Abstract. From a spectral method combined with a predictor-corrector scheme, we numerically study the behavior in time of solutions of the three-dimensional generalized Kadomtsev-Petviashvili equations regularized using the BBM trick. The solution no longer blows up and the solitonic behavior is observed.

Keywords. 3D-KP equations, BBM equation, spectral method, predictor-corrector scheme, dispersion, solitonic behavior, transverse instability

MS Codes. 35B05, 35B35, 35Q53, 65L05, 65M70

Introduction

The Kadomtsev-Petviashvili equations (KP) in three-dimensional space

$$u_t + u_x + uu_x + u_{xxx} + a\partial_x^{-1}u_{yy} + b\partial_x^{-1}u_{zz} = 0 \quad (1)$$

is used to describe the Bose-Einstein condensation [5], or electromagnetic waves in a ferromagnetic medium [14]. Here ∂_x^{-1} denotes the anti-derivative, defined such that $\widehat{\partial_x^{-1}u}(\xi_1, \xi_2, \xi_3) := \widehat{u}(\xi_1, \xi_2, \xi_3)/(\mathrm{i}\xi_1)$, and $\widehat{u}$ represents the Fourier transform of u , the constants a, b are normalized to ± 1 .

Using the Benjamin-Bona-Mahony trick [3] (the change of variables $\varepsilon^{-1}u(\varepsilon^{-1/2}x, \varepsilon^{-1}y, \varepsilon^{-1}z, \varepsilon^{-1/2}t)$ is applied, with ε small), we can replace u_x by $-u_t + O(\varepsilon)$ in (1) to find the so-called regularized KP equations (or the BBM equation)

$$u_t + u_x + uu_x - u_{xxt} + a\partial_x^{-1}u_{yy} + b\partial_x^{-1}u_{zz} = O(\varepsilon). \quad (2)$$

In this paper, we are concerned with the regularized generalized KP equations in three-dimensional space

$$u_t + u_x + u^p u_x - u_{xxt} + a\partial_x^{-1}u_{yy} + b\partial_x^{-1}u_{zz} = 0, \quad (3)$$

where $p \geq 1$.

Recall that the mass

$$\int_{\mathbb{R}^3} u^2(x, y, z, t) + u_x^2(x, y, z, t) dx dy dz,$$

is conserved by the flow associated with (3). Some theoretical results concerning the behavior of solutions of (1) have been recently established, in particular the existence of solitary waves [6, 7] and the blow-up in finite time [15, 16, 24]. Many theoretical and numerical works related with Kadomtsev-Petviashvili equations and its regularized version in dimension two can be found in the literature ([4, 8, 11, 13, 24, 25, 27, 28] and references therein). Few literatures are concerning the dimension three, therefore numerical simulations are of interest [12, 17, 26, 30, 32]. We recently studied the numerical behavior of the solutions of (1), and observed three phenomenons : the blow-up in finite time, the dispersion and the solitonic behavior [10].

The aim of this paper consists in inspecting numerically the behavior of the solution of (3). We observe the regularizing effect of (3): the blow-up in finite time of solutions does no longer occur.

This paper is subdivided into four sections. In Section 1, we discretize the Cauchy problem associated with (3), by combining a spectral method for the space discretization and a predictor-corrector scheme for the time discretization. Sections 2, 3 and 4 systematically deal with numerical simulations.

We study in Section 2 the propagation, based on (3), of localized initial data. The numerical inspections show in the contexts where $p \geq 1, a = b = -1$, and $p \geq 3, a = b = 1$ or $ab = -1$, the l^∞ -norm of the discrete solution of (3) is first perturbed and then is stabilized. This is defined as the solitonic behavior. This state, for which the amplitude of the wave remains constant, is a intermediary between the dispersion due to the linearity (the amplitude of the wave decreases and the wave is broken down) and the blow-up in finite time due to the non-linearity. Furthermore, soliton is a particular solution which is translated at a constant velocity without loss of shape. Concerning (1), the numerical solutions blow up in finite time in the same contexts [10].

In the two next sections, we are concerned with the numerical investigation of the transverse instabilities, we aim to characterize the unstable modes [1, 2, 19, 20, 21, 22, 23, 29]. The unstable modes are obtained from the linearized equation around Φ_c , a solitary wave, as

$$u(x, y, t) = \Phi_c(x - ct) + \varepsilon e^{\sigma t + i \frac{2\pi y}{\lambda_y}} \tilde{u}(x),$$

with $\lambda_y > 0, \text{Re}(\sigma) > 0, \tilde{u} \in L^2(\mathbb{R})$. The line-soliton

$$\Phi_c(x) = \left(\frac{(p+1)(p+2)}{2} c \right)^{1/p} \text{sech}^{2/p} \left(\frac{p}{2} x \right),$$

is considered in Section 3 and we study the solution of (3) with the initial datum:

$$u_0(x, y, z) := \Phi_{c(y,z)}(x),$$

where $c(y, z) := c(1 + \varepsilon \cos(2\pi y/\lambda_y + 2\pi z/\lambda_z))$ is a perturbation of the velocity of the line-soliton, in an infinitesimal way in the y and z -directions, $\lambda_y, \lambda_z > 0$, and $\varepsilon > 0$ is a fixed small value.

