Active and passive earth pressure coefficients by a kinematical approach

A.-H. Soubra and B. Macuh

A simple method is proposed for calculating the active and passive earth pressure coefficients in the general case of an inclined wall and a sloping backfill. The approach used is based on rotational log-spiral failure mechanisms in the framework of the upper-bound theorem of limit analysis. It is shown that the energy balance equation of a rotational log-spiral mechanism is equivalent to the moment equilibrium equation about the centre of the log-spiral. Numerical optimisation of the active and passive earth pressure coefficients is performed automatically by a spreadsheet optimisation tool. The implementation of the proposed method is illustrated using an example. The predictions by the present method are compared with those given by other authors.

NOTATION
\[
\begin{align*}
\delta & \quad \text{friction angle at the soil–structure interface} \\

\]

1. INTRODUCTION

The problem of active and passive earth pressures acting against rigid retaining structures has been extensively studied in the literature since Coulomb.\(^1\) Most of the existing methods are based on either the limit equilibrium method, the slip line method or the limit analysis method.

Recently, a variational analysis has been applied to the passive earth pressure problem by Soubra et al.\(^2\). Their approach is based on a limit equilibrium method, and the solution provides a log-spiral failure surface. For their failure wedge, the moment equilibrium equation can be used for the calculation of the passive earth pressures without specifying the normal stress distribution along the log-spiral slip surface. It should be emphasised that their method, employed in this paper, can be categorised also as an upper-bound in the framework of limit analysis where a rotational rigid body movement is considered.

This variational limit equilibrium method may be easily extended to the active earth pressure problem, and the same conclusions remain valid in this case:

(a) A log-spiral failure surface may be obtained from a variational maximisation procedure.

(b) The moment equilibrium equation, which is equivalent to the energy balance equation in the framework of the upper-bound method of limit analysis, may be used for computation of the active earth pressures.

The aim of this paper is to show that the upper-bound method in limit analysis for a rotational log-spiral failure mechanism gives rapid and good predictions for both active and passive earth pressures. It is also demonstrated that the present method can be easily implemented on a PC by defining spreadsheet...
functions and by using a powerful spreadsheet optimisation tool. The analysis is made in the general case of an inclined wall and a sloping backfill, and considers a frictional and cohesive \((c, \phi)\) soil. A uniform surcharge is assumed to act on the ground surface. Active and passive earth pressure coefficients due to soil weight, cohesion and surcharge loading are presented for various governing parameters and compared with those given by other authors.

2. FAILURE MECHANISMS AND GOVERNING EQUATIONS
The variational analysis details and the equivalence between the variational limit equilibrium method and the upper-bound method in limit analysis for a rotational log-spiral failure mechanism are given elsewhere. However, for clarity, only the upper-bound technique (that is, the kinematical approach) of limit analysis is briefly described here.

Two rotational log-spiral failure mechanisms are considered in the present analysis, one for the active state M1 (Fig. 1(a)) and the other for the passive state M2 (Fig. 1(b)). For both M1 and M2 mechanisms, the region ABC rotates as a rigid body about the as yet undefined centre of rotation \(O\) relative to the material below the logarithmic failure surface BC. Thus the surface BC is a surface of velocity discontinuity. These failure mechanisms can be specified completely by two variables \(\theta_0\) and \(\theta_1\). It should be emphasised that the earth pressure coefficient due to soil weight, \(K_w\), is calculated with the assumption of a cohesionless soil with no surcharge loading. The computation of the coefficients \(K_q\) and \(K_c\) due to surcharge loading and cohesion is based on the assumption of a weightless soil with \(c = 0\) for \(K_q\) and \(q = 0\) for \(K_c\). The formulation for the coefficients of earth pressure due to soil weight, surcharge and cohesion follows.

2.1. Rate of work of external forces
As shown in Fig. 1, the external forces acting on the soil mass in motion consist of the self-weight of the soil, \(W\), the active or passive earth force \((P_a\) or \(P_p\)), the adhesive force, \(P_{ad} = \frac{c}{\tan \phi}\), and the surcharge, \(qL\), acting on the ground surface. The rate of work for the different external forces can be calculated as follows.

