ADDITIVE DECOMPOSABILITY OF FUNCTIONS OVER
ABELIAN GROUPS

MIGUEL COUCEIRO, ERKKO LEHTONEN, AND TAMÁS WALDHAUSER

ABSTRACT. Abelian groups are classified by the existence of certain additive decompositions of group-valued functions of several variables with arity gap 2.

1. Introduction

The arity gap of a function \( f : A^n \to B \) is defined as the minimum decrease in the number of essential variables when essential variables of \( f \) are identified. Up to the authors’ knowledge, this notion first appeared in the 1963 paper by Salomaa [21], where it was shown that the arity gap of every Boolean function is at most 2. Willard [28] generalized this by showing that a function \( f : A^n \to B \) defined on a finite set \( A \) and depending on all of its variables has arity gap at most 2 whenever \( n > \max(|A|, 3) \); moreover, the arity gap of such a function equals 2 if and only if \( f \) is determined by oddsupp (see Section 2 for definitions). Several papers on the topic have appeared ever since, e.g., [5, 7, 8, 9, 23, 24]. A complete classification of functions according to their arity gap was presented in [6].

In a previous paper of the authors’ [8], unique additive decompositions of functions \( f : A^n \to B \) were presented, assuming that \( B \) has a group structure and the arity gap of \( f \) is at least 3. Similar decompositions were also proposed by Shtrakov and Koppitz [24]. Further decompositions were also established in [8] for functions whose arity gap is 2, but in this case the codomain \( B \) was required to be a Boolean group. In the current paper, we study similar additive decompositions of functions \( f : A^n \to B \) into sums of functions with a smaller number of essential variables, assuming that \( B \) is an abelian group. We show that such a decomposition exists for all functions \( f : A^n \to B \) determined by oddsupp if and only if \( A \) is finite and the exponent of \( B \) is a power of 2.

2. Preliminaries

2.1. Functions, essential variables, the arity gap. Throughout this paper, let \( A \) and \( B \) be arbitrary sets with at least two elements. A partial function (of several variables) from \( A \) to \( B \) is a mapping \( f : S \to B \), where \( S \subseteq A^n \) for some integer \( n \geq 1 \), called the arity of \( f \). If \( S = A^n \), then we speak of (total) functions (of several variables). Functions of several variables from \( A \) to \( A \) are referred to as operations on \( A \).

For an integer \( n \geq 1 \), let \([n] := \{1, \ldots, n\}\). Let \( f : S \to B \) (\( S \subseteq A^n \)) be an \( n \)-ary partial function and let \( i \in [n] \). We say that the \( i \)-th variable is essential in \( f \) (or \( f \) depends on \( x_i \)), if there exist tuples

\((a_1, \ldots, a_{i-1}, a_i, a_{i+1}, \ldots, a_n), (a_1, \ldots, a_{i-1}, a'_i, a_{i+1}, \ldots, a_n) \in S\)
such that
\[ f(a_1, \ldots, a_{i-1}, a_i, a_{i+1}, \ldots, a_n) \neq f(a_1, \ldots, a_{i-1}, a'_i, a_{i+1}, \ldots, a_n). \]

Variables that are not essential are called inessential. The cardinality of the set \( \text{Ess } f := \{ i \in [n] : x_i \text{ is essential in } f \} \) is called the essential arity of \( f \) and is denoted by \( \text{ess } f \).

Let \( f : A^n \to B, g : A^m \to B \). We say that \( g \) is a simple minor of \( f \), if there is a map \( \sigma : [n] \to [m] \) such that \( g(x_1, \ldots, x_m) = f(x_{\sigma(1)}, \ldots, x_{\sigma(n)}) \). We say that \( f \) and \( g \) are equivalent if each one is a simple minor of the other.

For \( i, j \in [n], i \neq j \), define the identification minor of \( f : A^n \to B \) obtained by identifying the \( i \)-th and the \( j \)-th variable as the simple minor \( f_{i \leftarrow j} : A^n \to B \) of \( f \) corresponding to the map \( \sigma : [n] \to [n], i \mapsto j, \ell \mapsto \ell \) for \( \ell \neq i \), i.e., \( f_{i \leftarrow j} \) is given by the rule
\[ f_{i \leftarrow j}(x_1, \ldots, x_n) := f(x_1, \ldots, x_{i-1}, x_j, x_{i+1}, \ldots, x_n). \]

Observe that a function \( g \) is a simple minor of \( f \), if \( g \) can be obtained from \( f \) by permutation of variables, addition and deletion of inessential variables and identification of variables. Similarly, two functions are equivalent, if one can be obtained from the other by permutation of variables and addition of inessential variables.

The arity gap of \( f \) is defined as
\[ \text{gap } f := \min_{i,j \in \text{Ess } f, i \neq j} (\text{ess } f - \text{ess } f_{i \leftarrow j}). \]

Note that the definition of arity gap makes reference to essential variables only. Hence, in order to determine the arity gap of a function \( f \), we may consider instead an equivalent function \( f' \) that is obtained from \( f \) by deleting its inessential variables. It is easy to see that in this case \( \text{gap } f = \text{gap } f' \). Therefore, we may assume without loss of generality that every function the arity gap of which we may consider depends on all of its variables.

For general background and studies on the dependence of functions on their variables, see, e.g., [3, 4, 11, 12, 13, 21, 25, 27, 29]. For the simple minor relation and its variants, see, e.g., [2, 10, 14, 17, 18, 19, 20, 26, 30]. The notion of arity gap was considered in [3, 6, 7, 8, 9, 21, 23, 24, 28], and a general classification of functions according to their arity gap was established in [5], given in terms of the notions of quasi-arity and determination by oddsupp. The following explicit complete classification of Boolean functions was established in [5].

**Theorem 2.1.** Let \( f : \{0,1\}^n \to \{0,1\} \) be a Boolean function with at least two essential variables. Then \( \text{gap } f = 2 \) if and only if \( f \) is equivalent to one of the following polynomial functions over \( \text{GF}(2) \):

1. \( x_1 + x_2 + \cdots + x_m + c \) for some \( m \geq 2 \),
2. \( x_1x_2 + x_1 + c \),
3. \( x_1x_2 + x_1x_3 + x_2x_3 + c \),
4. \( x_1x_2 + x_1x_3 + x_2x_3 + x_1 + x_2 + c \),

where \( c \in \{0,1\} \). Otherwise \( \text{gap } f = 1 \).

**2.2. Functions determined by oddsupp.** We will denote tuples by boldface letters and their components by the corresponding italic letters with subscripts, e.g., \( x = (x_1, \ldots, x_n) \in A^n \). For \( I \subseteq [n] \) and \( x \in A^n \), let \( x|_I \in A^I \) stand for the tuple
that is obtained from $x$ by deleting the $i$-th component of $x$ for every $i \notin I$. More precisely, if $I = \{i_1, \ldots, i_k\}$ and $i_1 < \cdots < i_k$, then $x|_I = (x_{i_1}, \ldots, x_{i_k})$.

Berman and Kisielewicz [1] introduced the following notion of a function’s being determined by oddsupp. Denote by $\text{oddsupp}(A)$ the power set of $A$, and define the function oddsupp: $\bigcup_{n \geq 1} A^n \rightarrow \mathcal{P}(A)$ by
\[
\text{oddsupp}(a_1, \ldots, a_n) := \{a \in A : \{j \in [n] : a_j = a\} \text{ is odd}\}.
\]
For $\varphi: \mathcal{P}(A) \rightarrow B$, let $\#_{\varphi}: \bigcup_{n \geq 1} A^n \rightarrow B$ be defined by $\#_{\varphi}(x) = \varphi(\text{oddsupp}(x))$.

