Abstract

This paper describes the HULTECH team participation in Task 3 of SemEval-2014. Four different subtasks are provided to the participants, who are asked to determine the semantic similarity of cross-level test pairs: paragraph-to-sentence, sentence-to-phrase, phrase-to-word and word-to-sense. Our system adopts a unified strategy (general purpose system) to calculate similarity across all subtasks based on word Web frequencies. For that purpose, we define ClueWeb InfoSimba, a cross-level similarity corpus-based metric. Results show that our strategy overcomes the proposed baselines and achieves adequate to moderate results when compared to other systems.

1 Introduction

Similarity between text documents is considered a challenging task. Recently, many works concentrate on the study of semantic similarity for multi-level text documents (Pilehvar et al., 2013), but skipping the cross-level similarity task. In the later, the underlying idea is that text similarity can be considered between pairs of text documents at different granularities levels: paragraph, sentence, phrase or word. One obvious particularity of this task is that text pairs may not share the same characteristics of size, context or structure, i.e., the granularity level.

In task 3 of SemEval-2014, two different strategies have been proposed to solve this issue. On the one hand, participants may propose a combination of individual systems, each one solving a particular subtask. On the other hand, a general purpose system may be proposed, which deals with all the subtasks following the exact same strategy.

In this paper, we describe a language-independent corpus-based general system, which relies on a huge freely available Web collection called Anchor-ClueWeb12 (Hiemstra and Hauff, 2010). In particular, we calculate ClueWeb InfoSimba\footnote{It is a Web version of InfoSimba (Dias et al., 2007).} a cross-level semantic similarity based on word-word frequencies. Indeed, these frequencies are captured by the use of a collocation metric called SCP\footnote{Symmetric Conditional Probability.} (Silva et al., 1999), which has similar properties as the well studied PMI-IR (Turney, 2001) but does not over-evaluate rare events.

Our system outputs a normalized (between 0 and 1) similarity value between two pieces of texts. However, the subtasks proposed in task 3 of SemEval-2014 include a different scoring scale between 0 and 4. To solve this issue, we applied linear, polynomial and exponential regressions as three different runs. Results show that our strategy overcomes the proposed baselines and achieves adequate to moderate results when compared to other systems.

2 System Description

Our system is based on a reduced version of the ClueWeb12 dataset called Anchor ClueWeb12 and an informative attributional similarity measure called InfoSimba (Dias et al., 2007) adapted to this dataset.

2.1 Anchor ClueWeb12 Dataset

The Anchor ClueWeb12 dataset contains 0.5 billion Web pages, which cover about 64% of the total number of Web pages in ClueWeb12. The particularity of Anchor ClueWeb12 is that each Web page is represented by the anchor texts of the links pointing to it in ClueWeb12. Web pages are indexed not on their content but on their references. As such, the size of the index is drastically reduced and the overall results are consistent with full text indexing as discussed in (Hiemstra and Hauff, 2010).

For development purposes, this dataset was indexed in Solr 4.4 on a desktop computer using a batch indexing script. Particularly, each compressed part file of the Anchor ClueWeb12 was uncompressed, preprocessed and indexed in a sequential way using the features of incremental indexing offered by Solr (Smiley and Pugh, 2009).

2.2 InfoSimba

In (Dias et al., 2007), the authors proposed the hypothesis that two texts are similar if they share related (eventually different) constituents. So, their concept of simi-
larity is not any more based on the exact match of constitu-
ents but relies on related constituents (e.g. words). For example, it is clear that the following text pieces
extracted from the sentence-to-phrase subtask are related\(^3\) although they do not share any word.

1. he is a nose-picker
2. an uncouth young man

The InfoSimba similarity measure models this phe-
nomenon evaluating individual similarities between all possible words pairs. Indeed, each piece of text is re-
presented by the vector of its words. So, given two pieces of texts \(X_i\) and \(X_j\), their similarity is defined in
Equation 1 where \(SCP(\ldots)\) is the Symmetric Con-
ditional Probability association measure proposed in
(Silva et al., 1999) and defined in Equation 2.

\[
IS(X_i, X_j) = \frac{1}{pq} \sum_{k=1}^{p} \sum_{l=1}^{q} SCP(w_{ik}, w_{jl}). \quad (1)
\]

\[
SCP(w_{ik}, w_{jl}) = \frac{P(w_{ik}, w_{jl})^2}{P(w_{ik}) \times P(w_{jl})}. \quad (2)
\]

Following the previous example, the In-
foSimba value between the two vectors
\(X_1 = \{"he", "is", "a", "nose-picker"\}\) and
\(X_2 = \{"an", "uncouth", "young", "man"\}\) is an average weight formed by all possible words pairs
associations as illustrated in Figure 1. Note that each
vertex is a word of a \(X_i\) vector and each edge is
weighted by the \(SCP(\ldots)\) value of the connected
words. In particular, each \(w_{ij}\) corresponds to the
word at the \(j^{th}\) position in vector \(X_i\), \(P(\ldots)\) is the
joint probability of two words appearing in the same
document, \(P(\ldots)\) is the marginal probability of any
word appearing in a document and \(p\) (resp. \(q\)) is the
size of the vector \(X_i\) (resp. \(X_j\)).