When $p \geq 2$, $a = b = -1$, or $ab = -1$, there exist two critical transverse wavelengths $0 < \lambda_c^1 \ll \lambda_c^2$, depending only on c , such that the discrete solution of (3) with such an initial datum u_0 is unstable under the flow of (3) if $\lambda_c^1 < \lambda_y < \lambda_c^2$ or $\lambda_c^1 < \lambda_z < \lambda_c^2$.

The study of the transverse instability in the z -direction is done in Section 4, by considering as initial datum the profile of the Zaitsev traveling waves [31], which exists for $p = 1$ and $a = -1$:

$$u_0(x, y, z) := \psi_{c(z)}(x, y),$$

$$\psi_c(x, y) = 12\alpha^2 c \frac{1 - \beta \cosh(\alpha x) \cos(\delta y)}{(\cosh(\alpha x) - \beta \cos(\delta y))^2}, \beta = \sqrt{1 - \frac{3c\alpha^4}{\delta^2}}, 3c\alpha^4 < \delta^2, \alpha^2 + \frac{\delta^2}{c\alpha^2} = 1.$$

The velocity is here perturbed in the z -direction; $c(z) := c(1 + \varepsilon \cos(2\pi z/\lambda_z))$, $\lambda_z > 0$, and $\varepsilon > 0$ a fixed small value. The wavelength λ_z translates the instability by transverse perturbations in the sense that, when $b = -1$, there exist two critical transverse wavelengths $0 < \lambda_c^1 \ll \lambda_c^2$, depending only on c , such that the solution of (3) with u_0 as initial datum behaves like a soliton, not close to the initial datum if $\lambda_c^1 < \lambda_z < \lambda_c^2$. The solution is hence unstable.

1 Numerical discretizations

Recall that the initial value problem is globally in time well-posed in dimension two [4, 25]:

Theorem 1.1 [25] *There exists a functional space continuously $\mathcal{X}$ embedded in $\mathcal{C}(\mathbb{R}; H)$, with $H \subset L^2(\mathbb{R}^2)$ equipped with the norm*

$$\|u\|_H = (\|u\|_{L^2}^2 + \|u_x\|_{L^2}^2)^{1/2},$$

such that for any $u_0 \in H$, there exists a unique global in time solution $u \in \mathcal{X}$ with u_0 as initial datum.

In [4], the global well-posedness is provided in the space

$$\{u, u_x, u_y, u_{xx}, \partial_x^{-1} u_y \in L^2(\mathbb{R}^2)\}.$$

Let us consider the Cauchy problem based on (3), where u_0 denotes the initial datum:

$$u(x, y, z, 0) := u_0(x, y, z),$$

with the following functional settings:

$$\{u, u_x, u_y, u_z, u_{xx}, u_{yy}, u_{zz}, \partial_x^{-1} u_y, \partial_x^{-1} u_z, \partial_x^{-2} u_{yy}, \partial_x^{-2} u_{zz} \in L^2(\mathbb{R}^3)\}.$$

By combining a spectral approach with a predictor-corrector scheme, we discretize here the Cauchy problem based on (3).

1.1 Spectral approach

Spectral methods are very suitable to the discretization of equations such as (3), the non-linearity and the anti-derivative appearing in (3) being easily treated.

For $(\xi_1, \xi_2, \xi_3) \in \mathbb{R}^3$, and $t \geq 0$, we use the notation

$$\hat{u}(\xi_1, \xi_2, \xi_3, t) := \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} u(x, y, z, t) e^{-i(\xi_1 x + \xi_2 y + \xi_3 z)} dx dy dz.$$

By applying this Fourier transform to the considered Cauchy problem, it follows that the singularity for $\xi_1 = 0$ needs to be overcome. Looking moreover for solutions of (3) such that u , u^{p+1} and $u_t \in L^1(\mathbb{R}^3) \cap L^2(\mathbb{R}^3)$, we notice that $\forall (\xi_2, \xi_3) \in \mathbb{R}^2, \forall t > 0$,

$$\lim_{\xi_1 \rightarrow 0} \widehat{u}(\xi_1, \xi_2, \xi_3, t) = 0, \quad \lim_{\xi_1 \rightarrow 0} \frac{\widehat{u}(\xi_1, \xi_2, \xi_3, t)}{\xi_1} = 0,$$

provided that

$$\widehat{u}_0(0, \xi_2, \xi_3) = 0, \quad \lim_{\xi_1 \rightarrow 0} \frac{\widehat{u}_0(\xi_1, \xi_2, \xi_3)}{\xi_1} = 0. \quad (4)$$

Indeed, by integrating over $\mathbb{R}$ with respect to x , we have

$$\int_{-\infty}^{+\infty} u_{yy}(x, y, z, t) + u_{zz}(x, y, z, t) dx = 0.$$

Since u vanishes at infinity, we obtain for all time $t \in \mathbb{R}$

$$\int_{-\infty}^{+\infty} u(x, y, z, t) dx = 0 = \int_{-\infty}^{+\infty} u_0(x, y, z) dx.$$