A function $f: S \rightarrow B$ is determined by oddsupp if $f(x)$ depends only on oddsupp($x$), i.e., if there exists $\varphi: \mathcal{P}(A) \rightarrow B$ such that $\#_{\varphi}|_S = f$. When there is no risk of ambiguity, we will simply write $\#_{\varphi}$ instead of $\#_{\varphi}|_S$. Clearly, if $S = A^n$, then the restriction of $\varphi$ to
\[
\mathcal{P}'_n(A) = \{S \in \mathcal{P}(A) : |S| \in \{n, n-2, \ldots\}\}
\]
uniquely determines $f$ and vice versa. Thus, for finite sets $A$ and $B$, the number of functions $f: A^n \rightarrow B$ that are determined by oddsupp is $|B|^{|\mathcal{P}(A)|}$. The following facts are straightforward to verify.

**Fact 2.2.** The Boolean functions determined by oddsupp are exactly the affine functions (also known as linear functions in the theory of Boolean functions).

**Fact 2.3.** A function $f: A^n \rightarrow B$ is determined by oddsupp if and only if $f$ is totally symmetric and $f_{2-1}$ does not depend on $x_1$.

**Fact 2.4.** If $(B; +)$ is an abelian group, then $\#_{\varphi_1 + \varphi_2} = \#_{\varphi_1} + \#_{\varphi_2}$ holds for all maps $\varphi_1, \varphi_2: \mathcal{P}(A) \rightarrow B$.

It was shown by Willard [28] that if the essential arity of a function $f: A^n \rightarrow B$ is sufficiently large, then $\text{gap } f \leq 2$, and he also classified such functions according to their arity gap.

**Theorem 2.5 (Willard [28]).** Let $A$ be a finite set and $B$ be an arbitrary set, and assume that $f: A^n \rightarrow B$ depends on all of its variables and $n > \max(|A|, 3)$. If $f$ is determined by oddsupp then $\text{gap } f = 2$. Otherwise $\text{gap } f = 1$.

If $B$ is a Boolean group (i.e., an abelian group of exponent 2), then functions $f$ with $\text{gap } f \geq 2$ can be characterized by the existence of certain additive decompositions. Here we present one of the main results of [8] in the case $n > \max(|A|, 3)$. In this case, by Theorem 2.5 $\text{gap } f \geq 2$ if and only if $f$ is determined by oddsupp.

**Theorem 2.6 ([8]).** Let $(B; +)$ be a Boolean group, and let $f: A^n \rightarrow B$ be determined by oddsupp. Then there exists a map $\varphi: \mathcal{P}'_n(A) \rightarrow B$ such that
\[
f(x) = \sum_{i=1}^{\lfloor \frac{n}{2} \rfloor} \sum_{|I| = n-2i} \#_{\varphi}(x|_I).
\]

Equation (1) expresses the fact that every function $f: A^n \rightarrow B$ with large enough essential arity and $\text{gap } f = 2$ is decomposable into a sum of essentially at most $(n-2)$-ary functions. This fact is the starting point of the current paper. We will prove in Section 3 that such decompositions exist not only when $B$ is a Boolean group, but also whenever $B$ is a group whose exponent is a power of 2. In fact, we will show that in this case there is a decomposition into functions with bounded
essential arity, where the bound does not depend on $n$. We will also see that if the exponent of $B$ is not a power of 2, then such a decomposition does not always exist, not even a decomposition into $(n - 1)$-ary functions. In Section 3, we focus on Boolean groups $B$, and we provide a concrete decomposition of a very special symmetric form, which is also unique.

Any set $B$ can be embedded into a Boolean group, e.g., into $\mathcal{P}(B)$ with the symmetric difference operation. Then we can regard any function $f: A^n \to B$ as a function from $A^n$ to $\mathcal{P}(B)$, and we can apply the results of Section 3 to this function. We illustrate this for the case $A = B = \mathbb{Z}_3$ in Section 4. Here we obtain decompositions involving a strange mixture of the field operations on $\mathbb{Z}_3$ and the symmetric difference operation, but we will see that they can be always computed within $B$, without the need of working in the extension $\mathcal{P}(B)$.

2.3. Binomial coefficients. We shall make use of the following combinatorial results.

**Theorem 2.7** (Shattuck, Waldhauser [22]). For all nonnegative integers $m$, $t$ with $0 \leq t \leq \frac{m}{2} - 1$, the following identity holds:

$$\sum_{i=t+1}^{\lfloor m/t \rfloor} \binom{m}{2i} \binom{i-1}{t} = 2^{m-2t-1} \sum_{k=0}^{t} \binom{m - 3 - t - 2k}{t - 2k} + (-1)^{t+1}. $$

**Theorem 2.8.** For all nonnegative integers $m$, $t$ with $0 \leq t \leq \frac{m-1}{2}$ the following identity holds:

$$\sum_{k=t+1}^{\lfloor (m+1)/t \rfloor} \binom{m}{2k-1} \binom{2k-1}{2t} = \binom{m}{2t} 2^{m-2t-1}. $$

**Proof.** Both sides of the identity count the number of pairs $(A,B)$, where $A \subseteq B \subseteq [m]$, $|A| = 2t$, and $|B|$ is odd. \qed

3. The general case

Throughout this section, unless mentioned otherwise, $A$ is a finite set with a distinguished element $0_A$ and $(B; +)$ is an arbitrary, possibly infinite abelian group with neutral element $0_B$. With no risk of ambiguity, we will omit the subscripts and will denote both $0_A$ and $0_B$ by 0. Recall that the order of $b \in B$, denoted by $\text{ord}(b)$, is the smallest positive integer $n$ such that $nb = b + \cdots + b = 0$. If there is no such positive integer, then $\text{ord}(b) = \infty$. If the orders of all elements of $B$ have a finite common upper bound, then the exponent of $B$, denoted by $\exp(B)$, is the least common upper bound (equivalently, the least common multiple) of these orders. Otherwise let $\exp(B) = \infty$. Note that a Boolean group is a group of exponent 2.

We say that a function $f: A^n \to B$ is $k$-decomposable if it admits an additive decomposition $f = f_1 + \cdots + f_s$, where the essential arity of each $f_i: A^n \to B$ is at most $k$. Moreover, we say that $f$ is decomposable if it is $(n - 1)$-decomposable.

According to Fact 2.2, every Boolean function determined by oddsupp is 1-decomposable, while the functions described in Theorem 2.6 are $(n - 2)$-decomposable. Our goal in this section is to extend these results by characterizing those abelian groups $B$ which have the property that every function $f: A^n \to B$ determined by oddsupp is decomposable. As we will see, this is the case if and only if
exp(B) is a power of 2. Moreover, we will determine, for each such abelian group B, the smallest number k such that every function \( f: A^n \to B \) determined by oddsupp is k-decomposable.

The Taylor formula developed for finite functions by Gilezan [16] provides a tool to test decomposability of functions. Although in [16] the codomain B was assumed to be a ring, only multiplication by 0 and 1 was used in the Taylor formula; hence it is valid for abelian groups as well. For self-containedness, we present here the formula with a proof (see Proposition 3.2).

