HAL is a multi-disciplinary open access archive for the deposit and dissemination of scientific research documents, whether they are published or not. The documents may come from teaching and research institutions in France or abroad, or from public or private research centers.

L’archive ouverte pluridisciplinaire HAL, est destinée au dépôt et à la diffusion de documents scientifiques de niveau recherche, publiés ou non, émanant des établissements d’enseignement et de recherche français ou étrangers, des laboratoires publics ou privés.
Repulsive Gravitational Force Field

A method is proposed in this paper to generate a repulsive gravitational force field, which can strongly repel material particles, while creating a gravitational shielding that can nullify the momentum of incident particles (including photons). By nullifying the momentum of the particles and photons, including in the infrared range, this force field can work as a perfect thermal insulation. This means that, a spacecraft with this force field around it, cannot be affected by any external temperature and, in this way, it can even penetrate (and to exit) the Sun without being damaged or to cause the death of the crew. The repulsive force field can also work as a friction reducer with the atmosphere (between an aeronave and the atmosphere), which allows traveling with very high velocities through the atmosphere without overheating the aeronave. The generation of this force field is based on the reversion and intensification of gravity by electromagnetic means.

Key words: Quantum Gravity, Gravitation, Gravity Control, Repulsive Force Field.

1. Introduction

The Higgs field equations are [1]:

\[ \nabla \mu \nabla^\mu \phi_a + \frac{1}{2} \left( m^2 - f^2 \phi_a \phi_a \right) \phi_a = 0 \quad (1) \]

Assuming that mass \( m_0 \) is the gravitational mass \( m_g \), then we can say that in Higgs field the term \( m_g^2 < 0 \) arises from a product of positive and negative gravitational masses \( \left(m_g \right) \left(-m_g \right) = -m_g^2 \), however it is not an imaginary particle. Thus, when the Higgs field is decomposed, the positive gravitational mass is called particle, and spontaneous gives origin to the mass; the negative gravitational mass is called “dark matter”. The corresponding Goldstone boson is \( \left(+m_g \right) + \left(-m_g \right) = 0 \), which is a symmetry, while the Higgs mechanism is spontaneously broken symmetry. Thus, the existence of the Higgs bosons [2] implies in the existence of positive gravitational mass and negative gravitational mass.

On the other hand, the existence of negative gravitational mass implies in the existence of repulsive gravitational force. Both in the Newton theory of gravitation and in the General Theory of Relativity the gravitational force is exclusively attractive one. However, the quantization of gravity shows that the gravitational forces can also be repulsive [3].

Based on this discovery, here we describe a method to generate a repulsive gravitational force field that can strongly repel material particles and photons of any frequency. It was developed starting from a process patented in July, 31 2008 (BR Patent Number: PI0805046-5) [4].

2. Theory

In a previous paper [5] it was shown that, if the weight of a particle in a side of a lamina is \( \bar{P} = m_g \bar{g} \) (\( \bar{g} \) perpendicular to the lamina), then the weight of the same particle, in the other side of the lamina is \( \bar{P'} = \chi m_g \bar{g} \), where \( \chi = \frac{m_g}{m_{i0}} \) (\( m_g \) and \( m_{i0} \) are respectively, the gravitational mass and the inertial mass of the lamina). Only when \( \chi = 1 \), the weight is equal in both sides of the lamina. The lamina works as a Gravitational Shielding. This is the Gravitational Shielding effect. Since \( P' = \chi P = \chi m_g g = m_g (\chi g) \), we can consider that \( m'_g = \chi m_g \) or that \( g' = \chi g \).

If we take two parallel gravitational shieldings, with \( \chi_1 \) and \( \chi_2 \) respectively, then the gravitational masses become: \( m_{g1} = \chi_1 m_g \), \( m_{g2} = \chi_2 m_{g1} = \chi_1 \chi_2 m_g \), and the gravity will be given by: \( g_1 = \chi_1 g \), \( g_2 = \chi_2 g_1 = \chi_1 \chi_2 g \).

