HAL is a multi-disciplinary open access archive for the deposit and dissemination of scientific research documents, whether they are published or not. The documents may come from teaching and research institutions in France or abroad, or from public or private research centers.

L'archive ouverte pluridisciplinaire **HAL**, est destinée au dépôt et à la diffusion de documents scientifiques de niveau recherche, publiés ou non, émanant des établissements d'enseignement et de recherche français ou étrangers, des laboratoires publics ou privés.

LOW MOMENTS OF DIRICHLET SERIES

HUGH L. MONTGOMERY AND GÉRALD TENENBAUM

ABSTRACT. We determine the maximum possible size of the q^{th} moment of a Dirichlet series, for $1 \leq q \leq 2$.

1. INTRODUCTION

In order to bound the mean value of multiplicative functions, Halász [5] introduced a majorant principle which (after a little refining) asserts that if $\lambda_1, \lambda_2, \dots$ are real numbers, if $|a_n| \leq A_n$ for all n , and $\sum_{n \geq 1} A_n < \infty$, then

$$(1.1) \quad \int_{-T}^T \left| \sum_{n \geq 1} a_n e^{i\lambda_n t} \right|^2 dt \leq 3 \int_{-T}^T \left| \sum_{n \geq 1} A_n e^{i\lambda_n t} \right|^2 dt.$$

For a proof of the principle in this form, see Montgomery [8, §7.3]. In Halász's theory, one needs bounds for integrals of the shape

$$(1.2) \quad I(q) = \int_{-1}^1 \left| \sum_p \frac{a_p \log p}{p^{\sigma+it}} \right|^q dt, \quad J(q) = \int_{-1}^1 \left| \sum_{n \geq 1} \frac{b_n}{n^{\sigma+it}} \right|^q dt,$$

when $|a_p| \leq 1$ for all p , and $|b_n| \leq 1$ for all n . From (1.1) it is immediate that

$$I(2) \leq 3 \int_{-1}^1 \left| \sum_{n \geq 2} \frac{\Lambda(n)}{n^{\sigma+it}} \right|^2 dt = 3 \int_{-1}^1 \left| \frac{\zeta'}{\zeta}(\sigma+it) \right|^2 dt \ll \int_{-1}^1 \frac{dt}{|\sigma+it-1|^2} \ll \frac{1}{\sigma-1}$$

uniformly for $1 < \sigma \leq 2$. Similarly, $J(2) \ll 1/(\sigma-1)$ for σ in this range. By applying the majorant principle to the squares of these Dirichlet series we find that $I(4) \ll (\sigma-1)^{-3}$ and $J(4) \ll (\sigma-1)^{-3}$. Hence by Hölder's inequality,

$$(1.3) \quad I(q) \ll (\sigma-1)^{1-q}, \quad J(q) \ll (\sigma-1)^{1-q} \quad (2 \leq q \leq 4),$$

$$(1.4) \quad I(q) \ll (\sigma-1)^{-q/2}, \quad J(q) \ll (\sigma-1)^{-q/2} \quad (1 \leq q \leq 2)$$

uniformly for $1 < \sigma \leq 2$. The estimate (1.3) is best possible, as we see by taking $a_p = 1$ for all p and $b_n = 1$ for all n . For purposes of Halász's theory, it would be helpful if (1.3) would hold also when $1 < q \leq 2$. However, we construct examples that show that the weaker estimate (1.4) is best possible.

Date: November 5, 2014.

2010 *Mathematics Subject Classification.* Primary: 30B50; Secondary: 11Q20, 11N37.

Key words and phrases. Dirichlet series, multiplicative functions.

Theorem 1.1. *Let $I(q)$ and $J(q)$ be defined as in (1.2). There exist numbers a_p with $a_p = \pm 1$ for all p , and b_n with $b_n = \pm 1$ for all n , such that*

$$I(q) \asymp (\sigma - 1)^{-q/2}, \quad J(q) \asymp (\sigma - 1)^{-q/2}$$

uniformly for $1 < \sigma \leq 2$, $1 \leq q \leq 2$.