For a given \( x \in A^n \) and \( i \in [n], a \in A \), let \( x^i_a \) denote the n-tuple that is obtained from \( x \) by replacing its \( i \)-th component by \( a \). More generally, for \( I \subseteq [n] \) and \( a \in A^n \), let \( x^I_a \) denote the n-tuple that is obtained from \( x \) by replacing its \( i \)-th component by \( a_i \) for every \( i \in I \). (Observe that the components \( a_i \) of \( a \) with \( i \notin I \) are irrelevant in determining \( x^I_a \).)

For any \( a \in A \) and \( i \in [n] \) we define the partial derivative of \( f: A^n \to B \) with respect to its \( i \)-th variable with parameter \( a \) as the function \( \Delta_i^a f: A^n \to B \) given by

\[
\Delta_i^a f(x) = f(x^i_a) - f(x).
\]

Note that for each parameter \( a \in A \) we have a different partial derivative of \( f \) with respect to its \( i \)-th variable. We need the parameter \( a \) because \( A \) is just a set without any structure; hence we cannot define differences like \( f(x + h) - f(x) \). It is easy to verify that the \( i \)-th variable of \( f \) is inessential if and only if \( \Delta_i^a f \) is identically 0 for some \( a \in A \) (equivalently, for all \( a \in A \)).

Clearly, the partial derivatives are additive, i.e., \( \Delta_i^a (f + g) = \Delta_i^a f + \Delta_i^a g \). Moreover, differentiations with respect to different variables commute with each other:

\[
(2) \quad \Delta_i^a \Delta_j^b f(x) = \Delta_j^b \Delta_i^a f(x) = f(x^i_a b_j) - f(x^i_a) - f(x^b_j) + f(x)
\]

for all \( a, b \in A, i \neq j \in [n] \). (Here \( x^i_a b_j \) is a shorthand notation for \( (x^i_a)_j = (x^i_j)_a \).) This property allows us to define higher-order derivatives: for \( I = \{i_1, \ldots, i_k\} \subseteq [n] \) and \( a \in A^n \) let \( \Delta_I^a f = \Delta_i^{a_{i_1}} \cdots \Delta_i^{a_{i_k}} f \). (Again, the components \( a_i \) (\( i \notin I \)) are irrelevant.) The following proposition generalizes formula (2) above.

**Proposition 3.1.** For any function \( f: A^n \to B, I \subseteq [n] \) and \( a \in A^n \), we have

\[
\Delta_I^a f(x) = \sum_{J \subseteq I} (-1)^{|I \setminus J|} f(x_J^a).
\]

**Proof.** Easy induction on \( |I| \). (For \( |I| = 2 \), the identity is just (2).) \( \square \)

Now we are ready to state and prove the Taylor formula for functions \( f: A^n \to B \), which is essentially the same as Theorem 2 and Theorem 3 in [16]. (Let us note that in the following considerations any fixed n-tuple \( a \in A^n \) could be used instead of \( 0 \).)

**Proposition 3.2.** Any function \( f: A^n \to B \) can be expressed as a sum of some of its partial derivatives at \( 0 \):

\[
(3) \quad f(x) = \sum_{I \subseteq [n]} \Delta_I^a f(0).
\]

**Proof.** Using Proposition 3.1 we can compute the right-hand side as follows:

\[
\sum_{I \subseteq [n]} \Delta_I^a f(0) = \sum_{I \subseteq [n]} \sum_{J \subseteq I} (-1)^{|I \setminus J|} f(0_J^a).
\]
Observe that $K := I \setminus J$ can be any subset of $[n] \setminus J$. Hence
\[
\sum_{J \subseteq [n]} \sum_{J' \subseteq I} (-1)^{|J'|} f(0^*_J) = \sum_{J \subseteq [n]} \sum_{K \subseteq [n] \setminus J} (-1)^{|K|} f(0^*_K)
\]
\[
= \sum_{J \subseteq [n]} \left( \sum_{K \subseteq [n] \setminus J} (-1)^{|K|} \right) f(0^*_J).
\]
Since a nonempty finite set has the same number of subsets of odd cardinality as subsets of even cardinality, the coefficient $\sum_{K \subseteq [n] \setminus J} (-1)^{|K|}$ of $f(0^*_J)$ above is 0 unless $J = [n]$. Thus the sum reduces to $f(0^*_{[n]}) = f(x)$, and this proves the theorem.

The following proposition provides a useful criterion of decomposability.

**Proposition 3.3.** A function $f: A^n \to B$ is $k$-decomposable if and only if $\Delta_k f(0) = 0$ for all $a \in A^n$ and $I \subseteq [n]$ with more than $k$ elements.

**Proof.** Sufficiency follows directly from Proposition 3.2: clearly, the essential arity of the function $x \mapsto \Delta_k f(0)$ is at most $|I|$. Therefore, if $\Delta_k f(0)$ vanishes whenever $|I| > k$, then $f$ is a decomposition into a sum of essentially at most $k$-ary functions.

For necessity, let us suppose that $f = f_1 + \cdots + f_s$, where $\text{ess } f_i \leq k$ for $i \in [s]$. If $|I| > k$, then $I$ contains (the index of) at least one of the inessential variables of $f_i$, hence $\Delta_k f_i$ is constant 0 for every $a \in A^n$ and $i \in [s]$. Since $\Delta_k f = \Delta_k f_1 + \cdots + \Delta_k f_s$, we can conclude that $\Delta_k f$ is constant 0 as well. In particular, we have $\Delta_k f(0) = 0$.

The following two theorems constitute the main results of this section, and they show a strong dichotomy of abelian groups with respect to the decomposability of functions determined by oddsupp.

**Theorem 3.4.** If $A$ is a finite set and $B$ is an abelian group of exponent $2^e$, then every function $f: A^n \to B$ determined by oddsupp is $(|A| + e - 2)$-decomposable.

**Proof.** Suppose that $f = \oplus_x \varphi$ for some $\varphi: \mathcal{P}_n(A) \to B$. By Proposition 3.3 it suffices to verify that $\Delta_k f(0) = 0$ whenever $|I| \geq |A| + e - 1$. Let $\{a_i : i \in I\} := \{b_1, \ldots, b_t\}$ ($b_i \neq b_j$ whenever $i \neq j$), and let $B_i := \{i \in I : a_i = b_i\}$. Thus $|B_j|$ is the number of occurrences of $b_j$ in $a(I)$; hence $|B_1| + \cdots + |B_t| = |I|$ and $t \leq |A|$. Using Proposition 3.4 we can expand $\Delta_k f(0)$ as

\[
\Delta_k f(0) = \sum_{J \subseteq I} (-1)^{|J'|} f(0^*_J) = \sum_{J \subseteq I} (-1)^{|J'|} \varphi(\text{oddsupp}(0^*_J)).
\]

Let us fix a set $S \subseteq A$ that appears as oddsupp($0^*_J$) in the above sum.

Assume first that $0 \in \{b_1, \ldots, b_t\}$, say $b_t = 0$. Then oddsupp($0^*_J$) = $S$ if and only if $|J \cap B_t|$ is odd whenever $b_j \in S$ and $|J \cap B_j|$ is even whenever $b_j \notin S$ for $j = 1, \ldots, t - 1$ (note that $J \cap B_t$ is irrelevant in determining $0^*_J$). Since the number of subsets of $B_t$ of even cardinality equals the number of subsets of $B_t$ of odd cardinality, it holds that the number of sets $J$ satisfying oddsupp($0^*_J$) = $S$ that have an even cardinality equals the number of those that have an odd cardinality. Hence, the terms corresponding to such sets $J$ will cancel each other in (4).

