Abstract—This paper studies the effect of ferrite beads on the audio quality of Class-D audio amplifiers. This latter is a switching circuit which creates high frequency harmonics. Generally, a filter is used at the amplifier output for the sake of electromagnetic compatibility (EMC). So often, in integrated solutions, this filter contains ferrite beads which are magnetic components and present nonlinear behavior. Time domain measurements and their equivalence in frequency domain are presented. Total Harmonic Distortion (THD) measurements according to the audio signal frequency and amplitude are exposed and discussed. It is shown that ferrite beads introduce up to 30 dB of additional THD which prove the negative effect of the ferrite bead on the amplifier audio quality.

I. INTRODUCTION

The work exposed in this paper is dedicated to the audio systems of embedded applications. For such devices, the energy is provided by a battery and is then limited. Therefore, for a longer battery life, managing the energy distributed among all parts of this device, in the most efficient way, is a need. Concerning specifically the audio application, nowadays Class-D amplifiers combine high power efficiency and low audio distortion. Its power efficiency can reach 95 % while for other classes, the power efficiency cannot exceed 75 % [1]. Mainly for this reason, the Class-D is widely used in hands free applications [2]. The Class-D amplifiers, having a similar topology as a buck converter, are switching circuits controlled by a pulse width modulation (PWM) as shown in Fig. 1. The audio signal is compared to a triangular signal with higher frequency which can be in the range of [48 kHz-1 MHz]. This generates the PWM signal that controls the switching

power stage. Fig. 2 shows the amplifier output spectrum for a given audio signal. The audio signal is a 10 kHz sinusoidal wave, the fundamental switching frequency is 420 kHz and the harmonics are spread all over the frequency band [3]–[5].

This amplifier can therefore, be a source of electromagnetic interference (EMI) and then disturb surrounding electronic devices. Thus, an EMI filter is required to eliminate the high frequency harmonics. In mobile phones and integrated applications, ferrite beads are used in EMI filters for their impedance characteristics and their broadband effect [6]. The ferrite bead impedance behavior allows a wide range filtering effect compared to an inductor. In addition, the ferrite bead dissipates the high frequency disturbance into heat due to its resistive behavior at high frequencies [6].

By neglecting the nonlinear behavior of magnetic materials, the impedance of the ferrite bead can be resumed to a

linear equation. Therefore, the ferrite bead low signal level impedance behavior with respect to the frequency has already been defined in the literature and used in many types of simulation [7]–[9]. These model are in general obtained by impedance fitting using the impedance measurement on the component. This lead to the most common ferrite bead models (see Fig. 3) which are composed by linear resistors, inductors and capacitors. Often they are provided by the ferrite bead suppliers as well.

However, a ferrite bead is made of magnetic materials, thus, it has nonlinear effects due to the hysteresis loop and the magnetic saturation [10]. In audio applications, nonlinear behavior has an impact on the signal audio quality [11]. The ferrite bead can, thus, contribute to deteriorate the signal audio quality provided by the power amplifier.

Since the aforementioned model do not take into account the ferrite bead nonlinearities, no simulations can be done that study the effect of an EMI filter including a ferrite bead on the audio reproduction chain. In addition, by the authors best knowledge, no publications have been found that study such phenomenon. Therefore, this paper presents some experimental measurements in order to expose the ferrite bead behavior in the audio band and quantify these effects on an audio amplifier's performance.

Fig. 4. Circuit schematic.

In section II, time domain measurements of the voltage across the ferrite bead are exposed to show the nonlinear characteristics of the ferrite bead. In section III, the equivalence of time domain measurements in the frequency domain are shown to evaluate their effect in the audio band. Section IV exposes total harmonic distortion (THD) measurements with respect to the signal amplitude level and to the frequency. Finally, section V concludes the paper.

II. TIME DOMAIN MEASUREMENTS

This section shows time domain measurements on a simplified circuit containing a ferrite bead.