Therefore, integrate over $\mathbb{R}$ with respect to x provides

$$\int_{-\infty}^{+\infty} \partial_x^{-1} u_{yy}(x, y, z, t) + \partial_x^{-1} u_{zz}(x, y, z, t) dx = 0, \quad \text{and} \quad \int_{-\infty}^{+\infty} \partial_x^{-1} u(x, y, z, t) dx = 0.$$

In view of numerical computations in a bounded and periodised domain Ω , we now consider (3) in $[-K, K] \times [-L, L] \times [-M, M] =: \Omega$, where $K, L, M > 0$ are fixed values allowing us to express the relations (4) as below

$$\left\{ \begin{array}{l} \int_{-M}^M \int_{-L}^L e^{-i(\xi_2 y + \xi_3 z)} \left(\int_{-K}^K u_0(x, y, z) dx \right) dy dz = 0, \\ \int_{-M}^M \int_{-L}^L e^{-i(\xi_2 y + \xi_3 z)} \left(\int_{-K}^K \int_{-K}^x u_0(x_1, y, z) dx_1 dx \right) dy dz = 0. \end{array} \right. \quad (5)$$

Let us consider now the discrete Fourier basis consisting of trigonometric polynomial functions

$$e^{ik \frac{\pi}{K} x} e^{il \frac{\pi}{L} y} e^{im \frac{\pi}{M} z}; \quad i^2 = -1, \quad -\frac{N_x}{2} \leq k \leq \frac{N_x}{2} - 1, \quad -\frac{N_y}{2} \leq l \leq \frac{N_y}{2} - 1, \quad -\frac{N_z}{2} \leq m \leq \frac{N_z}{2} - 1,$$

where $N_x, N_y, N_z \in 2\mathbb{N}^*$ represent the numbers of modes. Let us set $N_x = 2K/\Delta x$, $N_y = 2L/\Delta y$ and $N_z = 2M/\Delta z$, where $\Delta x, \Delta y, \Delta z > 0$. For any non periodic scalar function u , locally summable, we denote by $u_{K,L,M}$ the function equal to u in Ω and extended outside of Ω as a periodic function of period equal to $2K$ in the x -direction, $2L$ in the y -direction, $2M$ in the z -direction. The expression of $u_{K,L,M}$ in the considered discrete basis is as follows,

$$u_{K,L,M}(x, y, z) = \sum_{k=-\frac{N_x}{2}, l=-\frac{N_y}{2}, m=-\frac{N_z}{2}}^{\frac{N_x}{2}-1, \frac{N_y}{2}-1, \frac{N_z}{2}-1} \widehat{u}(k \frac{\pi}{K}, l \frac{\pi}{L}, m \frac{\pi}{M}) e^{ik \frac{\pi}{K} x} e^{il \frac{\pi}{L} y} e^{im \frac{\pi}{M} z},$$

with

$$\widehat{u}(k \frac{\pi}{K}, l \frac{\pi}{L}, m \frac{\pi}{M}) = \frac{1}{(2K)(2L)(2M)} \int_{-K}^K \int_{-L}^L \int_{-M}^M u(x, y, z) e^{-ik \frac{\pi}{K} x} e^{-il \frac{\pi}{L} y} e^{-im \frac{\pi}{M} z} dx dy dz.$$

We are then concerned with a system of $N_x \times N_y \times N_z$ ordinary differential equations and $N_x \times N_y \times N_z$ unknowns: for each triplet (ξ_1, ξ_2, ξ_3) , find $\widehat{u}(\xi_1, \xi_2, \xi_3, t)$ satisfying

$$\begin{cases} (1 + \xi_1^2)\widehat{u}_t(\xi_1, \xi_2, \xi_3, t) + i\xi_1 \widehat{\frac{u^{p+1}}{p+1}}(\xi_1, \xi_2, \xi_3, t) + i(\xi_1 + a\xi_2^2/\xi_1 + b\xi_3^2/\xi_1)\widehat{u}(\xi_1, \xi_2, \xi_3, t) = 0, & \forall t > 0, \\ \widehat{u}(0, \xi_2, \xi_3, t) = \widehat{u}_0(0, \xi_2, \xi_3), & \forall t > 0, \\ \widehat{u}(\xi_1, \xi_2, \xi_3, 0) = \widehat{u}_0(\xi_1, \xi_2, \xi_3), \end{cases} \quad (6)$$

where

$$\begin{cases} \xi_1 = k \frac{\pi}{K}, \quad \xi_2 = l \frac{\pi}{L}, \quad \xi_3 = m \frac{\pi}{M}, \\ -\frac{N_x}{2} \leq k \leq \frac{N_x}{2} - 1, \quad -\frac{N_y}{2} \leq l \leq \frac{N_y}{2} - 1, \quad -\frac{N_z}{2} \leq m \leq \frac{N_z}{2} - 1, \end{cases} \quad (7)$$

and the datum u_0 is subject to (5).

1.2 Time discretization

In view of efficient numerical computations on long time intervals, we consider predictor-corrector method [18]. Also, in view of flexible numerical implementations, we restrict ourselves to one-step schemes.