2.1.1. Rate of work of the soil weight. A direct integration of the rate of work of the soil weight in the region ABC is very complicated. An easier alternative is first to find the rate of work \(W_{OBC}\), \(W_{OAB}\) and \(W_{OAC}\) due to soil weight in the regions OBC, OAB and OAC respectively. The rate of work for the

Fig. 1. Log-spiral failure mechanisms: (a) M1 for active; (b) M2 for passive earth pressure analyses
region ABC is then found by simple algebraic summation, \( W_{ABC} - W_{OAB} - W_{OAC} \). The steps of computation of the rate of work due to self-weight of the soil are essentially the same as those of an inclined slope considered by Chen.\(^3\) It is found that the rate of work due to the soil weight in the region \( ABC \) is

\[
W_{\text{soil}} = \gamma r_0^2 \Omega (f_1 - f_2 - f_3)
\]

where \( f_1, f_2 \) and \( f_3 \) are non-dimensional functions, which are given in Appendix 1.

2.1.2. Rate of work of the active or passive force and the adhesive force. The rate of work of the active or passive force \((P_a \text{ or } P_p)\) and the adhesive force, \( P_{ad} \), can be expressed as follows:

\[
W_{(P_a \text{ or } P_p),P_{ad}} = P_{a,p} r_0 \Omega f_4 + \epsilon r_0^2 \Omega f_5
\]

where \( f_4 \) and \( f_5 \) are non-dimensional functions, which are given in Appendix 1. It should be mentioned that the active or passive force is assumed to act at the lower third of the wall length for the calculation of the coefficients \( K_{ap} \) and \( K_{pp} \). However, the computation of \( K_{ac}, K_{pc}, K_{aq} \) and \( K_{pq} \) is based on the assumption that the point of application of the active or passive force is applied at the middle of the wall length. These hypotheses are in conformity with the classical earth pressure distributions, and allow direct comparison with existing solutions.

2.1.3. Rate of work of the surcharge loading. The rate of work of the surcharge loading \( q \) can be expressed as follows:

\[
W_q = q r_0^2 \Omega f_6
\]

where \( f_6 \) is a non-dimensional function, which is given in Appendix 1.

The total rate of work of the external forces is the summation of these three contributions—that is, equations (1), (2) and (3):

\[
\sum W_{\text{ext}} = W_{\text{soil}} + W_{(P_a \text{ or } P_p),P_{ad}} + W_q
\]

2.2. Rate of energy dissipation

Since no general plastic deformation of the soil is permitted to occur, the energy is dissipated solely at the velocity discontinuity surface BC between the material at rest and the material in motion. The rate of energy dissipation per unit area of a velocity discontinuity can be expressed as

\[
\Omega = \sum W_{\text{ext}}
\]
where $V$ is the velocity that makes an angle $\phi$ with the velocity discontinuity. The total rate of energy dissipation along BC can be expressed as follows:

$$D_{BC} = cr^2_0\Omega f_f$$

where $f_f$ is a non-dimensional function, which is given in Appendix 1.

### 2.3. Energy balance equation

By equating the total rate of work of external forces (equation (4)) to the total rate of energy dissipation (equation (6)), we have

$$\gamma r^2_0(f_1 - f_2 - f_3) + P_{ap} r_0 f_4 + cr^2_0 f_5 + qr^2_0 f_6 = cr^2_0 f_f$$

The energy balance equation of the rotational log-spiral mechanism (i.e. equation (7)) is identical to the moment equilibrium equation about the centre of the log-spiral. It should be emphasised that the log-spiral function has a particular property, that the resultant of the forces $(\sigma \cdot dl)$ and $(\tan \phi \cdot \sigma \cdot dl)$ passes through the pole of the spiral. Hence the moment equilibrium equation of the soil mass in motion about the centre of the log-spiral is independent of the normal stress distribution along the slip surface. Based on equation (7), the active and passive forces can be expressed respectively as follows:

$$p_a = K_a \frac{\gamma l^2}{2} + K_{aq} q l - K_{ac} e l$$

$$p_p = K_p \frac{\gamma l^2}{2} + K_{pq} q l + K_{pc} e l$$

where $K_{ap}$, $K_{aq}$, $K_{apq}$, $K_{ac}$ and $K_{pc}$ are the earth pressure coefficients. The coefficients $K_{ap}$, $K_{aq}$ and $K_{ac}$ represent respectively the effect of soil weight, vertical surcharge loading and cohesion, and the subscripts a and p represent the active and passive cases respectively. These coefficients are given as follows, using the lower sign for the passive case:

$$-K_{ap} = K_{ap} = \frac{d}{r_0} f_1 - f_2 - f_3$$

$$-K_{aq} = K_{pq} = \frac{1}{r_0} f_5$$

For a surcharge loading $q_0$ normal to the ground surface, the active and passive earth pressure coefficients, $K_{aq0}$ and $K_{pq0}$, are given as follows:

$$K_{aq0,pq0} = \pm \frac{1}{r_0} \frac{f_8}{f_4}$$

where $f_8$ is a non-dimensional function, which is given in Appendix 1.

### 3. NUMERICAL RESULTS

The most critical earth pressure coefficients can be obtained by numerical maximisation of the coefficients $K_{aq}$, $K_{ap}$ and $K_{aq0}$ and minimisation of the coefficients $K_{ac}$, $K_{apq}$, $K_{pq0}$, $K_{aq0}$ and $K_{pc}$. These optimisations are made with regard to the parameters $\theta_0$ and $\theta_1$. The procedure can be performed using the optimisation tool available in most spreadsheet software packages. In this paper the Solver optimisation tool of Microsoft Excel has been used. Two computer programs have been developed using Visual Basic for Applications (VBA) to define the active and passive earth pressure coefficients as functions of the two angular parameters $\theta_0$ and $\theta_1$ defined in Fig. 1.

In the following sections, the passive and active earth pressure coefficients obtained from the present analysis are presented and compared with those given by other authors. Then a demonstration of the implementation of earth pressure coefficients as user-defined functions in Microsoft Excel Visual Basic is presented. An illustrative example shows the easy use of spreadsheets in optimisation problems. The paper ends with the presentation of two design tables giving some values of the active and passive earth pressure coefficients for practical use in geotechnical engineering.

#### 3.1. Passive earth pressure coefficients

There are a great many solutions for the passive earth pressure problem in the literature based on

(a) the limit equilibrium method $^4\text{-}^15$
(b) the slip line method $^2\text{-}^21\text{-}^28$
(c) limit analysis theory $^29$

The tendency today in practice is to use the values given by Kérisel and Absi $^{29}$

#### 3.1.1. Comparison with Rankine solution. For the general case of an inclined wall and a sloping backfill ($\alpha/\phi \neq 0$, $\beta/\phi \neq 0$), the Rankine passive earth pressure is inclined at an angle $\alpha$ with the normal to the wall irrespective of the angle of friction at the soil–wall interface, $^{30}$ where

$$\tan \alpha = \frac{\sin(\omega_j + \beta - 2\lambda)\sin \phi}{1 + \sin \phi \cos(\omega_j + \beta - 2\lambda)}$$
and
\[ \sin \omega \beta = \frac{\sin \beta}{\sin \phi} \]

The inclination of the slip surface with the horizontal direction is given as follows:
\[ \xi = \frac{\omega \beta + \beta}{2} + \frac{\pi - \phi}{4} \]

and the coefficient \( K_{py} \) is given by
\[ K_{py} = \frac{\cos(\lambda - \beta)\sin \omega \beta}{\cos \alpha \sin(\omega \beta - \beta)} [1 + \sin \phi \cos(\omega \beta + \beta - 2\lambda)] \]

In order to validate the results of the present analysis, one considers a soil–wall friction angle \( \delta \) equal to the \( \alpha \) value given by equation (14). The numerical solutions obtained by the computer program have shown that, in these cases, the present results are similar to the exact solutions given by Rankine (that is, equations (16) and (17)); the log-spiral slip surface degenerates to a planar surface with radii approaching infinity.