This is analogous to the situation for Fourier series. For example, if $|b_n| \leq 1$ for $-N \leq n \leq N$ and $e(\vartheta) = e^{2\pi i \vartheta}$, then

$$(1.5) \quad \int_0^1 \left| \sum_{|n| \leq N} b_n e(nx) \right|^q dx \ll N^{q-1}$$

uniformly for $2 \leq q \leq 4$, and

$$(1.6) \quad \int_0^1 \left| \sum_{|n| \leq N} b_n e(nx) \right|^q dx \ll N^{q/2}$$

for $1 \leq q \leq 2$, but there exists a choice of the b_n with $b_n = \pm 1$ for all n such that

$$(1.7) \quad \int_0^1 \left| \sum_{|n| \leq N} b_n e(nx) \right|^q dx \asymp N^{q/2}$$

uniformly for $1 \leq q \leq 2$. Indeed, we use such b_n in our construction.

Antecedents of Halász's majorant principle (1.1) are found in Wiener & Wintner [15] and in Erdős & Fuchs [3]. Logan [6] showed that the constant 3 in (1.1) is best-possible.

2. LEMMAS

We begin with a generalization of a result of H. S. Shapiro [12].

Let the sequence $\{r_n\}_{n=0}^\infty$ be defined by the relations $r_0 = 1$, $r_{2n} = r_n$ and $r_{2n+1} = (-1)^n r_n$. The sequence $\{r_n\}_{n=0}^\infty$ is the classical Rudin–Shapiro sequence. Suppose that the binary expansion of n is $n = \sum_{j \geq 0} e_j(n) 2^j$ where $e_j(n) = 0$ or 1 . A well-known alternative definition is

$$r_n = (-1)^{H(n)}, \text{ where } H(n) := \sum_{j \geq 0} e_j(n) e_{j+1}(n) \quad (n \geq 0).$$

Let $p_m(z)$, $q_m(z)$ denote polynomials defined recursively by the relations $p_0(z) = 1$, $q_0(z) = 1$ and

$$(2.1) \quad \begin{aligned} p_{m+1}(z) &= p_m(z) + z^{2^m} q_m(z) \\ q_{m+1}(z) &= p_m(z) - z^{2^m} q_m(z). \end{aligned}$$

One can easily check that

$$p_m(z) = \sum_{0 \leq n \leq 2^m - 1} r_n z^n \quad (m \geq 0).$$

The Rudin–Shapiro sequence may be generalized by the so-called paper-folding twist. This amounts to introducing a sequence $\{\varepsilon_m\}_{m=0}^\infty \in \{\pm 1\}^\mathbb{N}$ and replacing (2.1) by

$$(2.2) \quad \begin{aligned} p_{m+1}(z) &= p_m(z) + \varepsilon_m z^{2^m} q_m(z) \\ q_{m+1}(z) &= p_m(z) - \varepsilon_m z^{2^m} q_m(z). \end{aligned}$$

We then obtain

$$p_m(z) = \sum_{0 \leq n \leq 2^m - 1} c_n z^n \quad (m = 0, 1, \dots)$$

with

$$(2.3) \quad c_n = r_n \prod_{j \geq 0} \varepsilon_j^{e_j(n)} \quad (n \geq 0),$$

a formula for which we did not find a reference in the literature and which B. Saffari kindly pointed out to us.

Lemma 2.1. *Let the sequence c_m be defined as above. Put*

$$(2.4) \quad P_M(\vartheta) = \sum_{0 \leq m < M} c_m e(m\vartheta).$$

Then

$$|P_M(\vartheta)| \leq (2 + \sqrt{2})\sqrt{M}$$

for all positive integers M and all real ϑ .

Shapiro proved this in the case $c_m = r_m$ ($m \geq 0$) but never published his work. The coefficients r_m were independently discovered by Golay [4]. Rudin [11] published an account of Shapiro's argument in the case $M = 2^k$, but obtained an inferior constant in the general case. The above lemma is proved in [7, théorème 2].

We note in passing that it follows from the proof of theorem 2 of [7] that, given an arbitrary sequence $\{\eta_j\}_{j=0}^\infty \in \{\pm 1\}^\mathbb{N}$, a generalized Rudin–Shapiro sequence may alternatively be written as

$$(2.5) \quad c_m = (-1)^{v_m}$$

where v_m equals 0 or 1 according to whether $\sum_{j \geq 0} \eta_j |e_j(m) - e_{j+1}(m)|$ belongs to $\{0, 1\}$ or to $\{2, 3\}$ modulo 4. In this setting, we recover r_m by selecting $\eta_j = (-1)^j$ ($j \geq 0$). Also, this easily enables retrieving (2.3).