Let $\Delta t > 0$ be the step of the time discretization, and set $t_n = n\Delta t$. For $n \in \mathbb{N}$, we denote by $\widehat{u}_n$ an approximation of $\widehat{u}(\xi_1, \xi_2, \xi_3, t_n)$ and by u_n an approximation of $u(x, y, z, t_n)$, where $(x, y, z) \in \Omega$. The method we consider for solving (6) - (7) consists of combining the explicit Euler method for the predictor and the Crank-Nicolson method for the corrector. The resulting scheme is a predictor-corrector method and is of order two with respect to the time step [18] under suitable regularities of the solution of (6) - (7).

By denoting by $m \geq 1$ a maximal number of iterations, the algorithm considered for solving (6) - (7) is described as follows:

- Set $\widehat{u}_{0,m} := \dots := \widehat{u}_{0,1} := \widehat{u}_{0,0} := \widehat{u}_0$.
- For $n = 0, 1, \dots$, compute:

$$\widehat{u}_{n+1,0} := \widehat{u}_{n,m} - \frac{i\Delta t}{1 + \xi_1^2} \left(\xi_1 \widehat{\frac{u_{n,m}^{p+1}}{p+1}} + (\xi_1 + a\xi_2^2/\xi_1 + b\xi_3^2/\xi_1)\widehat{u}_{n,m} \right),$$

- For $r = 0, 1, \dots, m-1$,

$$\begin{aligned} \widehat{u}_{n+1,r+1} := \widehat{u}_{n,m} - \frac{i\Delta t}{2(1 + \xi_1^2)} & \left(\xi_1 \widehat{\frac{u_{n+1,r}^{p+1}}{p+1}} + (\xi_1 + a\xi_2^2/\xi_1 + b\xi_3^2/\xi_1)\widehat{u}_{n+1,r} + \xi_1 \widehat{\frac{u_{n,m}^{p+1}}{p+1}} \right. \\ & \left. + (\xi_1 + a\xi_2^2/\xi_1 + b\xi_3^2/\xi_1)\widehat{u}_{n,m} \right). \end{aligned} \quad (8)$$

The iterations are stopped in one of the two following cases:

- when $\|u_{n+1,r+1} - u_{n+1,r}\|_{l^2(\Omega)} / \|u_{n+1,0}\|_{l^2(\Omega)} \leq \tau$, with $\tau > 0$ a fixed tolerance. We then set $u_{n+1} := u_{n+1,r+1}$;
- or when $r = m-1$. Here, we set $u_{n+1} := u_{n+1,m}$. We mention that the step Δt can be reduced in this case, in order to improve the previous relative error.

This algorithm provides the solution $\widehat{u}_n(\xi_1, \xi_2, \xi_3)$, where $\xi_1 \neq 0$, ξ_2, ξ_3 are defined as in (7), and where we consider:

- For $n = 1, 2, \dots$,
 $\widehat{u}_n(0, \xi_2, \xi_3) := \widehat{u}_0(0, \xi_2, \xi_3).$

Remark 1.1 *A practical way to choose a suitable (initial) step Δt in the previous algorithm is the one involving the parameters $\Delta y, \Delta z$ as follows: for $\Omega = [-K, K] \times [-L, L] \times [-M, M]$,*

$$\Delta t < \frac{4}{1 + (K/\Delta y)^2 + (K/\Delta z)^2 + \|u_n\|_{L^\infty(\Omega)}^p}. \quad (9)$$

Indeed, since from (8),

$$\begin{aligned} \widehat{u}_{n+1, r+1} - \widehat{u}_{n+1} &\approx i \frac{\Delta t}{2(1 + \xi_1^2)} (\xi_1 + a\xi_2^2/\xi_1 + b\xi_3^2/\xi_1) (\widehat{u}_{n+1, r} - \widehat{u}_{n+1}) \\ &\quad + i\xi_1 \frac{\Delta t}{2(1 + \xi_1^2)} \left(\frac{\widehat{u_{n+1, r}^{p+1}}}{p+1} - \frac{\widehat{u_{n+1}^{p+1}}}{p+1} \right), \end{aligned}$$

it follows in the case where $p \in \mathbb{N}^*$ that,

$$\begin{aligned} \widehat{u}_{n+1, r+1} - \widehat{u}_{n+1} &\approx i \frac{\Delta t}{2(1 + \xi_1^2)} (\xi_1 + a\xi_2^2/\xi_1 + b\xi_3^2/\xi_1) (\widehat{u}_{n+1, r} - \widehat{u}_{n+1}) \\ &\quad + i\xi_1 \frac{\Delta t}{2(1 + \xi_1^2)(p+1)} \sum_{j=0}^p (\widehat{u_{n+1, r} - u_{n+1}}) u_{n+1, r}^j u_{n+1}^{p-j}, \end{aligned}$$

and a linearization (near u_n) in the right-hand side of this relation leads to the approximation:

$$\widehat{u}_{n+1, r+1} - \widehat{u}_{n+1} \approx i \frac{\Delta t}{2(1 + \xi_1^2)} (\xi_1 + a\xi_2^2/\xi_1 + b\xi_3^2/\xi_1) (\widehat{u}_{n+1, r} - \widehat{u}_{n+1}) + i\xi_1 \frac{\Delta t}{2(1 + \xi_1^2)} (\widehat{u_{n+1, r} - u_{n+1}}) u_n^p.$$