In the case of multiples gravitational shieldings, with \( \chi_1, \chi_2, \ldots, \chi_n \), we can write that, after the \( n \)th gravitational shielding the gravitational mass, \( m_{gn} \), and the gravity, \( g_n \), will be given by

\[ m_{gn} = \chi_1 \chi_2 \chi_3 \ldots \chi_n m_g, \quad g_n = \chi_1 \chi_2 \chi_3 \ldots \chi_n g \quad (2) \]

This means that, \( n \) superposed gravitational shieldings with different \( \chi_1, \chi_2, \chi_3, \ldots, \chi_n \) are equivalent to a single gravitational shielding with \( \chi = \chi_1 \chi_2 \chi_3 \ldots \chi_n \).
Fig. 1 – Plane and Spherical Gravitational Shieldings. When the radius of the gravitational shielding (b) is very small, any particle inside the spherical crust will have its gravitational mass given by $m'_g = \chi m_g$, where $m_g$ is its gravitational mass out of the crust.

Fig. 2 – The gravity acceleration in both sides of the gravitational shielding.

Fig. 3 – Gravitational Shielding (GS). If the gravity at a side of the GS is $\vec{g}$ (perpendicular to the lamina) then the gravity at the other side of the GS is $\chi \vec{g}$. Thus, in the case of $\vec{g}$ and $\chi \vec{g}$ (see figure above) the resultant gravity at each side is $\vec{g} + \chi \vec{g}$ and $\chi \vec{g}$, respectively.

The extension of the shielding effect, i.e., the distance at which the gravitational shielding effect reach, beyond the gravitational shielding, depends basically of the magnitude of the shielding's surface. Experiments show that, when the shielding's surface is large (a disk with radius $a$) the action of the gravitational shielding extends up to a distance $d \cong 20a$ [6]. When the shielding's surface is very small the extension of the shielding effect becomes experimentally undetectable.

Fig. 4 - When the shielding's surface is large the action of the gravitational shielding extends up to a distance $d \cong 20a$ (A). When the shielding's surface is very small the extension of the shielding effect becomes experimentally undetectable (B).

The quantization of gravity shows that the gravitational mass $m_g$ and inertial mass $m_i$ are correlated by means of the following factor [3]:
\[ \chi = \frac{m_g}{m_{i0}} = \left\{ 1 - 2 \left[ \frac{1 + \left( \frac{\Delta p}{m_{i0}c} \right)^2}{1 + \left( \frac{\Delta E}{m_{i0}c^2 n_r} \right)^2} - 1 \right] \right\} \]  

(3)

where \( m_{i0} \) is the rest inertial mass of the particle and \( \Delta p \) is the variation in the particle’s kinetic momentum; \( c \) is the speed of light.

In general, the momentum variation \( \Delta p \) is expressed by \( \Delta p = F \Delta t \) where \( F \) is the applied force during a time interval \( \Delta t \). Note that there is no restriction concerning the nature of the force \( F \), i.e., it can be mechanical, electromagnetic, etc.

For example, we can look on the momentum variation \( p \Delta \) as due to absorption or emission of electromagnetic energy. In this case, substitution of \( \Delta p = \Delta E/v = \Delta E|c/v|v = \Delta E|c| \) into Eq. (1), gives

\[ \chi = \frac{m_g}{m_{i0}} = \left\{ 1 - 2 \left[ \frac{1 + \left( \frac{\Delta E}{m_{i0}c^2 n_r} \right)^2}{1 + \left( \frac{\Delta E}{m_{i0}c^2 n_r} \right)^2} - 1 \right] \right\} \]  

(4)

By dividing \( \Delta E \) and \( m_{i0} \) in Eq. (4) by the volume \( V \) of the particle, and remembering that, \( \Delta E/V = W \), we obtain

\[ \chi = \frac{m_g}{m_{i0}} = \left\{ 1 - 2 \left[ \frac{1 + \left( \frac{W}{\rho c^2 n_r} \right)^2}{1 + \left( \frac{W}{\rho c^2 n_r} \right)^2} - 1 \right] \right\} \]  

(5)

where \( \rho \) is the matter density (\( \text{kg/m}^3 \)).