Lemma 2.2. *For $|z| < 1$, let $f(z) = \sum_{m \geq 0} c_m z^m$ where c_m is defined as in (2.3). Then*

$$|f(re(\vartheta))| \leq \frac{2 + \sqrt{2}}{\sqrt{1-r}}.$$

Numerical studies suggest that, at least in the case $c_j = r_j$ ($j \geq 0$),

$$(2.6) \quad \max_{\vartheta} |f(re(\vartheta))| = f(r).$$

Moreover, it is easy to show that, in the above circumstance, $f(r)\sqrt{1-r}$ does not tend to a limit as $r \rightarrow 1^-$. Indeed, it is proved in Brillhart, Erdős and Morton [1] that

$$(2.7) \quad \sum_{m < n} r_m = \sqrt{n} G\left(\frac{\log n}{\log 4}\right) \quad (n \geq 0)$$

where G is 1-periodic and continuous. Moreover, Dumont and Thomas [2] showed that G is nowhere differentiable and Tenenbaum [13] obtained the oscillation result

$$G(x+h) - G(x) = \Omega(\sqrt{h}) \quad (h \geq 0)$$

for any given real number x .

By partial summation it is readily derived from (2.7) that $f(r)\sqrt{1-r}$ oscillates as $r \rightarrow 1-$: indeed, as $y \rightarrow \infty$,

$$(2.8) \quad 2^y f(\exp(-4^{-y}))$$

tends to a 1-periodic, nowhere differentiable function of y .

It is noteworthy that

$$(2.9) \quad \begin{aligned} f(z) &= f(z^2) + f(-z^2), \\ f(-z) &= f(z^2) - f(-z^2). \end{aligned}$$

Kumiko Nishioka [10] showed that $f(z)$ and $f(-z)$ are algebraically independent, and then used these recurrences and Mahler's method to show that if α is algebraic with $0 < |\alpha| < 1$, then $f(\alpha)$ and $f(-\alpha)$ are algebraically independent.

Proof. Clearly

$$\frac{f(re(\vartheta))}{1-r} = \sum_{m \geq 0} P_{m+1}(\vartheta) r^m.$$

Hence by Lemma 2.1 and the triangle inequality it follows that

$$(2.10) \quad \left| \frac{f(re(\vartheta))}{1-r} \right| \leq (2 + \sqrt{2}) \sum_{m \geq 0} \sqrt{m+1} r^m.$$

But

$$(2.11) \quad \sqrt{m+1} \leq \binom{m+1/2}{m}$$

for all non-negative integers m . Hence the right hand side of (2.10) is

$$\leq (2 + \sqrt{2}) \sum_{m \geq 0} \binom{m+1/2}{m} r^m = \frac{2 + \sqrt{2}}{(1-r)^{3/2}},$$

which gives the stated result.

To prove (2.11), let $a_m = \binom{m+1/2}{m} / \sqrt{m+1}$. To show that $a_m \geq 1$, it suffices to note that $a_0 = 1$, and to show that the a_m are increasing. As to this latter point, we observe that

$$\frac{a_m}{a_{m-1}} = \frac{m+1/2}{\sqrt{m(m+1)}} = \frac{2m+1}{\sqrt{(2m+1)^2 - 1}} > 1.$$

□

Lemma 2.3. *Let f be defined as in Lemma 2.2. For each r , $0 < r < 1$, there is a measurable set $A_r \subseteq \mathbb{T}$ with Lebesgue measure $\lambda(A_r) \geq 1/50$, such that*

$$(2.12) \quad |f(re(\vartheta))| \geq \frac{1}{2\sqrt{1-r}}$$

for all $\vartheta \in A_r$.

Proof. Let $B_r = \mathbb{T} \setminus A_r$ be the complementary set of those ϑ on which $|f|$ is small; precisely $|f(re(\vartheta))| < 1/(2\sqrt{1-r})$. By Parseval's identity we know that

$$(2.13) \quad \int_0^1 |f(re(\vartheta))|^2 d\vartheta = \sum_{m \geq 0} r^{2m} = \frac{1}{1-r^2} > \frac{1}{2(1-r)}.$$

By Lemma 2.2, the left hand side above equals

$$\int_{A_r} |f(re(\vartheta))|^2 d\vartheta + \int_{B_r} |f(re(\vartheta))|^2 d\vartheta \leq \frac{(2 + \sqrt{2})^2}{1 - r} \lambda(A_r) + \frac{1 - \lambda(A_r)}{4(1 - r)}.$$