Then, since $\xi_1/(1 + \xi_1^2) \leq 1/2$, $\xi_2 \leq \pi/\Delta y$, $\xi_3 \leq \pi/\Delta z$, it follows that for $k \neq 0$, and making use of the Parseval formula,

$$\|u_{n+1, r+1} - u_{n+1}\|_{L^2(\Omega)} \lesssim \frac{\Delta t}{4} \left(1 + (K/\Delta y)^2 + (K/\Delta z)^2 + \|u_n\|_{L^\infty(\Omega)}^p \right) \|u_{n+1, r} - u_{n+1}\|_{L^2(\Omega)}.$$

2 Long time behavior for localized initial data

We are interested here in numerical simulations concerning the Cauchy problem. In a general way, two sets of parameters will be considered for these simulations based on the algorithm described previously. The first set is made up of the parameters $a, b = \pm 1$, $p \geq 1$, that intervene in (3), and the second one concerns the parameters $K, L, M, \Delta t, N_x, N_y, N_z$ used in the algorithm. Here, we focus on integer values of p , the numerical scheme proposed here works also for real and very large non-linearities.

To study the behavior in long time of the discrete solution of (3), associated with a localized initial datum, two phenomena will systematically be inspected: the dispersion (context where the L^∞ -norm of the solution decreases) and the solitonic behavior (phenomenon where the L^∞ -norm of the solution is constant). Let us remind that no theoretical result concerning the Cauchy problem based on (3) is established. The two-dimensional case of the numerical investigation regarding (3) is treated in [9].

Our numerical inspections will be based on the choice: for $\alpha, s \in \mathbb{R}_+^*$,

$$u_0(x, y, z) = \alpha(1 - 2sx^2) e^{-s(x^2+y^2+z^2)}, \quad (10)$$

and on various considerations of parameters mentioned above. Let us indicate that the choices of values of K will be such that u_0 satisfies (5) numerically.

In the presentation of our results, we distinguish the case $p = 1$ and the generalized case where $p > 1$.

2.1 Non-generalized case: $p = 1$

In this subsection, we describe the results obtained from numerical simulations by fixing $p = 1$. In each of the contexts where $a = \pm 1$ with $b = \pm 1$, we perform experiments by setting here: $s = 1$, $K = 50$, $L = M = 4$, $N_y = N_z = 16$. We already mention that for all our experiments, here and in the next sections, the step Δt will always be chosen in accordance with (9). We observe the same evolutions of these norms when $a = -1$, $b = 1$ as well as when $a = 1$, $b = -1$. This was foreseeable according to the symmetry of u_0 and to the one of (3) related to the y and z -directions. In this order of ideas, we restrict in this section the presentation of our results to the contexts where $ab = 1$, and $a = -1$, $b = 1$.

The results represented in Figure 1 concern the evolutions with respect to time of the l^∞ and h^1 -norms of the discrete solution obtained by considering $N_x = 256$, $\Delta t = 10^{-3}$, $\alpha = 5$.

Figure 1: Evolutions of the h^1 -norm (---) and the l^∞ -norm (—) with respect to time, for $p = 1$, $\alpha = 5$, $s = 1$, $K = 50$, $L = M = 4$, $N_x = 256$, $N_y = N_z = 16$, $\Delta t = 10^{-3}$.

Let us notice that for these choices of α , the results obtained from simulations with other values of parameters, namely with $K = 32$, $L = M = 6, 12$, $N_x = 128$, $N_y = N_z = 32, 64$, do not qualitatively differ from those represented in this section. We observe that the h^1 -norm is conserved by the flow of (3), and the l^∞ -norm decreases with time. Put another words, the dispersive effect prevails over the non-linearity. The evolutions of the norms in the different contexts where $ab = \pm 1$ look similar.

Figure 2 presents the evolutions of the l^∞ and h^1 -norms of the discrete solution when a larger amplitude of the initial datum is considered. Here $\alpha = 50$, $N_x = 512$ and $\Delta t = 10^{-4}$.

In each of the contexts where $a = b = 1$, $ab = -1$, we observe, as with $\alpha = 5$, that the dispersive effect prevails over the non-linearity (similar to Figure 1). But for $a = b = -1$, the discrete solution, associated with the initial datum of larger amplitude, has a tendency to blow up at the beginning of the evolution and after that, the dispersive effect prevents the solution from blowing up. The fact that the non-linearity and the dispersive effect are neutralized, and that the L^∞ -norm is stabilized, is called the solitonic behavior. This means that the velocity of the limit profile has a periodic-like behavior in time. We mention that when we take larger values of L, M, N_y, N_z (e.g. $L = M = 6$, $N_y = N_z = 32$), we do not obtain, from the simulations, results that are qualitatively different from those presented here.

Figure 2: At left, evolutions of the h^1 -norm (---) and the l^∞ -norm (—) with respect to time. At center, the projection on the x -axis of the localized initial datum. At right, the projection at time $T = 10$. Here $p = 1, a = b = -1, \alpha = 50, s = 1, K = 50, L = M = 4, N_x = 512, N_y = N_z = 16, \Delta t = 10^{-4}$.