Based on this possibility, we have developed a method to generate a repulsive gravitational force field that can strongly repel material particles.

In order to describe this method we start considering figure 5, which shows a set of spherical gravitational shieldings, with \( \chi_1, \chi_2, \ldots, \chi_n \), respectively. When these gravitational shieldings are deactivated, the gravity generated is

\[ g = -GM_{g0}/r^2 \approx -GM_{i0}/r^2 \]

where \( m_{i0} \) is the total inertial mass of the \( n \) spherical gravitational shieldings. When the system is activated, the gravitational mass becomes

\[ m_g = (\chi_1, \chi_2, \ldots, \chi_n)m_{i0} \]

and the gravity is given by

\[ g' = (\chi_1, \chi_2, \ldots, \chi_n)g = -(\chi_1, \chi_2, \ldots, \chi_n)GM_{i0}/r^2 \]  

(6)

If we make \( (\chi_1, \chi_2, \ldots, \chi_n) \) negative (\( n \) odd) the gravity \( g' \) becomes repulsive, producing a pressure \( p \) upon the matter around the sphere. This pressure can be expressed by means of the following equation

\[ p = \frac{F}{S} = \frac{m_{i0}(\text{matter})g'}{S} = \frac{\rho_{(\text{matter})}S\Delta g'}{S} = \rho_{(\text{matter})}\Delta g' \]  

(7)

Substitution of Eq. (6) into Eq. (7), gives

\[ p = -(\chi_1, \chi_2, \ldots, \chi_n)\rho_{(\text{matter})}\Delta x(GM_{i0}/r^2) \]  

(8)

If the matter around the sphere is only the atmospheric air (\( p_a = 1.013 \times 10^5 \text{N/m}^2 \)), then, in order to expel all the atmospheric air from the inside the belt with \( \Delta x \) - thickness (See Fig. 5), we must have \( p > p_a \). This requires that

\[ (\chi_1, \chi_2, \ldots, \chi_n) > \frac{p_a p^2}{\rho_{(\text{matter})}\Delta x GM_{i0}} \]  

(9)

Satisfied this condition, all the matter is expelled from this region, except the
Continuous Universal Fluid (CUF), which density is $\rho_{\text{CUF}} \approx 10^{-23}$ kg m$^{-3}$ [7].

The density of the Universal Quantum Fluid is clearly not uniform along the Universe. At supercompressed state, it gives origin to the known matter (quarks, electrons, protons, neutrons, etc). Thus, the gravitational mass arises with the supercompression state. At the normal state (free space, far from matter), the local inertial mass of Universal Quantum Fluid does not generate gravitational mass, i.e., $\chi = 0$. However, if some bodies are placed in the neighborhoods, then this value will become greater than zero, due to proximity effect, and the gravitational mass will have a non-null value. This is the case of the region with $\Delta x$-thickness, i.e., in spite of all the matter be expelled from the region, remaining in place just the Universal Quantum Fluid, the proximity of neighboring matter makes non-null the gravitational mass of this region, but extremely close to zero, in such way that, the value of $\chi = m_i/m_0$ is also extremely close to zero ($m_0$ is the inertial mass of the Universal Quantum Fluid in the mentioned region).