It should be emphasised that the results obtained from the computer program indicate that the coefficient \( K_{pc} \) is related to the coefficient \( K_{pq0} \) by the following relationship (cf. Caquot’s theorem of corresponding states):\[ K_{pc} = \frac{K_{pq0} - \frac{1}{\cos \delta}}{\tan \phi} \]

Also, it should be mentioned that the critical angular parameters \( \theta_0 \) and \( \theta_1 \) obtained from the minimisation of both \( K_{pq0} \) and \( K_{pc} \) give exactly the same critical geometry.

3.1.2. Comparison with Kérisel and Absi. Figures 2 and 3 show the comparison of the present solutions of \( K_{py} \) and \( K_{pq} \) with those of Kérisel and Absi for the case of a vertical wall and an inclined backfill, and for the case of an inclined wall and a horizontal backfill respectively, when \( \phi = 40^\circ \).

For the \( K_{py} \) coefficient, the present results are greater than those of Kérisel and Absi. However, the maximum difference does not exceed 13%. For the \( K_{pq} \) coefficient, the present solutions continue to be greater than those of Kérisel and Absi; a maximum difference of 22% is obtained for the extreme case when \( \phi = 40^\circ \), \( \delta/\phi = 1 \), \( \beta/\phi = 0 \) and \( \lambda = -30^\circ \).

To conclude, the present solutions of \( K_{py} \) and \( K_{pq} \) are greater than the ones given by Kérisel and Absi. However, for practical configurations (\( \phi \leq 40^\circ \), \( 1/3 \leq \delta/\phi \leq 2/3 \), \( \beta/\phi \leq 1/3 \) and \( \lambda = 0^\circ \)), the maximum difference does not exceed 5% for \( K_{py} \) and 7% for \( K_{pq} \).

3.1.3. Comparison with the existing upper-bound solutions. Rigorous upper-bound solutions of the passive earth pressure problem are proposed in the literature by Chen and Rosenfarb and Soubra. Chen and Rosenfarb considered six translational failure mechanisms and showed that the log-sandwich mechanism gives the least (that is, the best) upper-bound solutions. Recently, Soubra considered a translational multi-block failure mechanism and improved significantly the existing upper-bound solutions given by the log-sandwich mechanism for the \( K_{py} \) coefficient, since he obtained smaller upper bounds. The improvement (that is, the reduction relative to Chen and Rosenfarb’s upper-bound solution) attains 21% when \( \phi = 45^\circ \), \( \delta/\phi = 1 \), \( \beta/\phi = 1 \) and \( \lambda = -15^\circ \).

The results of \( K_{py} \) and \( K_{pq} \) given by the present rotational failure mechanism and those given by Soubra using a translational failure mechanism are presented in Fig. 4 for the general case of an inclined wall and a sloping backfill when \( \phi = 45^\circ \) and \( \delta/\phi = 1 \).

For the \( K_{py} \) coefficient, the present upper-bound solutions are smaller (that is, better) than those of Soubra. The improvement (that is, the reduction relative to Soubra’s upper-bound solution) is 27% when \( \phi = 45^\circ \), \( \delta/\phi = 1 \), \( \beta/\phi = 1 \) and \( \lambda = -15^\circ \). For the \( K_{pq} \) coefficient, it should be mentioned that the values obtained by Soubra are identical to those given by Kérisel and Absi and correspond to the exact solutions for a
weightless soil. The present upper-bound solutions of the $K_{pq}$ coefficient are greater than those of Soubra\(^{27}\) and thus overestimate the exact solutions. However, for practical configurations ($C_246 < 40$, $1 = 3 < C_226 < C_246 < 2 = 3$, and $\lambda = 0\$) the maximum difference does not exceed 7.5%.

### 3.2. Active earth pressure coefficients

As in the case of passive earth pressures, the numerical solutions obtained by the computer program have shown that the present model gives the exact solutions proposed by Rankine (when they exist). In these cases, the log-spiral slip surface degenerates to a planar surface with radii approaching infinity. Also, it should be mentioned that the following relationship between $K_{ac}$ and $K_{aq0}$ is valid in the present analysis:

$$K_{ac} = \frac{1}{\cos \delta - K_{aq0}} \frac{\tan \phi}{K_{aq0}}$$

and that the calculation of $K_{aq0}$ and $K_{ac}$ gives exactly the same critical geometry.