2.2 Generalized case: $p > 1$

In this subsection, we are concerned with numerical experiments when $p = 2, 3$.

Let us fix in this part $p = 2$. The experiments associated with Figure 3 is performed by setting: $s = 1, K = 50, L = M = 4, N_x = 512, N_y = N_z = 16$ and $\Delta t = 10^{-4}$. In Figure 3, we represent the evolutions with respect to time of the l^∞ and h^1 -norms of the discrete solution obtained by considering $\alpha = 10$.

Figure 3: Evolutions of the h^1 -norm (---) and the l^∞ -norm (—) with respect to time, for $p = 2, \alpha = 10, s = 1, K = 50, L = M = 4, N_x = 512, N_y = N_z = 16, \Delta t = 10^{-4}$.

It appears that the l^∞ -norm has a tendency to blow up and then the evolution of the norm is stabilized, the solitonic behavior is observed. As for the case $p = 1$, we observe that the dispersive effect prevails over the non-linearity in the contexts where $a = b = 1, ab = -1$.

The numerical results known from [10] concerning the equation (1), for $p = 2$, in the context where $a = b = -1$, report that the non-linearity is stronger than the dispersive effect and the solution blows up. The behavior of the solution is here completely different, the solitonic behavior is observed. When $a = b = 1$ and $ab = -1$, the dispersion is also observed for solutions of (1).

The observations are confirmed when we use larger values of N_x, N_y, N_z (e.g. with $N_x = 1024, N_y = N_z = 32$).

We can already predict that, since the non-linearity was persistent with $p = 2$, the solitonic behavior

will be at least observed in the case $p = 3$ because of a stronger non-linearity.

Let us now fix $p = 3$. In our first experiments, associated with Figure 4, we considered $s = 1$, $L = M = 6$, $N_x = 512$, $N_y = N_z = 32$ and $\Delta t = 10^{-4}$. Figure 4 shows the evolutions (with respect to time) of the l^∞ and h^1 -norms of the discrete solution obtained when $K = 50$, $\alpha = 5$.

Figure 4: Evolutions of the h^1 -norm (---) and the l^∞ -norm (—) with respect to time, for $p = 3$, $\alpha = 5$, $s = 1$, $K = 50$, $L = M = 6$, $N_x = 512$, $N_y = N_z = 32$, $\Delta t = 10^{-4}$.

These experiments confirm that the non-linearity effect is effectively as strong as the dispersive effect. When $a = b = -1$, the solution has a tendency to blow-up at the beginning and then is stabilized. In the other hand, the solution slowly decreases, then the L^∞ -norm is also stabilized (in Figure 4, l^∞ -norm remains close to 2 at left and right).

Let us now summarize our results. The effect of dispersion are less important for two negative transverse directions than for two positive or opposite transverse directions. Indeed, the solitonic behavior of the discrete solution, in the context where $a = b = -1$, is observed when $p \geq 1$, whereas the one involved in each of the contexts where $a = b = 1$, and $ab = -1$ when $p = 3$. Moreover, comparing to the result observed for the solutions of (1), instead of the blow-up in finite time [10], the solitonic behavior takes place.

Let us notice that the solitonic behavior observed in this paper is not in contradiction with the non-existence results of solitary waves in [6]. In every cases, we obtain a destabilized solitonic behavior in the sense that the amplitude of the solution varies not much but the solution do not remain close to the initial datum. In other words, there exists $T > 0$ such that for $t \geq T$

$$\|u(T) - u(t)\|_\infty \leq \epsilon, \text{ and } \|u_0(\cdot - ct) - u(t)\|_\infty \geq C.$$

3 Transverse instabilities in the y and z -directions

The generalized equation (3) admits as solution the line-soliton

$$\Phi_c(x, t) = \left(\frac{(p+1)(p+2)}{2} c \right)^{1/p} \text{sech}^{2/p} \left(\frac{p}{2} (x - ct) \right),$$

which is a solution of the generalized BBM equation. This represents a solitary wave, moving from left to right in the x -direction, at velocity c , without deformation. In this section, we study the evolution in time of this line-soliton perturbed in an infinitesimal way in the two transverse y and z -directions. We consider then the Cauchy problem by defining the initial datum u_0 as follows,

$$u_0(x, y, z) := \Phi_{c(y,z)}(x, 0),$$

where $c(y, z) := c(1 + \varepsilon \cos(2\pi y/\lambda_y + 2\pi z/\lambda_z))$, with $\varepsilon > 0$ a fixed small value; this perturbed velocity is not uniform in the transverse directions, λ_y and λ_z are the wavelengths.

3.1 Non-generalized case: $p = 1$

We fix $p = 1$ in this subsection. In addition to the two previous sets of parameters, our numerical experiments will be performed with respect to diverse considerations of c , λ_y and λ_z .

In each of the contexts where $ab = \pm 1$, we perform simulations by fixing $K = 50$, $L = M = 4$, $N_x = 256$, $N_y = N_z = 16$, $\Delta t = 10^{-3}$, $\varepsilon = 10^{-2}$. Results are not influenced by the choice of smaller steps, and of smaller values of ε .