Assume now that $0 \notin \{b_1, \ldots, b_t\}$. Then clearly $t \leq |A| - 1$. Similarly, as in the previous case, we have that oddsupp($0^*_J$) = $S$ if and only if $|J \cap B_t|$ is odd.
whenever \( b_j \in S \) and \(|J \cap B_j|\) is even whenever \( b_j \notin S \) for \( j = 1, \ldots, t \). Therefore, the number of sets \( J \subseteq I \) satisfying \( \text{oddsupp}(0^a_J) = S \) is
\[
2^{|B_1|-1} \cdots 2^{|B_t|-1} = 2^{|B_1|+\cdots+|B_t|-t} = 2^{|I|-t}.
\]
Moreover, the parity of \(|J|\) is determined by \( S \). Therefore, all occurrences of \( \varphi(S) \) in (4) have the same sign.

By the argument above, \( \Delta^a_J f(0) \) can be written as a sum of finitely many terms of the form \( \pm 2^{|I|-t}\varphi(S) \), where \( t \leq |A| - 1 \). Since \(|I| \geq |A| + e - 1 \), the coefficient \( 2^{|I|-t} \) is a multiple of \( 2^e \); hence \( \pm 2^{|I|-t}\varphi(S) = 0 \) independently of the value of \( \varphi(S) \). We conclude that \( \Delta^a_J f(0) = 0 \), as claimed.

As the following example shows, Theorem 3.4 cannot be improved and the number \(|A| + e - 2 \) cannot be decreased. More precisely, for every finite set \( A \) with at least two elements, for every abelian group \( B \) of exponent \( 2^e \), and for every \( n > |A| + e - 3 \), there exists a function \( f : A^n \to B \) that is determined by \( \text{oddsupp} \) but is not \((|A| + e - 3)\)-decomposable.

**Example 3.5.** Let \( A = \{0, 1, \ldots, \ell\} \), and let \( B \) be an arbitrary abelian group of exponent \( 2^e \). Fix an element \( b \in B \) of order \( 2^e \). Let \( \varphi : \mathcal{P}(A) \to B \) be defined by
\[
\varphi(T) = \begin{cases} 
b, & \text{if } T \supseteq A \setminus \{0\}, 
0, & \text{otherwise},
\end{cases}
\]
let \( n \geq \ell + e - 1 \), and let \( f : A^n \to B \) be given by \( f(x) = \#(x) \).

To see that \( f \) is not \((|A| + e - 3)\)-decomposable, by Proposition 3.3 it suffices to find \( I \subseteq [n] \) and \( a \in A^n \) such that \(|I| = |A| + e - 2 = \ell + e - 1 \) and \( \Delta^a_I f(0) \neq 0 \). To see this, let
\[
a := (1, 2, \ldots, \ell - 1, \ell, \ldots, \ell, 0, \ldots, 0),
\]
and let \( I := \{1, 2, \ldots, \ell + e - 1\} \). Consider the expansion of \( \Delta^a_I f(0) \) as in (4). We can verify that for all \( J \subseteq I \),
\[
f(0^a_J) = \begin{cases} 
b, & \text{if } J \supseteq \{1, \ldots, \ell - 1\} \text{ and } |J \cap \{\ell, \ldots, \ell + e - 1\}| \text{ is odd}, 
0, & \text{otherwise}.
\end{cases}
\]
From this it follows that the number of sets \( J \subseteq I \) satisfying \( f(0^a_J) = b \) is \( 2^{e-1} \). Therefore, we have
\[
\Delta^a_I f(0) = (-1)^{e-1}2^{e-1}b \neq 0,
\]
where the inequality holds because the order of \( b \) is \( 2^e \).

**Theorem 3.6.** If \( A \) is a finite set with at least two elements and \( B \) is an abelian group whose exponent is not a power of 2, then for each \( n \) there exists a function \( f : A^n \to B \) determined by \( \text{oddsupp} \) that is not decomposable.

**Proof.** If the exponent of \( B \) is not a power of 2, then it has an element \( b \) whose order is not a power of 2 (possibly infinite). Let us consider first the special case \( A = \{0, 1\} \). For any \( x \in A^n \) let \( w(x) \) denote the Hamming weight of \( x \), i.e., the number of 1’s appearing in \( x \). Let \( f_0 : A^n \to B \) be the function defined by
\[
f_0(x) = \begin{cases} 
b, & \text{if } w(x) \text{ is even}, 
0, & \text{if } w(x) \text{ is odd}.
\end{cases}
\]
Let us compute $\Delta^1_{[n]} f_0(0)$ with the help of Proposition 3.1

$$\Delta^1_{[n]} f_0(0) = \sum_{J \subseteq [n]} (-1)^{|n\setminus J|} f_0(0_J^J) = (-1)^n \sum_{J \subseteq [n]} (-1)^{|J|} f_0(0_J^J).$$

Since $w(0^J) = |J|$, the above sum consists of $2^{n-1}$ many $b$'s and $2^{n-1}$ many $0$'s. Thus $\Delta^1_{[n]} f_0(0) = (-1)^n 2^{n-1} b \neq 0$, as $\text{ord}(b)$ does not divide $(-1)^n 2^{n-1}$. Now Proposition 3.3 shows that $f_0$ is not $(n - 1)$-decomposable.

Considering the general case, let $0$ and $1$ be two distinguished elements of $A$, and let $f : A^n \to B$ be any function that is determined by $\text{oddsupp}$ such that $f|_{\{0,1\}^n} = f_0$. Then $f$ is not decomposable, since any decomposition of $f$ would give rise to a decomposition of $f|_{\{0,1\}^n}$.

\[\square\]

**Corollary 3.7.** Let $A$ be a finite set with at least two elements, and $B$ be an abelian group. All functions $f : A^n \to B$ determined by $\text{oddsupp}$ are decomposable if and only if the exponent of $B$ is a power of $2$.

As the following example shows, decomposability is not guaranteed when $A$ is infinite, no matter what the exponent of $B$ is.

**Example 3.8.** Let $A$ be an infinite set, let $B$ be an abelian group and let $0 \neq b \in B$. Fix $n \geq 2$, and let $S := \{s_1, \ldots, s_n\} \subseteq A \setminus \{0\}$ with $|S| = n$. Define $f : A^n \to B$ by the rule

$$f(x) = \begin{cases} b, & \text{if } \{x_1, \ldots, x_n\} = S, \\ 0, & \text{otherwise.} \end{cases}$$

It is clear that $f$ is determined by $\text{oddsupp}$. Computing $\Delta^n_{[n]} f(0)$ for $a := (s_1, \ldots, s_n)$ as in (3.3), we obtain $\Delta^n_{[n]} f(0) = b \neq 0$. Hence $f$ is not decomposable by Proposition 3.3.

**Remark 3.9.** Theorem 2.6 asserts that if $B$ is a Boolean group and $n > |A|$, then every function $f : A^n \to B$ determined by $\text{oddsupp}$ is $(n - 2)$-decomposable. Theorem 3.4 gives a stronger result as it provides a decomposition into a sum of functions whose essential arity has an upper bound that depends only on $A$ and $B$ (and not on $n$). Theorem 2.6 implies that if $\exp(B)$ is not a power of $2$, then even the weakest kind of decomposability (namely, $(n - 1)$-decomposability) fails to hold for all functions $f : A^n \to B$ determined by $\text{oddsupp}$.

