theta_B \) equals \( \theta_{S_{n-1}} \) and the re-execution of the rule applied at the step \( n-1 \) of \( p \) on \( S_{n-1}' \) generates \( B \). In the second case, \( \theta_B \) is the substitution composition \( \theta_{S_{n-1}} \sigma \). The path \((S'_i)_{0 \leq i \leq n}\) is defined as \( S'_i \equiv S'_i[\sigma] \), for any \( i \in [0..n-1] \), and \( S'_n \equiv B \). No instantiation of free variables is performed when the case-split rule is applied on \( S_{n-1}' \).

**Example 5.5.** Let us assume the cumulative path pre-proof forest given in Example 3.2, for which the sequents are decorated with substitutions (excepting the last sequent): \( (N(x) \vdash P(x), \{ x \mapsto x \}), (N(x), N(x) \vdash P(x), \{ x \mapsto s(x') \}), (N(x), x \equiv s(x'), N(x) \vdash P(x), \{ x \mapsto x; x' \mapsto x' \}), (N(s(x'))), (N(x') \vdash P(s(x'))), \{ x' \mapsto x' \}, (N(x')) \vdash P(x')). \)

The cumulative substitution is \( \{ x \mapsto s(x') \} \) and the new path is:

\( (N(s(x')) \vdash P(s(x'))), (N(s(x'))), (N(s(x'))), (N(x')) \vdash P(s(x'))), (N(x')) \vdash P(s(x'))), (N(x') \vdash P(x')). \)

An induction schema for a sequent \( S \) is a collection of induction cases that attach a (potentially empty) set of sequents, called induction hypotheses, to an instance of \( S \), called induction conclusion.

**Definition 5.6 (individual induction schema).** Let \( S \in \pi (\pi \in \mathcal{P}) \). For each companion-free cumulative path leading to \( S \) to \( (a terminal node or companion) N \), we build an induction case of the individual induction schema for \( \vdash C(S) \) having:

- \( \vdash C(S)[\theta_N] \) as induction conclusion built with the cumulative substitution \( \theta_N \),
- \( \vdash C(S_N)[\delta] \) as induction hypothesis if \( N \) is a bud node for which \( \mathcal{R}'(N) = (S_N, \delta) \) and \( S_N \in \pi \), or \( \vdash C(N) \) if \( N \) is a companion from \( \pi \).
Example 5.7. Considering the part from Example 3.7, let us denote by \( C_1(x) \) (resp. \( C_2(u,v) \)) the clause \( C(N(x) \vdash P(x)) \) (resp. \( C(N(u), N(v) \vdash Q(u,v)) \)). By using the cumulative substitutions from Example 5.3, the induction cases of the individual induction schema for

\[
\vdash C_1(x) \text{ are: i) } \vdash C_1(0), \text{ and ii) } \vdash C_1(s(x')) \text{ with the induction hypotheses } \\
\vdash C_1(x') \text{ and } \vdash C_2(x', s(x')).
\]

\[
\vdash C_2(u,v) \text{ are: i) } \vdash C_2(u,0), \text{ and ii) } \vdash C_2(u, s(v')) \text{ with the induction hypotheses } \\
\vdash C_1(u) \text{ and } \vdash C_2(u, v').
\]

Generating productions for new predicate symbols. Let \( \pi_{i_1...i_k} \) be a part built on \( k(>0) \) sequents \( S_{i_1}, \ldots, S_{i_k} \), where \( i_1, \ldots, i_k \in [1,k] \) is a permutation of the values from \([1,k]\). Let also \( C_{i_p} (\pi_{i_p}) \) be \( C(S_{i_p}) \) (\( p \in [1,k] \)) with \( \pi_{i_p} \) the vector of free variables from \( C(S_{i_p}) \) and \( D_{i_p}^1 \times \ldots \times D_{i_p}^j \) the domain of \( C_{i_p} \). The new inductive predicate symbol \( P_{\pi_{i_1...i_k}} \) with the domain \( D_{i_1}^1 \times \ldots \times D_{i_k}^1 \times \ldots \times D_{i_k}^j \) is defined by the smallest set of productions of the form

\[
\text{premises} \rightarrow P_{\pi_{i_1...i_k}} (t_{i_1}^1, \ldots, t_{i_1}^{i_1}, \ldots, t_{i_k}^1, \ldots, t_{i_k}^{i_k}) \tag{4}
\]