We start by considering the context where $a = b = -1$. In Figure 5, we represent the evolutions of the l^∞ and h^1 -norms of the discrete solution obtained respectively with $\lambda_y = \lambda_z = 50$, for $c = 4$.

Figure 5: At left, evolutions of the h^1 -norm (---) and the l^∞ -norm (—) with respect to time, for $p = 1, a = b = -1, c = 4, K = 50, L = M = 4, N_x = 256, N_y = N_z = 16, \Delta t = 10^{-3}$. Here, $\lambda_y = \lambda_z = 50$ and $\varepsilon = 10^{-2}$. At center, the projection on the x -axis of the initial line-soliton. At right, the projection at time $T = 40$.

Similar results derive also from simulations by using larger values for K, L, M, N_x, N_y, N_z , and by considering distinct values for λ_y and λ_z .

Let us now consider the contexts where $ab = -1$, by using again $c = 4$ in the experiments. Figure 6 shows the results obtained respectively for $a = -1, b = 1$, when $\lambda_y = 0.01, \lambda_z = 50$.

Figure 6: At left, evolutions of the h^1 -norm (---) and the l^∞ -norm (—) with respect to time. At center, the projection on the x -axis of the initial line-soliton. At right, the projection at time $T = 40$. Here $p = 1, a = -1, b = 1, c = 4, K = 50, L = M = 4, N_x = 256, N_y = N_z = 16, \Delta t = 10^{-3}$, $\lambda_y = 0.01, \lambda_z = 50$ and $\varepsilon = 10^{-2}$.

We observe from simulations the same evolutions of the norms in the contexts where $ab = \pm 1$. The profile of the discrete solution is slightly perturbed during time, and the amplitude of wave remains close to the one of the initial datum. Some dispersive tail appears and the number of waves is increasing with respect to time.

3.2 Generalized case: $p > 1$

We aim here to study the transverse instabilities in the case where $p = 2$.

Our experiments are performed in each of the contexts where $ab = \pm 1$, by fixing $K = 50$, $L = M = 4$, $N_x = 256$, $N_y = N_z = 16$ and $\Delta t = 5 \times 10^{-4}$, $\varepsilon = 10^{-2}$. Figures 7 and 8 present, for $c = 4$, the evolutions of the h^1 and l^∞ -norms of the discrete solution obtained respectively with $\lambda_y = 0.01, 50, \lambda_z = 50$.

Figure 7: Evolutions of the h^1 -norm (---) and the l^∞ -norm (—) with respect to time for $p = 2, a = b = -1, ab = -1, c = 4, K = 50, L = M = 4, N_x = 256, N_y = N_z = 16, \Delta t = 5 \times 10^{-4}, \lambda_y = \lambda_z = 50$ and $\varepsilon = 10^{-2}$.

Figure 8: Evolutions of the h^1 -norm (---) and the l^∞ -norm (—) with respect to time. Here $p = 2, a = b = -1, ab = -1, c = 4, K = 50, L = M = 4, N_x = 256, N_y = N_z = 16, \Delta t = 5 \times 10^{-4}, \lambda_y = 0.01, \lambda_z = 50$ and $\varepsilon = 10^{-2}$.

In the contexts $a = b = -1$ and $ab = -1$, the solitonic behavior is observed. When $a = b = 1$, we obtain similar results as in Figure 5.

We can inspect the influence of the velocity. Due to the non-homogeneous dependence of the velocity, it is difficult to determine a precise critical value. Independently of the small values of ε , we notice that

the larger is the velocity, the smaller is this critical value. For $c > 0$, there exists a critical transverse wavelength $\lambda_c^1 = \lambda^1/c$ such that if λ_y and λ_z is larger than λ_c^1 , the perturbed line-soliton is unstable.

We extend our experiments to very large wavelengths. We can notice that the formal limit of the perturbed line-soliton, when λ_y and λ_z tend to infinity, gives $\Phi_{c(1+\varepsilon)}$, which does not depend on the transverse variables. In particular, the solution of (3) with $\Phi_{c(1+\varepsilon)}$ as initial datum is stable [29].

We thus deduce, in the context where $a = b = -1$, that there exists another critical transverse wavelength λ_c^2 such that if λ_y or $\lambda_z > \lambda_c^2$, the perturbed line-soliton is no longer unstable (similar to Figure 5).

The results are confirmed by the case $p = 3$. Even in the context $a = b = -1$ and $ab = -1$, the discrete solution is unstable.

Figure 9: Evolutions of the h^1 -norm (---) and the l^∞ -norm (—) with respect to time. Here $p = 3, c = 4, K = 50, L = M = 6, N_x = 512, N_y = N_z = 32, \Delta t = 10^{-4}, \lambda_y = \lambda_z = 50$ and $\varepsilon = 10^{-2}$.

Let us now summarize the numerical observations of this section. When $p = 1$ and $a = b = -1, ab = -1$ or $p \geq 1, a = b = 1$, the profile of the discrete solution remains close to the initial datum and some dispersive tail appears and increases with respect to time. This does not allow to conclude on the stability of the line-soliton, the range of perturbations being not sufficiently exhaustive.

The experiments for $p = 2, 3$ show that when the line-soliton is perturbed in the two transverse directions by neither very small nor very large wavelengths, the associated discrete solution is unstable in the sense that the solution does not remain close to the initial datum but behaves like a soliton. Concerning the KP equations (1), the solution is also unstable, and moreover the solution blows up in finite time [10].