**4. The case of Boolean groups**

In this section we assume that $A$ is a finite set with a distinguished element $0$ and $(B; +)$ is a Boolean group with neutral element $0$. Applying Theorem 3.4 to this case (with $e = 1$), we see that every function $f : A^n \to B$ determined by $\text{oddsupp}$ is $(|A| - 1)$-decomposable. Here we will provide a canonical, highly symmetric decomposition of such functions and show that it is unique.

If $n > |A|$, then Theorem 2.6 provides a decomposition of $f$ into a sum of functions of essential arity at most $n - 2$. Each summand $\underline{\otimes}_s(\underline{x})_I$ is a function determined by $\text{oddsupp}$, and if $|I| > |A|$, then we can apply Theorem 2.6 to decompose $\underline{\otimes}_s(\underline{x})_I$ into a sum of functions of essential arity at most $|I| - 2$. Repeating this process as long as we have summands of essential arity greater than $|A|$, we end up with an $|A|$-decomposition of $f$. If the parities of $|A|$ and $n$ are different, then this is already an $(|A| - 1)$-decomposition. By counting how many times a given
summand $\mathcal{S}_\varphi(x_i)$ appears, we arrive at decomposition (3) given below in Theorem 4.1. If the parities of $|A|$ and $n$ are equal, then we have to further decompose the summands of essential arity $|A|$. We then get the more refined decomposition (7) given below in Theorem 4.2. Note that in these theorems we assume that $B$ is finite. However, as we will see in Remark 4.3 the general case can be easily reduced to the case of finite groups.

**Theorem 4.1.** Let $f : A^n \to B$, where $B$ is a finite Boolean group, $A$ is a finite set, and $n - |A| = 2t + 1 > 0$. Then $f$ is determined by oddsupp if and only if $f$ is of the form

$$f(x) = \sum_{i=1}^{\lfloor \frac{n}{2} \rfloor} \sum_{I \subseteq [n] \atop |I| = n-2i} \left( \begin{array}{c} i-1 \\ t \end{array} \right) \mathcal{S}_\varphi(x_i),$$

for some map $\varphi : P_n'(A) \to B$. Moreover, $\varphi$ is uniquely determined by $f$.

**Proof.** Let $g_\varphi : A^n \to B$ denote the function given by the right-hand side of (5). Let us note that since $n > |A|$ and $n - |A|$ is odd, $P_n'(A)$ contains all subsets of $A$ whose complement has an odd number of elements. Observe also that in (5) $I$ ranges over subsets of $[n]$ of size $|A|-1, |A|-3, \ldots$; hence (5) provides an $(|A|-1)$-decomposition of $f$. Clearly, for such sets $I$ we have oddsupp$(x_i) \in P_n'(A)$.

To prove the theorem, it suffices to show that the following three statements hold:

(i) the number of functions $f : A^n \to B$ that are determined by oddsupp is the same as the number of maps $\varphi : P_n'(A) \to B$;

(ii) $g_\varphi$ is determined by oddsupp for every $\varphi : P_n'(A) \to B$;

(iii) if $\varphi_1 \neq \varphi_2$ then $g_{\varphi_1} \neq g_{\varphi_2}$.

The existence and uniqueness of the decomposition then follows by a simple counting argument: the functions $f : A^n \to B$ determined by oddsupp are in a one-to-one correspondence with the functions $g_\varphi$. (Alternatively, the existence could be proved by repeated applications of Theorem 2.6, as explained above.)

Statement (i) is clear: the number of functions $f : A^n \to B$ that are determined by oddsupp is $|B|^{|P_n'(A)|}$, the same as the number of maps $\varphi : P_n'(A) \to B$.

To see that (ii) holds, observe that each $g_\varphi$ is a totally symmetric function. Hence, by Fact 2.3 it suffices to prove that $g_\varphi(x_1, x_1, x_1, \ldots, x_n)$ does not depend on $x_1$. Let $x = (x_1, x_1, x_3, \ldots, x_n)$ and let $I$ be a set appearing in the summation in (5) such that $1 \in I$ and $2 \notin I$. Then $I' := I \triangle \{1, 2\} = (I \setminus \{1\}) \cup \{2\}$ ($\triangle$ denotes the symmetric difference) appears as well, since it has the same cardinality as $I$. As oddsupp$(x_i) =$ oddsupp$(x_i)$, we have $\mathcal{S}_\varphi(x_i) = \mathcal{S}_\varphi(x_i)$, thus these two summands will cancel each other. The remaining sets $I$ either contain both 1 and 2 or neither of them. In the first case, oddsupp$(x_i) =$ oddsupp$(x_i \setminus \{1, 2\})$, and hence $\mathcal{S}_\varphi(x_i)$ does not depend on $x_1$, whereas in the second case $x_1$ does not appear in $\mathcal{S}_\varphi(x_i)$ at all. Thus $g_\varphi(x_1, x_1, x_3, \ldots, x_n)$ does not depend on $x_1$, which shows that (iii) holds.

To prove (iii), suppose on the contrary that there exist maps $\varphi_1, \varphi_2 : P_n'(A) \to B$ such that $\varphi_1 \neq \varphi_2$ but $g_{\varphi_1} = g_{\varphi_2}$. Then for $\varphi = \varphi_1 + \varphi_2$ we have $g_{\varphi} = g_{\varphi_1} + g_{\varphi_2} \equiv 0$.
by Fact 2.4 that is,

$$\sum_{i=t+1}^{\frac{n+1}{2}} \sum_{I \subseteq [n]} \left( \frac{i-1}{t} \right) 2^{|I|} \phi(x|_{I}) = 0$$

for all \( x \in A^n \). Moreover, since \( \phi_1 \neq \phi_2 \), there exists an \( S \in \mathcal{P}_n(A) \) with \( \phi(S) \neq 0 \). Let us choose \( S \) to be minimal with respect to this property, i.e., \( \phi(S) \neq 0 \), but \( \phi \) vanishes on all proper subsets of \( S \).

Suppose first that \( S \) is nonempty, say \( S = \{ s_1, \ldots, s_{n-2r} \} \). Since \( n-|A| = 2t+1 \), we have that \( t \leq r-1 \). Let us examine the left-hand side of (6) for

\[ x := (s_1, \ldots, s_1, s_2, \ldots, s_{n-2r}) \in A^n. \]

Observe that \( \text{oddsupp}(x|_{I}) \subseteq S \). If \( \text{oddsupp}(x|_{I}) \subseteq S \), then \( \phi_{\phi}(x|_{I}) = 0 \) by the minimality of \( S \). If \( \text{oddsupp}(x|_{I}) = S \), then \( \phi_{\phi}(x|_{I}) = \phi(S) \neq 0 \). The latter is the case if and only if \( I \) is a proper superset of \( \{ 2r+2, \ldots, n \} \) of cardinality \( n-2i \) for some \( i \). The number of sets \( I \subseteq [n] \) with \( |I| = n-2i \) and \( I \supset \{ 2r+2, \ldots, n \} \) is \( \binom{n}{2} \). Hence the left-hand side of (6) equals

\[ \sum_{i=t+1}^{r} \binom{2r+1}{2i} \binom{i-1}{t} \phi(S) \]

Since \( r > t+1 \), the coefficient \( \sum_{i=t+1}^{r} \binom{2r+1}{2i} \binom{i-1}{t} \) of \( \phi(S) \) is odd according to Theorem 2.7 (for \( m = 2r+1 \)). Therefore, taking into account that \( B \) is a Boolean group, we can conclude that the left-hand side of (6) is \( \phi(S) \neq 0 \), which is a contradiction.