![Figure 1: Pairs of words evaluated when InfoSimba is calculated.](image)

In the case of task 3 of SemEval-2014, each text
pair is represented by two word vectors for which a
modified version of InfoSimba, ClueWeb InfoSimba,
is computed.

2.3 ClueWeb InfoSimba

The final similarity metric, called ClueWeb InfoSimba
\((CWIS)\), between two pieces of texts is defined in
Equation 3, where \(hits(w)\) returns the number of doc-
uments retrieved by Solr over Anchor ClueWeb12 for
the query \(w\) and \(hits(w_i \land w_j)\) is the number of
documents retrieved when both words are present
simultaneously. In this case, SCP is modified into SCP-IR
similarly as PMI is to PMI-IR, i.e., using hits counts
instead of probability values (see Equation 4).

\[
CWIS(X_i, X_j) = \frac{1}{pq} \sum_{k=1}^{p} \sum_{l=1}^{q} SCP - IR(w_{ik}, w_{jl}). \quad (3)
\]

\[
SCP - IR(w_{ik}, w_{jl}) = \frac{hits(w_{ik} \land w_{jl})^2}{hits(w_{ik}) \times hits(w_{jl})}. \quad (4)
\]

2.4 System Input

The task 3 of SemEval-2014 consists of (1) paragraph-
to-sentence, (2) sentence-to-phrase, (3) phrase-to-word
and (4) word-to-sense subtasks. Before submitting the
pieces of texts to our system, we first performed simple
stop-words removal with the NLTK toolkit (Bird et al.,
2009). Note that in the case of the word-to-sense sub-
task, the similarity is performed over the word itself
and the gloss of the corresponding sense\(^4\).

2.5 Output Values Transformations

The \(CWIS(\ldots)\) similarity metric returns a value be-
tween 0 and 1. However, the subtasks suppose that
each pair must be attributed a score between 0 and 4.
As such, an adequate scale transformation must be
performed. For that purpose, we proposed linear, polyno-

\[\begin{align*}
&\text{linear:} \quad ln(y \sim x), \\
&\text{quadratic:} \quad ln(y \sim x + I(x^2) + I(x^3)), \\
&\text{logistic:} \quad ln(log(y + e) \sim x),
\end{align*}\]

where \(e\) is a small value included to avoid undefined
\(\log\) values. The regression results on the test datasets
are presented in Figure 2.

\(^3\)The score of this pair (#85) in the training set is the max-
imum value 4.

\(^4\)Glosses are obtained from WordNet using the sense id
provided for the task by the organizers.

\(^5\)In the case of linear and exponential, these are mono-
thetic functions therefore ranking-based evaluation metrics
give the same score before and after this step.

\(^6\)In our experiments, this value was set to 0.001.
3 Evaluation and Results

For evaluation purposes, two metrics have been selected by the organizers: Pearson correlation (Pearson, 1895) and Spearman’s rank correlation (Hollander and Wolfe, 1973). Detailed information about the evaluation setup can be found in the task discussion paper (Jurgens et al., 2014).

All results are given in Tables 1 and 2 for each run. Note that the baseline metric is calculated for the longest common string (LCS) and that each regression has been tuned on the training dataset for each one of the four tasks.

First, in almost all cases, the results outperform the baseline. Second, performances show that with a certain amount of information (longer pieces of texts), interesting results can be obtained. However, when the size decreases, the performance diminishes and extra information is certainly needed to better capture the semantics between two pieces of text. Third, the polynomial regression provides better results for the Pearson correlation evaluation, while for the Rho test, linear and polynomial regressions get the lead. Note that this situation depends on the data distribution and cannot be seen as a conclusive remark. However, it is certainly an important subject of study for our unsupervised methodology.

Another key point is that training examples were used only for evaluation purposes. In the case of Spearman’s rank correlation, the linear and exponential transformations obviously show exact same values (See Table 2).

4 Conclusions

In this paper, we proposed a general purpose system to deal with cross-level text similarity. The aim of our research was to push as far as possible the limits of language-independent corpus-based solutions in a general context of text similarity. We were also concerned with reproducibility and as such we exclusively used publicly available datasets and tools. The results clearly show the limits of a simple solution based on word statistics. Nevertheless, the framework can easily be empowered with the straightforward introduction of more competitive resources.