Each of the sequents \( \vdash C_{i_p} (t_{i_1}^1, \ldots, t_{i_1}^{i_1}, \ldots, t_{i_k}^1, \ldots, t_{i_k}^{i_k}) \) (\( p \in [1,k] \)) defined on every (sub)vector given as argument to the conclusion of (4) is the conclusion of an individual induction case defined for \( \vdash C_{i_p} (\pi_{i_p}) \). For each of its attached induction hypotheses, there is a premise of (4) defined as follows. If the induction hypothesis is the sequent \( \vdash C_{i_r} (\overline{t}_{i_r}) \) (\( r \in [1,k] \)), the premise is the induction conclusion of (4) for which the \( r \)th (sub)vector is replaced by \( \overline{t}_{i_r} \). The premises that replace distinct (sub)vectors are factorized into a single premise.

Example 5.8. \( P_{\pi_{12}} \) is defined by the productions issued from the individual induction schemas for \( \vdash C_1(x) \) and \( \vdash C_2(u,v) \), computed at Example 5.7: \( \vdash P_{\pi_{12}} (0, u, 0), P_{\pi_{12}} (x', x', s(x')) \rightarrow P_{\pi_{12}} (s(x'), u, 0), P_{\pi_{12}} (u, u, v') \rightarrow P_{\pi_{12}} (0, u, s(v')), \text{ and } P_{\pi_{12}} (x', x', s(x')), P_{\pi_{12}} (u, u, v') \rightarrow P_{\pi_{12}} (s(x'), u, s(v')). \triangle
\]

Applying the (NInd) rule on a part sequent. The proof of \( \Gamma \vdash \Delta \in \pi_{i_1...i_k} \) starts by applying a (Cut) using the conjunction formula of \( \pi_{i_1...i_k} \):

\[
\frac{\Gamma, \mathcal{C} (\Gamma \vdash \Delta) \vdash \Delta \quad \text{(the induction cases)} \quad (\text{NInd } P_{\pi_{i_1...i_k}})}{\Gamma \vdash \Delta}
\]

Each induction case is further transformed into the individual induction cases that built it, by firstly deleting the conjunction symbols from the antecedent using successive applications of \( (\land L) \) rules, then the conjunction symbols from the succedent using the \( (\land R) \) rule. The antecedent formulas from each new sequent, that are not induction hypotheses attached to the induction conclusion from the succedent, are deleted by the (Wk) rule. The induction step is summarized as:
Proving the individual induction cases. The derivation of the individual case $C_1, \ldots, C_p \vdash \mathcal{C}(\Gamma \vdash \Delta)[\theta]$ for $\Gamma \vdash \Delta$ using the cumulative substitution $\theta$ is

\[
\frac{C_1, \ldots, C_p, \Gamma_1 \vdash \Delta}{C_1, \ldots, C_p, \mathcal{C}(\Gamma \vdash \Delta)[\theta]}_{(\forall L), (\neg R)}
\]
The derivation of \( C_1, \ldots, C_p, \Gamma[\theta] \vdash \Delta[\theta] \) starts by executing the rules from the companion-free cumulative paths of the CLKID\(^{\omega} \) pre-forest leading \( \Gamma \vdash \Delta \) to the terminal nodes and companions for which the cumulative substitution is \( \theta \), as shown in the proof of Lemma 5.4. We perform a case analysis on them.

The LKID\(_c\) derivation for a leaf is (Ax). For any companion \( \Gamma_j \vdash \Delta_j \) or bud whose companion \( \Gamma_j \vdash \Delta_j \) is not in \( \pi_1, \ldots, \pi_k \), the derivation is developed as for \( \Gamma \vdash \Delta \). The sequent corresponding to any other node has in the antecedent a clause \( C \) that interprets the node; it is proved by decomposing \( C \), as previously.