Suppose then that \( S \) is empty. Choose \( x := (s_1, \ldots, s_1) \) for an arbitrary \( s_1 \in A \). Since \( S \in \mathcal{P}_n(A) \), \( n \) is even and hence each \( I \) occurring in (6) is of even cardinality. Whenever \( |I| \) is even, \( \text{oddsupp}(x|_{I}) = \emptyset \) and \( \phi_{\phi}(x|_{I}) = \phi(S) \). Therefore, the left-hand side of (6) becomes

\[ \sum_{i=t+1}^{\frac{n}{2}} \binom{n}{2i} \binom{i-1}{t} \phi(S) , \]

which equals \( \phi(S) \) by Theorem 2.7 (for \( m = n \)). This yields the desired contradiction, and the proof of (4b) is now complete.

**Theorem 4.2.** Let \( f: A^n \rightarrow B \), where \( B \) is a finite Boolean group, \( A \) is a finite set, and \( n-|A| = 2t > 0 \). Then \( f \) is determined by oddsupp if and only if \( f \) is of the form

$$f(x) = \sum_{i=t+1}^{\frac{n+1}{2}} \sum_{|I| = n-2i} \left( \frac{i-1}{t} \right) 2^{|I|} \phi(x|_{I}) + \sum_{k=t+1}^{\frac{n+1}{2}} \sum_{|K| = n-2k+1} \left( \frac{2k-1}{2t} \right) 2^{|K|} \phi(x|_{K}).$$

for some map \( \phi: \mathcal{P}(A) \rightarrow B \) satisfying \( \phi(S) = \phi(S \triangle \{0\}) \) for every \( S \in \mathcal{P}(A) \). Moreover, \( \phi \) is uniquely determined by \( f \).
Thus the left-hand side of (8) reduces to $r > t$. By Theorem 2.8, the coefficient of the first sum of (8) equals 0 in the second sum of (8), then $\sum_{k=0}^{n-2t+1} (2k-1) \varnothing(x|_{K}) = 0$.

The fact that the right-hand side of (7) is determined by oddsupp can be proven in a similar way, and for the uniqueness it suffices to prove that if

$$
(8) \quad \sum_{i=t+1} \sum_{I \subseteq [n], |I|=n-2t} \binom{i-1}{t} \varnothing(x|_{I}) + \sum_{k=t+1}^{n+1} \sum_{K \subseteq [n], |K|=n-2k+1} \binom{2k-1}{2t} \varnothing(x|_{K}) = 0
$$

for all $x \in A^n$, then $\varnothing|_{P_n^r(A)}$ is identically 0.

Suppose, for the sake of contradiction, that there exists an $S \in P_n^r(A)$ such that $\varnothing(S) \neq 0$, and let $n-2r$ be the cardinality of the smallest such $S$. If $r = t$, then $\varnothing(A) = \varnothing(A \setminus \{0\}) \neq 0$, and $\varnothing$ is zero on all other subsets of $A$. Let $A = \{0, a_1, \ldots, a_{\ell}\}$, where $\ell = n-2t-1$, and let $x = (0, 0, 0, \ldots, a_1, a_2) \in A^n$, where the number of 0’s is $2t+1$. Then, for any set $I$ appearing in the first summation of (8), we have $A \setminus \{0\} \not\subseteq \text{oddsupp}(x|_{I})$; hence $\varnothing(x|_{I}) = 0$. Similarly, $\varnothing(x|_{K}) = 0$ for all sets $K$ appearing in (8), except for $K = \{2t+2, 2t+3, \ldots, n\}$, where $\varnothing(x|_{K}) = \varnothing(A \setminus \{0\})$. Thus the left-hand side of (8) equals $\varnothing(A \setminus \{0\}) \neq 0$, contrary to our assumption.

Let us now consider the case $r > t$, and let us suppose first that there exists a set $S \in P_n^r(A)$ of cardinality $n-2r$ such that $\varnothing(S) \neq 0$ and $0 \in S$, say $S = \{s_1, \ldots, s_{n-2r}\}$ with $s_1 = 0$. Let $T$ be a subset of $S$. By the minimality of $|S|$, if $T \in P_n^r(A)$ then we have $\varnothing(T) \neq 0$ if and only if $T = S$. Similarly, if $T \not\in P_n^r(A)$ then we have $\varnothing(T) = 0$ if and only if $T = S \setminus \{0\}$. (Indeed, if $T \not= S \setminus \{0\}$, then $T \triangle \{0\} \in P_n^r(A)$ is a proper subset of $S$. Hence $\varnothing(T) = \varnothing(T \triangle \{0\}) = 0$.)

Let us examine the left-hand side of (8) for $x := (s_1, \ldots, s_1, s_{2}, \ldots, s_{n-2r}) \in A^n$. The same argument as in the proof of Theorem 4.1 shows that the first sum of (8) equals

$$
\varnothing(S) \sum_{i=t+1}^{r} \binom{2r+1 - 2i}{2i} \binom{i-1}{t} \varnothing(S),
$$

which is $\varnothing(S)$ by Theorem 2.7, since $r \geq t+1$. If $K$ is a set of size $n-2k+1$ appearing in the second sum of (8), then $\varnothing(x|_{K}) = \varnothing(S \setminus \{0\}) = \varnothing(S)$ if $K \supseteq \{2r+2, \ldots, n\}$, and $\varnothing(x|_{K}) = 0$ otherwise. The number of such sets $K$ is $\binom{2r+1}{2k-1}$, thus the second sum on the left-hand side of (8) equals

$$
\varnothing(S) \sum_{k=t+1}^{r+1} \binom{2r+1 - 2k+1}{2k-1} \binom{2k-1}{2t} \varnothing(S).
$$

By Theorem 2.8 the coefficient of $\varnothing(S)$ here is $\binom{2r+1}{2k-1} 2^{2r-2t}$, which is even since $r > t$. Thus the left-hand side of (8) reduces to $\varnothing(S)$, contradicting our assumption.

In the remaining case we have $r > t$ and for all $S \in P_n^r(A)$ of cardinality $n-2r$ we have $0 \not\in S$ whenever $\varnothing(S) \neq 0$. Let $S = \{s_1, \ldots, s_{n-2r}\}$ be such a set, and
let $T \subseteq S$. If $T \in \mathcal{P}_n'(A)$, then we have $\varphi(T) \neq 0$ if and only if $T = S$ by the minimality of $|S|$. Similarly, if $T \notin \mathcal{P}_n'(A)$, then we have $\varphi(T) = 0$. (Indeed, if $T \notin \mathcal{P}_n'(A)$ then $T \cup \{0\} = T \triangle \{0\} \in \mathcal{P}_n'(A)$ and $|T \triangle \{0\}| \leq |S|$. On the other hand, if $\varphi(T \triangle \{0\}) = \varphi(T) \neq 0$ then $|T \triangle \{0\}| \geq |S|$ by the minimality of $|S|$. Thus we have $|T \triangle \{0\}| = |S| = n - 2r$, hence $T \triangle \{0\}$ is a set in $\mathcal{P}_n'(A)$ with cardinality $n - 2r$ such that $\varphi(T \triangle \{0\}) \neq 0$ and $0 \in T \triangle \{0\}$, and then replacing $S$ by $T \triangle \{0\}$ we come back to the previous case.)