#### 3.2.1. Comparison with Kérisel and Absi

Figures 5 and 6 show the comparison of the present solutions of $K_{ap}$ and $K_{aq}$ with those of Kérisel and Absi\(^{29}\) in the case of a vertical wall and an inclined backfill, and in the case of an inclined wall and a horizontal backfill respectively, when $\phi = 45^\circ$ and $\delta/\phi = 1$. 

---

**Fig. 3.** Comparison of present $K_{p}$ and $K_{pq}$ coefficients with those of Kérisel and Absi\(^{29}\) (for inclined wall and horizontal backfill)

**Fig. 4.** Comparison of present $K_{p}$ and $K_{pq}$ coefficients with those of Soubra\(^{27}\)

**Fig. 5.** Comparison of present $K_{ap}$ and $K_{aq}$ coefficients with those of Kérisel and Absi\(^{29}\) (for vertical wall and inclined backfill)
The present results are smaller than those of Kérisel and Absi. For the $K_{sy}$ coefficient, the maximum difference does not exceed 3% when $\lambda \leq 15^\circ$; however, for $\lambda = 20^\circ$ a significant difference is observed. After careful examination of the values proposed by Kérisel and Absi for similar configurations (see for instance their values for $\delta/\phi = 0.66$ or 0), it seems that their $K_{sy}$ value for $\phi = 45^\circ$, $\delta/\phi = 1$, $\beta = 0^\circ$ and $\lambda = 20^\circ$ is not correct. For the $K_{sq}$ coefficient the underestimation does not exceed 8%. The preceding comparisons allow one to conclude that, for practical configurations ($\phi \leq 40^\circ$, $\delta/\phi \leq 1$, $\beta/\phi \geq -1/3$ and $\lambda = 0^\circ$), there is good agreement with the currently used results of Kérisel and Absi for both $K_{sy}$ and $K_{sq}$. The maximum difference does not exceed 3%.

4. IMPLEMENTATION OF USER-DEFINED FUNCTIONS IN VISUAL BASIC FOR APPLICATIONS, AND THE USE OF SOLVER

To implement the functions defining the passive earth pressure coefficients and to run the Solver optimisation tool of Microsoft Excel, one has to follow the following steps (for the active case, use the appropriate equations given in Appendix 1):

(a) Create the user-defined functions shown in Appendix 2. This is done in Microsoft Excel 97 by first clicking Tools/Macro/Visual Basic Editor and then clicking Insert/Module and, in the module sheet, typing ‘Option explicit . . .’; etc. The functions are simple and self-explanatory.

(b) As shown in Fig. 7, cells C5, C6, C7 and C8 are input data that define the mechanical and geometrical parameters $\phi$, $\delta$, $\lambda$ and $\beta$. Cells C12 and C13 contain values of angular parameters of the log-spiral slip surface $\theta_0$ and $\theta_1$. Finally, cell C19 contains the formula to compute the passive earth pressure coefficient $K_{py}$. Arbitrary values were initially entered in cells C12 and C13 for $\theta_0$ and $\theta_1$, say 0-5 for $\theta_0$ and 1-5 for $\theta_1$.

(c) Invoke the Solver tool by clicking Tools/Solver. Fig. 8 shows the Solver dialog box. To calculate the $K_{py}$ coefficient, set the C19 cell ‘equal to’ minimum, ‘by changing’ cells C12 and C13, namely $\theta_0$ and $\theta_1$, ‘subject to’ the constraints that $C13 \geq C12 + 0.0001 (\theta_1 > \theta_0)$, $C12 \leq 3.14 (\theta_0 \leq \pi)$, $C13 \leq 3.14 (\theta_1 \leq \pi)$, $C13 \geq 0 (\theta_1 \geq 0)$ and C19 $\geq 0 (K_{py} \geq 0)$.

If Solver reports a converged solution, one should accept the solution and re_invoke Solver, until it reports it has ‘found a solution’. It should be mentioned that the initial values of $\theta_0$ and $\theta_1$ may influence the ability of the Solver to find a solution. This need for judicious choice of starting values of $\theta_0$ and $\theta_1$ is not a major inconvenience because different starting values can be tried with ease using the proposed spreadsheet approach. The appealing feature of the spreadsheet approach is that once the spreadsheet is set up as shown in Fig. 7, running other problems with different geometry and soil properties merely requires changing the input data (that is, $\phi$, $\delta$, $\beta$ and $\lambda$).