On combining this with (2.13), we find that

$$\frac{1}{4} \leq ((2 + \sqrt{2})^2 - \frac{1}{4}) \lambda(A_r),$$

which gives the stated result. $\square$

Lemma 2.4. *Write $s = \sigma + it$. Then*

$$\sum_{n \leq x} \frac{\Lambda(n)}{n^s} = -\frac{\zeta'}{\zeta}(s) + \frac{x^{1-s}}{1-s} + O\left(\frac{x^{1-\sigma}}{\exp(\sqrt{\log x})}\right)$$

for $x \geq 2$, $1 < \sigma \leq 2$, $-1 \leq t \leq 1$.

This is included in equation (III.5.72) of [14] and is proved by Perron's summation formula (see Montgomery–Vaughan [9, Theorem 5.2] or Tenenbaum [14, corollary II.2.4]) appealing to the classical zero-free region and estimates for $\zeta'(s)/\zeta(s)$ in the zero-free region.

Lemma 2.5. *For $x \geq 2$, $1 < \sigma \leq 2$, and $-1 \leq t \leq 1$, we have*

$$\sum_{n \leq x} \frac{1}{n^s} = \zeta(s) + \frac{x^{1-s}}{1-s} + O\left(\frac{1}{x^\sigma}\right).$$

This is immediate by partial summation; see Montgomery–Vaughan [9, Theorem 1.12] or Tenenbaum [14, theorem II.3.5] for the details.

3. PROOF OF THE THEOREM

In view of the upper bounds of (1.4), it suffices to establish lower bounds. For $I(q)$ we let c_m be defined as in (2.3), and take $a_p := c_m$ for $e^{\pi m} < p < e^{\pi(m+1)}$. Then, for $s = \sigma + it$, $1 < \sigma \leq 2$, $|t| \leq 1$,

$$\begin{aligned} \sum_p \frac{a_p \log p}{p^s} &= \sum_{m \geq 0} c_m \sum_{e^{\pi m} < p < e^{\pi(m+1)}} \frac{\log p}{p^s} \\ (3.1) \quad &= \sum_{m \geq 0} c_m \left(\sum_{e^{\pi m} < n < e^{\pi(m+1)}} \frac{\Lambda(n)}{n^s} + O(e^{\pi m(1-2\sigma)}) \right). \end{aligned}$$

By Lemma 2.4 this is

$$= \sum_{m \geq 0} c_m \left(\frac{e^{\pi(m+1)(1-s)}}{1-s} - \frac{e^{\pi m(1-s)}}{1-s} \right) + O\left(\sum_{m \geq 0} \frac{e^{\pi m(1-\sigma)}}{\exp(c\sqrt{m})} \right) + O(1).$$

Here the first error term is also $O(1)$, uniformly for $\sigma \geq 1$. The main term is

$$(3.2) \quad F(s) f(e^{\pi(1-s)})$$

where f is defined in Lemma 2.2, and

$$(3.3) \quad F(s) = \frac{e^{\pi(1-s)} - 1}{1-s}.$$

The zeros of this entire function are the numbers $1+2im$ where m runs over non-zero integers. Thus $|F(s)|$ is bounded away from 0 uniformly on the rectangle $1 \leq \sigma \leq 2$,

$-1 \leq t \leq 1$. With a little computation one can in fact show that the minimum of $|F(s)|$ in this rectangle is $|F(2 \pm i)| \approx 0.73766$. By Lemma 2.3 it follows that if σ is fixed, $1 < \sigma \leq 2$, then

$$\left| \sum_p \frac{a_p \log p}{p^{\sigma+it}} \right| \gg \frac{1}{\sqrt{1 - e^{\pi(\sigma-1)}}} \asymp \frac{1}{\sqrt{\sigma-1}}$$

when $t/2 \in A_{e^{\pi(\sigma-1)}}$, i.e. on a subset of $-1 \leq t \leq 1$ of measure $> 1/25$. Hence $I(q) \gg (\sigma-1)^{-q/2}$.

The proof for $J(q)$ is the same, except that now the passage from $\log p$ to $\Lambda(n)$ in (3.1) is unnecessary, and instead of Lemma 2.4 we use Lemma 2.5, in which the error term is smaller.