Let us choose $x := (s_1, \ldots, s_1, s_2, \ldots, s_{n-2r}) \in A^n$ as before, and examine the summands in $\bigoplus$. For each $K$ appearing in the second sum, $\text{oddsupp}(x|_K) \subseteq S$ and $\text{oddsupp}(x|_K) \notin \mathcal{P}_n'(A)$, thus $\text{oddsupp}(x|_K) = 0$. For each $I$ appearing in the first sum, we have $\text{oddsupp}(x|_I) = \varphi(S) \neq 0$ if $I$ is a proper superset of $\{2r+2, \ldots, n\}$; otherwise $\text{oddsupp}(x|_I) \subseteq S$, and so $\text{oddsupp}(x|_I) = 0$. Therefore, using Theorem 2.7 as before, we can conclude that the left-hand side of $\bigoplus$ equals $\varphi(S)$, and this contradiction finishes the proof of the theorem.

Remark 4.3. Theorems 4.1 and 4.2 still hold for infinite Boolean groups $B$. To see this, let $f: A^n \to B$ be a function that is determined by $\text{oddsupp}$, where $A$ is a finite set and $B$ is a possibly infinite Boolean group, and let $R \subseteq B$ be the range of $f$. Since $R$ is finite, the subgroup $[R] \leq B$ generated by $R$ is also finite. (The free Boolean group on $r$ generators has cardinality $2^r$.) Applying Theorems 4.1 and 4.2 to $f: A^n \to [R]$, we obtain the desired decomposition of $f$. To show the uniqueness, suppose that $\varphi_1, \varphi_2: \mathcal{P}(A) \to B$ both yield the function $f$. Then we can replace $B$ by its subgroup generated by the union of the ranges of $\varphi_1$ and $\varphi_2$, and apply the uniqueness parts of Theorems 4.1 and 4.2.

5. Illustration: Operations over the Three-Element Set

We saw in Theorem 2.1 that a Boolean function of essential arity at least 4 has arity gap 2 if and only if it is a sum of essentially at most unary functions. Alternatively, this fact follows from the results of the previous section together with Willard’s Theorem 2.5. More generally, Theorems 4.1 and 4.2 can be applied to describe polynomial functions over finite fields of characteristic 2 with arity gap 2. In [9] we provided a simpler and more explicit description of such polynomial functions. In this section we show how Theorems 4.1 and 4.2 can be used to describe functions $f: \mathbb{Z}_3^n \to \mathbb{Z}_3$ of arity at least 4 with gap $f = 2$. Since $\mathbb{Z}_3$ is not a Boolean group, we cannot apply these theorems directly. First we need to embed $\mathbb{Z}_3$ into a Boolean group. To this extent, let $A := \mathbb{Z}_3 = \{0, 1, 2\}$ with the usual field operations $+$ and $\cdot$, and $B := \mathcal{P}(A)$ with the symmetric difference operation $\oplus$. We use the notation $\oplus$ instead of the more common $\Delta$ in order to emphasize that this is a Boolean group operation on $B$ (which was denoted by $+$ before). The neutral element of $(A; +)$ is 0, and the neutral element of $(B; \oplus)$ is the empty set $\emptyset$. We identify the elements of $A$ with the corresponding one-element sets, i.e., we simply write $a$ instead of $\{a\}$ for $a \in A$. In this way, $A$ becomes a subset (but, of course, not a subgroup) of $B$.

Let $f: A^n \to B$, where $n \geq 4$ is even. Then we have $n = 2t + 4$ in Theorem 4.1 and the summation in (1) runs over the subsets of $[n]$ of size 2 (for $i = t + 1$) and of size 0 (for $i = t + 2$). The corresponding coefficients $(t^{-1})^i$ are $\binom{t}{i}$ and $\binom{t+1}{i}$, respectively. Thus $(t^{-1})^i \varphi(x|_I) = \text{oddsupp}(x|_I)$ whenever $|I| = 2$ or $I = \emptyset$ and $t$ is even (i.e., $n$ is divisible by 4); on the other hand, if $I = \emptyset$ and $t$ is odd, then...
\[(i^{-1}) \otimes \phi(x)_J = 0.\] Therefore, \((5)\) takes one of the following two forms, depending on the residue of \(n\) modulo 4 (the summation indices \(i\) and \(j\) always run from 1 to \(n\), unless otherwise indicated):

\[
f(x) = \bigoplus_{i<j} \phi(\text{o DDSupp}(x_i, x_j)) \oplus \phi(\emptyset) \quad \text{if } n \equiv 0 \pmod{4},
\]

\[
f(x) = \bigoplus_{i<j} \phi(\text{o DDSupp}(x_i, x_j)) \quad \text{if } n \equiv 2 \pmod{4}.
\]

(Note that \(\phi(\text{o DDSupp}(x_i, x_j)) = \phi(\{x_i, x_j\})\) if \(x_i \neq x_j\), and \(\phi(\text{o DDSupp}(x_i, x_j)) = \phi(\emptyset)\) if \(x_i = x_j\).)

If \(n\) is odd, then we can apply Theorem 4.2. In this case we have \(n = 2t + 3\), and in the first summation of \((7)\) \(I\) is a one-element set \((i = t+1)\) and the corresponding coefficient is \(\binom{t^{-1}}{t^{-1}} = 0\). The second summation, \(K\) is either a two-element set \((k = t + 1)\) or the empty set \((k = t + 2)\). The corresponding coefficients \(\binom{2k-1}{2t}\) are \(2k+1\) and \(2k+3\) as explained above. We work out the details for the above decompositions.

**Theorem 5.1.** Let \(f : \mathbb{Z}_3^n \to \mathbb{Z}_3\) be a function of arity at least 4. Then gap \(f = 2\) if and only if there exists a unary polynomial \(p = ax^2 + bx + c \in \mathbb{Z}_3[x]\) and a constant \(d \in \mathbb{Z}_3\), which are uniquely determined by \(f\), such that

\[
f(x) = \bigoplus_{i<j} (x_i - x_j)^2 p(x_i + x_j) + d \quad \text{if } n \equiv 0 \pmod{4},
\]

\[
f(x) = \bigoplus_{i<j} (x_i - x_j)^2 p(x_i + x_j) + d \oplus \bigoplus_i (p(x_i) + d) \quad \text{if } n \equiv 1 \pmod{4},
\]

\[
f(x) = \bigoplus_{i<j} (x_i - x_j)^2 p(x_i + x_j) + d \quad \text{if } n \equiv 2 \pmod{4},
\]

\[
f(x) = \bigoplus_{i<j} (x_i - x_j)^2 p(x_i + x_j) + d \oplus \bigoplus_i (p(x_i) + d) \oplus d \quad \text{if } n \equiv 3 \pmod{4}.
\]

Otherwise we have gap \(f = 1\).