4.1. Illustrative example

Consider the following characteristics: $\phi = 40^\circ$, $\delta/\phi = 2/3$, $\beta/\phi = 0$ and $\lambda = 0^\circ$. Initial values of $\theta_0$ and $\theta_1$ are arbitrarily chosen, say 0-5 for $\theta_0$ and 1-5 for $\theta_1$. Fig. 7 shows the critical coefficient $K_{py} = 12.59$ and the corresponding critical slip surface.
5. DESIGN TABLES

Tables 1 and 2 present the coefficients $K_{pq}$, $K_{pq}$, $K_{pq}$, $K_{pq}$ and $K_{pq}$ obtained from the computer programs for practical use in geotechnical engineering. These values are given for $\phi$ ranging from 20° to 40°, for five values of $\delta/\phi$, for $\lambda = 0^\circ$ and for four values of $\beta/\phi$. For practical configurations, the passive (or active) earth pressure coefficients are given for negative (or positive) $\beta$ values.

6. CONCLUSIONS

A simple method using spreadsheet software has been proposed for computing the active and passive earth pressure coefficients. The proposed method is based on the upper-bound theorem of limit analysis. The failure mechanism is of the rotational type. It is bounded by a log-spiral slip surface. The energy balance equation is shown to be equivalent to the moment equilibrium equation about the centre of the log-spiral. The present approach gives rigorous solutions for the active and passive earth pressures in the framework of the kinematical approach of limit analysis.

Numerical optimisation is performed automatically by a spreadsheet optimisation tool. The implementation of the proposed method has been illustrated using an example. Once the spreadsheet has been set up, the same template can be used for analysing other problems merely by changing the input data. The advantage of this method is its simplicity in use.

Comparison with the currently used solutions of Kérisel and Absi leads to the following conclusions:

(a) For the passive case, the present solutions of $K_{pq}$ and $K_{pq}$ are greater than those given by Kérisel and Absi. However, for practical configurations ($\phi \leq 40^\circ$, $1/3 \leq \delta/\phi \leq 2/3$, $\beta/\phi \leq 1/3$ and $\lambda = 0^\circ$), the maximum difference does not exceed 5% for $K_{pq}$ and 7% for $K_{pq}$.

(b) For the active case, the present solutions of $K_{pq}$ and $K_{pq}$ allow one to conclude that for practical configurations ($\phi \leq 40^\circ$, $\delta/\phi \leq 1/3$, $\beta/\phi \geq 1/3$ and $\lambda = 0^\circ$), there is good agreement with the currently used results of Kérisel and Absi. The maximum difference does not exceed 3%.

On the other hand, the present analysis improves the best upper-bound solutions given in the literature by Soubra for the $K_{pq}$ coefficient. The improvement (that is, the reduction relative to Soubra’s upper-bound solution) is 27% when $\phi = 45^\circ$, $\delta/\phi = 1$, $\beta/\phi = 1$ and $\lambda = 15^\circ$. For the $K_{pq}$ coefficient, the present analysis overestimates the upper-bound solutions given by Soubra. However, for practical configurations ($\phi \leq 40^\circ$, $1/3 \leq \delta/\phi \leq 2/3$, $\beta/\phi \leq 1/3$ and $\lambda = 0^\circ$) the maximum difference does not exceed 7-5%.

Numerical results of the active and passive earth pressure coefficients are given in a tabular form for practical use. The proposed method, being simple and rigorous, may be an attractive alternative to other existing solutions, and can be easily extended to other stability problems in geotechnical engineering.