Another important equations obtained in the quantization theory of gravity is the new expression for the momentum $q$ and gravitational energy of a particle with gravitational mass $M_g$ and velocity $v$, which is given by [3]

\begin{equation}
\dot{q} = M_g \dot{v} \tag{10}
\end{equation}

\begin{equation}
E_g = M_g c^2 \tag{11}
\end{equation}

where $M_g = m_i \sqrt{1-v^2/c^2}$; $m_i$ is given by Eq.(1), i.e., $m_i = \chi m_i$. Thus, we can write

\begin{equation}
M_g = \frac{\chi m_i}{\sqrt{1-v^2/c^2}} = \chi M_i \tag{12}
\end{equation}

Substitution of Eq. (12) into Eq. (11) and Eq. (10) gives

\begin{equation}
E_g = \chi M_i c^2 \tag{13}
\end{equation}

\begin{equation}
\dot{q} = \chi M_i \dot{v} = \frac{\dot{v}}{c} \frac{\hbar}{\lambda} \tag{14}
\end{equation}

For $v = c$, the momentum and the energy of the particle become infinite. This means that a particle with non-null mass cannot travel with the light speed. However, in Relativistic Mechanics there are particles with null mass that travel with the light speed. For these particles, Eq. (14) gives

\begin{equation}
q = \frac{\hbar}{\lambda} \tag{15}
\end{equation}

Note that only for $\chi = 1$ the Eq. (15) is reduced to the well-known expressions of DeBroglie $(q = h/\lambda)$.

Since the factor $\chi$ can be strongly reduced under certain circumstances (See Eq.(1)), then according to the Eqs. (13) and (14), the gravitational energy and the momentum of a particle can also be strongly reduced. In the case of the region with $\Delta x$-thickness, where $\chi$ is extremely close to zero, the gravitational energy and the momentum of the material particles and photons become practically null.

By nullifying the gravitational energy and the momentum of the particles and photons, including in the infrared range, this force field can work as a perfect thermal insulation. This means that, a spacecraft with this force field around it, cannot be affected by any external temperature and, in this way, it can even penetrate (and to exit) the Sun without being damaged or to cause the death of the crew. The repulsive force field can also work as a friction reducer with the atmosphere (between an aeronave and the atmosphere), which allows traveling with very high velocities through the atmosphere without overheating the aeronave.

Considering Eq. (8), for $p = p_s$ at $r = 6m$, we can write that

\begin{equation}
\left(\chi_1 \chi_2 \cdots \chi_n\right) = -\frac{36 p_s}{\Delta x \rho_{\text{matter}} GM_{0s}} \tag{16}
\end{equation}

The gravitational shieldings $(1, 2, \ldots, n)$ can be made very thin, in such way that the total inertial mass of them, for example in the case of $r_s \approx 4.9m$, can be assumed as $M_{0s} \approx 5000kg$. Thus, for $\Delta x = 1m$ and $\rho_{\text{matter}} = 1.2kg \cdot m^{-3}$, Eq. (16) gives

\begin{equation}
\left(\chi_1 \chi_2 \cdots \chi_n\right) = -9.1 \times 10^{12} m \tag{17}
\end{equation}

By making $\chi_1 = \chi_2 = \ldots = \chi_n$, then, for $n = 7$, we obtain the following value

\begin{equation}
\chi_1 = \chi_2 = \ldots = \chi_7 = -71.00 \tag{22}
\end{equation}
It is relatively easy to build the set of spherical gravitational shieldings with these values. First we must choose a convenient material, with density $\rho$ and refraction index $n_r$, in such way that, by applying an electromagnetic field $E$ sufficient intense $W = \varepsilon_0 E^2$, we can obtain, according to Eq. (5), the values given by Eq. (22).

Since in the region with $\Delta x$ - thickness, the value of $\chi$ is extremely close to zero, we can conclude that the gravitational mass of the spacecraft, which is given by $m_{gs} = \chi (\chi_1 \chi_2 \ldots \chi_n) m_{i0}$, becomes very small. This makes possible to the spacecraft acquire strong accelerations, even when subjected to small thrusts $(a = F/m_{gs})$. On the other hand, with a small gravitational mass, the weight of the spacecraft will be also small.

Note that the Gravitational Repulsive Force Field aggregates new possibilities to the Gravitational Spacecraft, previously proposed [8], while showing that the performance of this spacecraft goes much beyond the conventional spacecrafts.