**Proof.** Let \(A := \mathbb{Z}_3\) and \(B := \mathcal{P}(\mathbb{Z}_3)\) as explained above. We work out the details only for the case \(n \equiv 3 \pmod{4}\), the other cases are similar. First let us consider the function

\[f_1(x) = \bigoplus_i (p(x_i) + d).\]
It is clear that this function is totally symmetric, and \( f_1(x_1, x_1, x_3, \ldots, x_n) \) does not depend on \( x_1 \), since

\[
f_1(x_1, x_1, x_3, \ldots, x_n) = (p(x_1) + d) \oplus (p(x_1) + d) \oplus \bigoplus_{i=3}^{n}(p(x_i) + d) = \bigoplus_{i=3}^{n}(p(x_i) + d).
\]

Therefore, \( f_1 \) is determined by \( \text{oddsupp} \) by Fact 2.3. Hence \( f_1(x) = \varphi_1(\text{oddsupp}(x)) \) for some map \( \varphi_1: \mathcal{P}_n'(A) \to B \). Observe that \( \mathcal{P}_n'(A) = \{\{0\}, \{1\}, \{2\}, \{0, 1, 2\}\} \).

Thus, in order to determine \( \varphi_1 \), it suffices to compute the following four values of \( f_1 \):

\[
\varphi_1(\{0\}) = f_1(0, \ldots, 0) = \bigoplus_{i=1}^{n}(p(0) + d) = p(0) + d = c + d,
\]

\[
\varphi_1(\{1\}) = f_1(1, \ldots, 1) = \bigoplus_{i=1}^{n}(p(1) + d) = p(1) + d = a + b + c + d,
\]

\[
\varphi_1(\{2\}) = f_1(2, \ldots, 2) = \bigoplus_{i=1}^{n}(p(2) + d) = p(2) + d = a + 2b + c + d,
\]

\[
\varphi_1(\{0, 1, 2\}) = f_1(0, \ldots, 0, 1, 2) = \bigoplus_{i=1}^{n-2}(p(0) + d) \oplus (p(1) + d) \oplus (p(2) + d)
\]

\[
= (p(0) + d) \oplus (p(1) + d) \oplus (p(2) + d)
\]

\[
= (c + d) \oplus (a + b + c + d) \oplus (a + 2b + c + d).
\]

We now analyze the function

\[
f_2(x) = \bigoplus_{i<j}((x_i - x_j)^2p(x_i + x_j) + d)
\]

in a similar manner. Examining \( f_2(x_1, x_1, x_3, \ldots, x_n) \) we can see that the summands corresponding to \( i = 1, j \geq 3 \) cancel the summands corresponding to \( i = 2, j \geq 3 \), while the summand corresponding to \( i = 1, j = 2 \) is \((x_1 - x_1)^2p(x_1 + x_1) + d = d\). Hence

\[
f_2(x_1, x_1, x_3, \ldots, x_n) = d \oplus \bigoplus_{3 \leq i < j}((x_i - x_j)^2p(x_i + x_j) + d),
\]

which clearly does not depend on \( x_1 \). Since \( f_2 \) is totally symmetric, we can conclude that \( f_2 \) is determined by \( \text{oddsupp} \). Therefore, there is a map \( \varphi_2: \mathcal{P}_n'(A) \to B \) such that \( f_2(x) = \varphi_2(\text{oddsupp}(x)) \). For any \( a \in A \) we have

\[
\varphi_2(\{a\}) = f_2(a, \ldots, a) = \bigoplus_{i<j}((a - a)^2p(a + a) + d) = \binom{n}{2}d = d,
\]
where the last equality holds, because \( \binom{n}{2} \) is an odd number by the assumption that \( n \equiv 3 \mod 4 \). To find \( \varphi_2(\{0, 1, 2\}) \), we can proceed as follows:

\[
\varphi_2(\{0, 1, 2\}) = f_2(0, \ldots, 0, 1, 2) = \bigoplus_{i<j \leq n-2} \left((0-0)^2 p(0+0) + d\right)
+ \bigoplus_{i=1}^{n-2} \left((0-1)^2 p(0+1) + d\right)
+ \bigoplus_{i=1}^{n-2} \left((0-2)^2 p(0+2) + d\right)
+ \left((1-2)^2 p(1+2) + d\right)
= (a + b + c + d) \oplus (a + 2b + c + d) \oplus (c + d).
\]

(Here we used the fact that \( \binom{n-2}{2} \) is even and \( n-2 \) is odd.)

The expression given for \( f \) in the theorem is \( f_1(x) \oplus f_2(x) \oplus d \), and from the above calculations it follows that this function is determined by oddsupp, namely, \( f_1(x) \oplus f_2(x) \oplus d = \varphi(\text{oddsupp}(x)) \), where

\[
\varphi(\{0\}) = \varphi_1(\{0\}) \oplus \varphi_2(\{0\}) \oplus d = (c + d) \oplus d = c + d,
\]

\[
\varphi(\{1\}) = \varphi_1(\{1\}) \oplus \varphi_2(\{1\}) \oplus d = (a + b + c + d) \oplus d = a + b + c + d,
\]

\[
\varphi(\{2\}) = \varphi_1(\{2\}) \oplus \varphi_2(\{2\}) \oplus d = (a + 2b + c + d) \oplus d = a + 2b + c + d,
\]

\[
\varphi(\{0, 1, 2\}) = \varphi_1(\{0, 1, 2\}) \oplus \varphi_2(\{0, 1, 2\}) \oplus d
= (c + d) \oplus (a + b + c + d) \oplus (a + 2b + c + d)
\]

\[
\oplus (a + b + c + d) \oplus (a + 2b + c + d) \oplus (c + d) \oplus d = d.
\]

Observe that the range of \( \varphi \) is a subset of \( A \). Hence \( f_1(x) \oplus f_2(x) \oplus d \) is a function from \( A^n \) to \( A \).

Let us consider the linear transformation

\[
L: \mathbb{Z}_3^4 \rightarrow \mathbb{Z}_3^4, \quad (a, b, c, d) \mapsto (c + d, a + b + c + d, a + 2b + c + d, d).
\]

The determinant of \( L \) is 1; hence \( L \) is a bijection. This means that the maps \( \varphi: \mathcal{P}_n^a(A) \rightarrow B \) that are of the above form are in a one-to-one correspondence with the 4-tuples over \( A \), i.e., there are \( 3^4 = 81 \) such maps. The number of functions \( f: A^n \rightarrow A \) that are determined by oddsupp is also 81. Hence we can conclude by a simple counting argument that for any such \( f \) there exists a unique tuple \( (a, b, c, d) \in A^4 \) such that \( f(x) = f_1(x) \oplus f_2(x) \oplus d \).

Let us observe that when computing the value of a function of the form given in Theorem 5.1 we do not have to “leave” \( \mathbb{Z}_3 \): using the fact that \( \oplus \) is commutative and associative and it satisfies \( u \oplus u \oplus v = v \) for any \( u, v \in \mathbb{Z}_3 \), we can always perform the calculations in such a way that we work only with singleton elements of \( B \). It is not even necessary to know that \( B \) is the power set of \( \mathbb{Z}_3 \), it could be any Boolean group that contains \( \mathbb{Z}_3 \) as a subset. To illustrate this point, let us compute \( f(0, 0, 1, 2) \) for the function

\[
f(x_1, x_2, x_3, x_4) = \bigoplus_{i<j} ((x_i - x_j)^2 p(x_i + x_j) + d) \oplus d
\]

that corresponds to the case \( n = 4 \) with \( a = 1, b = c = d = 2 \) in Theorem 5.1.

\[
f(0, 0, 1, 2) = 2 \oplus 1 \oplus 0 \oplus 1 \oplus 0 \oplus 1 \oplus 2 = (0 \oplus 0) \oplus (1 \oplus 1) \oplus (2 \oplus 2) \oplus 1 = 1.