**Example 5.10.** The derivations of the individual induction cases \( \vdash C_1(0) \) and \( \vdash C_2(u, 0) \) from Example 5.9, after expansion to their clausal definition, are:

\[
\begin{align*}
\vdash P(0) & \quad (Ax) \\
\vdash \neg N(0) \lor P(0) & \quad (\lor R), (Wk) \\
\vdash Q(u, 0) & \quad (Ax) \\
\vdash \neg N(u) \lor \neg N(0) \lor Q(u, 0) & \quad (\lor R), (Wk)
\end{align*}
\]

The derivation of the case \( \vdash C_1(u), C_2(u, v') \vdash C_2(u, s(v')) \) is:

\[
\begin{align*}
P(u) & \vdash \neg N(u), P(u) \quad (Ax) \\
\vdash \neg N(u) \lor P(u) & \quad (\neg L) \quad (\lor R) \\
\vdash \neg N(u), P(u) & \quad (QR), (Wk) \\
\vdash \neg N(u) \lor \neg N(v') \lor Q(u, v') & \quad (\lor R) \\
\vdash \neg N(u), \neg N(v'), Q(u, v') & \quad (\lor R) \\
\vdash \neg N(u) \lor \neg N(v') \lor Q(u, s(v')) & \quad (\lor R) \quad (Ax)
\end{align*}
\]

where the derivation of the leftmost sequent, denoted by (**), is:

\[
\begin{align*}
\vdash \neg N(u) \lor \neg N(v') \lor Q(u, v') & \quad (\lor R), (Ax)
\end{align*}
\]

The derivation of \( \vdash C_1(x'), C_2(x', s(x')) \), \( N(x') \vdash C_1(s(x')) \) is done similarly. △

**Lemma 5.11.** (NInd) is locally sound and implements Noetherian induction.

**Theorem 5.12.** LKID\(_c\) and CLKID\(^{\omega} \) are equivalent.

**Proof.** The ‘ \( \Rightarrow \)’ part. (Ind) using new predicate symbols is an instance of LKID\(_c\) (Ind), hence translatable into CLKID\(^{\omega} \). The application of (Ax \( P_\pi \)) on \( \vdash P_\pi(\pi) \) is translated to the application of (\( P_\pi R \)) using the production \( \Lambda_{S \in \pi} C(S) \rightarrow P_\pi(\pi) \) which yields the sequent \( \vdash \Lambda_{S \in \pi} C(S) \). By decomposing it using conveniently the (\( \Lambda R \)), (\( \lor R \)) and (\( \land R \)) rules, we get the sequents \( \vdash S, S \in \pi \). Each of them is proved by the CLKID\(^{\omega} \) (forest) proof of \( \pi \).

The ‘ \( \Leftarrow \)’ part. By generating the partition \( \mathcal{P} \) from the CLKID\(^{\omega} \) proof \( \mathcal{T} \), then applying recursively the procedure for developing the derivation of a part sequent starting with the root of \( \mathcal{T} \). The process terminates as \( <_P \) is terminating. □

**Corollary 5.13.** Noetherian induction can represent structural and cyclic induction reasoning performed by LK extended with new inductive predicates.

**Proof.** By Theorems 4.2 and 5.12 since our procedure converts any CLKID\(^{\omega} \) proof to an LKID\(_c\) proof using only (NInd)-based induction reasoning. □
6 Conclusions and perspectives

We have shown that structural and cyclic induction reasoning in FOLID are convertible and are subsumed by Noetherian induction. Compared to LKID, LKID can generate proofs that combine the advantages of structural and cyclic reasoning by the dynamic definition of new induction schemas. Our procedure transforms effectively cyclic to structural proofs and does not require unfolding operations as in [8] or as suggested in [3,4].

These results open the perspective for validating CLKIDω-like proofs by (higher-order) certification environments integrating the Noetherian induction principle, like Coq [11], by using similar certification methodologies as for implicit induction [10]. Also, it would be interesting to extend CLKIDω for integrating reductive-free cycles [9].