These observations lead us to formulate the following conjecture.

Conjecture 3.1

For $\varepsilon > 0$ sufficiently small, let u_0 be the perturbed line-soliton of velocity $c(y, z) := c(1 + \varepsilon \cos(2\pi y/\lambda_y + 2\pi z/\lambda_z))$, where $\lambda_y, \lambda_z > 0$. Let $p \geq 2$, and $a = b = -1$ or $ab = -1$. There exist two critical transverse wavelengths $0 < \lambda_c^1 \ll \lambda_c^2$, depending only on c , such that the solution u of (3), with u_0 as initial datum, is unstable under the flow of (3) if $\lambda_c^1 < \lambda_y < \lambda_c^2$ respectively or $\lambda_c^1 < \lambda_z < \lambda_c^2$.

4 Transverse instability in the z -direction

We are concerned in this section with the perturbation of the profile of the Zaitsev traveling waves [31]. The function

$$\psi_c(x, y) = 12\alpha^2 c \frac{1 - \beta \cosh(\alpha x) \cos(\delta y)}{(\cosh(\alpha x) - \beta \cos(\delta y))^2},$$

with

$$\beta = \sqrt{1 - \frac{3c\alpha^4}{\delta^2}}, 3c\alpha^4 < \delta^2, \alpha^2 + \frac{\delta^2}{c\alpha^2} = 1, p = 1, a = -1$$

which is localized in the x -direction and periodic in the y -direction, represents such a profile.

We want to study the evolution, subject to (3), of the Zaitsev wave when it is perturbed in the second transverse direction. We then consider

$$u_0(x, y, z) := \psi_{c(z)}(x, y, 0),$$

as the initial datum associated with (3). The velocity is here slightly perturbed in the z -direction; namely, $c(z) := c(1 + \varepsilon \cos(2\pi z/\lambda_z))$, with $\varepsilon > 0$ small and $\lambda_z > 0$ a wavelength.

Our numerical simulations will be performed in each of the contexts where $b = \pm 1$. In what follows, we consider $K = 50$, $L = 12$, $M = 4$, $N_x = 256$, $N_y = 32$, $N_z = 16$, $\Delta t = 10^{-3}$, $\varepsilon = 10^{-2}$. The value of L is larger than in the previous sections in such a way that the present initial datum u_0 also satisfies (5) numerically.

The results represented in Figure 10 concern the context where $b = -1$, and show for $c = 4$ the evolutions of the h^1 and l^∞ -norms of the discrete solution obtained with $\lambda_z = 50$. Similar results derive from simulations, even by using larger values of K, L, N_x, N_y and smaller values of ε .

Figure 10: At left, evolutions of the h^1 -norm (---) and the l^∞ -norm (—) with respect to time. At center, the projection on the x -axis of the initial Zaitsev soliton. At right, the projection at time $T = 40$. Here $b = -1, c = 4, K = 32, L = 12, M = 4, N_x = 256, N_y = 32, N_z = 16, \Delta t = 10^{-3}, \lambda_z = 50$ and $\varepsilon = 10^{-2}$.

We notice that there exists a critical transverse wavelength $\lambda_c^1 = \lambda^1/c$, such that if $\lambda_z > \lambda_c^1$, the solution has a tendency to blow up and then is stabilized. Moreover, there exists another critical transverse wavelength λ_c^2 such that if $\lambda_z > \lambda_c^2$, the perturbed Zaitsev wave is no more unstable.

In the last context where $b = 1$, the results of Figure 11 are obtained from experiments performed in this context by setting $c = 4$. The solution is also unstable, but in this case, no solitonic behavior is observed.

Figure 11: At left, evolutions of the h^1 -norm (---) and the l^∞ -norm (—) with respect to time, for $b = 1, c = 4, K = 50, L = 12, M = 4, N_x = 256, N_y = 32, N_z = 16, \Delta t = 10^{-3}$. Here, $\lambda_z = 50$ and $\varepsilon = 10^{-2}$. At center, the projection on the x -axis of the initial Zaitsev soliton. At right, the projection at time $T = 40$.

It follows that the wavelength λ_z characterizes the instability of the Zaitsev wave by transverse perturbations in the z -direction. More precisely, when $b = \pm 1$, there exist two critical transverse wavelengths $0 < \lambda_c^1 \ll \lambda_c^2$, depending only on c , such that the corresponding discrete solution is unstable if $\lambda_c^1 < \lambda_z < \lambda_c^2$.

Then, we can formulate the following conjecture.

Conjecture 4.1

For $\varepsilon > 0$ sufficiently small, let u_0 be the perturbed Zaitsev wave of velocity $c(z) := c(1 + \varepsilon \cos(2\pi z/\lambda_z))$, where $\lambda_z > 0$. Let $p = 1$, and $a = -1$. There exist two critical transverse wavelengths $0 < \lambda_c^1 \ll \lambda_c^2$, depending only on c , such that the solution of (3), with u_0 as initial datum, is unstable if $\lambda_c^1 < \lambda_z < \lambda_c^2$.