APPENDIX I

The non-dimensional functions $f_1$, $f_2$, ..., $f_6$ are given as follows, using the lower sign for the passive case:

\[
 f_1 = \pm \frac{\mu e^{\alpha [\theta_0 - \theta_0 \tan \phi]} (3 \tan \phi \cdot \sin \theta_1 \pm \cos \theta_1)}{3(9 \tan^2 \phi + 1)} 
\]

\[
 f_2 = \pm \frac{L}{6r_0} \left( 2 \sin \theta_0 - \frac{2}{r_0} \sin \lambda + \frac{L}{r_0} \cos \beta \right) \cdot \cos (\theta_1 - \beta) \cdot e^{\alpha [\theta_0 - \theta_0 \tan \phi]} 
\]

\[
 f_3 = \pm \frac{1}{6r_0} \sin (\theta_0 - \lambda) \cdot \left( 2 \sin \theta_0 - \frac{l}{r_0} \sin \lambda \right) 
\]

\[
 f_4 = \begin{cases} 
 \cos (\delta + \lambda) & \left( \cos \theta_0 - \frac{l}{3r_0} \cos \lambda \right) \\
 \pm \sin (\delta + \lambda) & \left( \sin \theta_0 - \frac{l}{3r_0} \sin \lambda \right) 
\end{cases} 
\] for $K_1$

\[
 f_5 = \frac{L}{r_0} \tan \phi \sin (\lambda - \theta_0) 
\]

\[
 f_6 = \pm \frac{L}{r_0} \left( -\sin \theta_0 + \frac{l}{r_0} \sin \lambda - \frac{L}{2r_0} \cos \beta \right) 
\]

\[
 f_7 = \mp \frac{1}{2\tan \phi} \left( e^{\alpha [\theta_0 - \theta_0 \tan \phi]} - 1 \right) 
\]

Table 2. Active earth pressure coefficients $K_{ap}$, $K_{aq}$ and $K_{ac}$
\[ f_8 = \frac{L}{r_0} \left( \sin(\beta - \theta_0) + \frac{1}{r_0} \sin(\lambda - \beta) - \frac{1}{2} \frac{L}{r_0} \right) \]

where

\[ L = \frac{e^{\frac{3\theta_1 - \theta_0}{\tan \phi}} \sin(\theta_1 - \cos \theta_1 \cdot \tan \lambda)}{-\sin \theta_0 + \cos \theta_0 \cdot \tan \lambda} \]

\[ \frac{l}{r_0} = \frac{-e^{\frac{3\theta_1 - \theta_0}{\tan \phi}} \cdot \cos(\theta_1 - \beta) + \cos(\theta_0 - \beta)}{\cos(\beta - \lambda)} \]

APPENDIX 2

The user-defined functions for passive earth pressure coefficients coded in Microsoft Excel Visual Basic are as follows:

' Program for evaluation of Kpgamma, Kpc and Kpq for rotational mechanism using log-spiral slip surface
Option Explicit ' All variables must be declared
' Definition of the global constants
Public Const Pi = 3.141592654
' Variables
Public Phi As Double ' internal friction angle of the soil
Public Delta As Double ' angle of friction between soil and wall
Public Lambda As Double ' inclination of the wall
Public Beta As Double ' inclination of the backfill
Public Sl_r0 As Double ' l/r0
Public CL_r0 As Double ' L/r0
' Unknown variables
Public Theta0 As Double ' first unknown angle (in radians)
Public Theta1 As Double ' second unknown angle (in radians)
' Defining the initial values
Sub Define()
    Phi = Cells(5, 3).Value * Pi / 180# ' Values from the cells
    Delta = Cells(6, 3).Value * Pi / 180#
    Lambda = Cells(7, 3).Value * Pi / 180#
    Beta = Cells(8, 3).Value * Pi / 180#
    Theta0 = Cells(12, 3).Value
    Theta1 = Cells(13, 3).Value
    Sl_r0 = (-Exp((Theta1 - Theta0) * Tan(Phi)) * Cos(Theta1 - Beta) - Cos(Theta0 - Beta)) / Cos(Beta - Lambda)
    CL_r0 = (Exp((Theta1 - Theta0) * Tan(Phi)) * (Sin(Theta1) - Cos(Theta1) * Tan(Lambda)) - Sin(Theta0) + Cos(Theta0) * Tan(Lambda)) / (Sin(Beta) * Tan(Lambda) + Cos(Beta))
End Sub
'**********************************************
Function f_1() As Double
    Dim C1#, C2#