References

A The proof of Lemma 5.11

Let $\pi$ be a part of the partition $P$ from a proof forest $F$ built from a CLKID$_\omega$ proof tree $T$, based on the ordinal trace function $f$ and the non-empty set of interpretations $I$.

By absurd, assume that $(\text{NInd } P_{\pi})$ is applied in some CLKID$_\omega$ derivation $D$ with valid premises but false conclusion. The conclusion is $\vdash F(\pi)(\equiv \bigwedge_{S \in \pi} C(S))$, hence there is a sequent $S \in \pi$ that is false. By Definition 3.5, the definition of ordinal trace functions and Lemma 3.4, there is an infinite path $S_{i \geq 0}$ of false sequents in $F$ starting with $S$, and an infinitely progressing trace following some tail of $S_{i \geq k}$, for some $k \geq 0$. Since $F$ has a finite number of nodes, there is a companion $S'$ that is infinitely often visited in the path. Since any companion from $F$ is in a part of $P$, we consider $\pi' \in P$ such that $S' \in \pi'$.

The rule $(\text{NInd } P_{\pi'})$ should be also applied in $D$, otherwise $S'$ cannot occur infinitely in $S_{i \geq k}$. Its conclusion $\vdash F'(\pi')(\equiv \bigwedge_{S \in \pi'} C(S))$ is false. Let $S_{k_1}$ be the first occurrence of $S'$ in $S_{i \geq k}$ and $S_{k_2}$, with $k_1 < k_2$, the occurrence of the next visited companion $S'' \in \pi'$ in $S_{i \geq k}$. Let also assume that the $\tau$-value of $S_{k_1}$ and $S_{k_2}$ in the trace is $\alpha_{k_1}$ and $\alpha_{k_2}$, respectively. There should be a premise of $(\text{NInd } P_{\pi'})$, built from a companion-free cumulative path $\pi \in F$ leading a false cumulative instance of $S'$ to a false instance of $S''$ or some bud node whose companion is $S''$, by Lemma 5.4. We denote by $F'(\pi_{k_1}) \vdash F'(\pi_{k_2})$ the instance of the premise leading $S_{k_1}$ to $S_{k_2}$ and notice that both $F'(\pi_{k_1})$ and $F'(\pi_{k_2})$ are false. We associate to the term vectors $\pi_{k_1}$ and $\pi_{k_2}$ the weights $\alpha_{k_1}$ and $\alpha_{k_2}$, respectively. We proceed similarly for $S_{k_2}$ as for $S_{k_1}$, as well as for any future occurrence of companions from $\pi'$ in $S_{i \geq k}$.

Let us define $E' = \{ \pi_p \mid S_p$ is an occurrence of $S'$ in $S_{i \geq k}$, and $F'(\pi_p)$ has $C(S_p)$ as one of its conjuncts $\}$. We have that

\[(\forall \pi_p \in E', \neg F'(\pi_p) \Rightarrow (\exists \pi_j \in E', \pi_j < \pi_p \land \neg F'(\pi_j))) \quad (5)\]

i) by taking, for an arbitrary $\pi_p$, the vector $\pi_j$ such that $\pi_j$ is the next occurrence of $S'$ in $S_{i \geq k}$ that follows $\pi_p$ for which there is a progress point between $\pi_j$ and $S_p$, ii) by successively considering the companions from $\pi'$ in $S_{i \leq j < p}$, and iii) by using the definition of ordinal trace functions and the transitivity property of $\prec$. The Noetherian induction principle

\[\forall \phi, (\forall m \in E, (\forall k \in E, k < m \Rightarrow \phi(k)) \Rightarrow \phi(m)) \Rightarrow \forall p \in E, \phi(p)\]

can be applied on the contrapositive version of (5) when instantiating $E$ by $E'$ and $\phi$ by $F'$, to conclude that $\forall p \in E', F'(p)$. Contradiction since $F'(p)$ is false, for any $p \in E'$.