A. Bench description

Fig. 4 shows the circuit schematic used to measure the voltage delivered by the power amplifier (V_{in}) and the voltage across the load (i.e., loudspeaker) (V_{out}). The circuit contains a ferrite bead in series with a linear amplifier (voltage gain 0 dB) and a load of $8\ \Omega$ (similar to the DC resistance of the loudspeaker). A ferrite bead with a rated current of 50 mA, a DC resistor of $1.5\ \Omega$ and $0.6\text{ mm} \times 0.3\text{ mm}$ dimensions. A linear amplifier is used rather than a class-D amplifier. This choice allows to remove the high frequencies effect of a PWM class-D signal and focus only on the effect of a ferrite bead in the audio band. The measurements were made using a 12-bit digital oscilloscope which is represented by the measuring instrument in Fig. 4.

To avoid increasing the temperature of the ferrite bead and therefore changing its internal resistance, the signal applied at the input of the amplifier was burst pulses of five periods of a 1 kHz sinusoidal signal. Pulses were separated by a delay of one second. The voltage across the ferrite bead is then the difference between V_{in} and V_{out} .

B. Measurement

Fig. 5 shows the measurement on V_{in} and V_{out} in the time domain. Fig. 5 shows as well a zoom on both voltages near to

their zero level. It can be seen that voltage measured before the ferrite bead V_{in} keeps its sinusoidal nature. However, the voltage measured after the ferrite bead, presents some nonlinear behavior near to zero. According to (??), the voltage across the ferrite bead is computed and shown in Fig. 6.

As can be seen in Fig. 6, peaks appear when the signal passes through 0 V. This can be explained by considering the relationship of the voltage across the ferrite bead to the magnetic flux density (1) and the relationship of the ferrite bead current to the magnetic field (2)

$$B(t) = \frac{1}{NS} \int [v_f(t) - R_{DC}i_f(t)]dt \quad (1)$$

$$H(t) = \frac{N}{l} i_f(t) \quad (2)$$

where v_f is the ferrite bead voltage, i_f is the ferrite bead current, N the turn number of the coil, l the effective length,

Fig. 7. Magnetic hysteresis loop.

Fig. 8. Effect of the ferrite bead in the audio frequency band.

S the section area of the magnetic material, B the flux density, H the magnetic field and t is the time. A fast variation of B , which means a high slope in Fig. 7, happens at H zero crossing and therefore at the i zero crossing (since i and H are proportional). This induces the fast variation of v_f which creates voltage peaks at the zero crossing parts denoted by P_1 and P_2 in Fig. 6.

III. FREQUENCY DOMAIN ANALYSIS

The Fast Fourier Transform (FFT) was applied on V_{in} and V_{out} to transform the time domain signals into the frequency domain. Fig. 8 shows the frequency domain results of both voltages.

As seen in Fig. 8, the voltage across the load V_{out} is affected by the nonlinear behavior of the ferrite bead. The impact appears as odd harmonics in the audio band which can be

explained by the fact that the hysteresis loop is symmetric around zero [12].

By definition, the increase of the harmonics implies an increase of the THD. This latter is the ratio of the harmonic power sum over the fundamental power for a given signal. It is used to quantify the signal linearity. A low or a high THD would mean respectively a good or a bad linearity of the signal. In the audio applications, the THD is used to evaluate the efficiency of a given system to reconstitute the original audio signal. In this case, only the harmonics in the audio frequency band ($[20\text{ Hz} - 20\text{ kHz}]$) are taken into account. The next section will therefore show THD measurements with respect to the signal frequency and to the signal amplitude levels.

IV. THD MEASUREMENTS

In this section, the total harmonic distortion is measured to quantify the impact of the ferrite bead on the signal audio quality.

The THD was measured using an audio analyzer to study the effect of the ferrite bead on the signal linearity. Thus, measurement for different signal amplitudes and signal frequencies have been made. Note that, each measurement point uses 9 harmonics for THD measurements.

The circuit schematic used to measure the THD is the same as the one described in Fig. 5. The only differences are: first, the measuring instrument is an audio analyzer instead of an oscilloscope, second, a ferrite bead having a rated current of 2 A and a DC resistor of $50\text{ m}\Omega$ is used. This ferrite bead is chosen for these measurement because generally, for industrial applications, ferrite beads with high rated current and low DC resistors are used. Thus, it is possible to quantify the THD in real use case.

Fig. 9 and Fig. 10 show the THD measurements according to the signal amplitude and signal frequency respectively. In Fig. 9, the measurements were done using a 1 kHz sinusoidal signal, sweeping the amplitude level from 1 mV to 7 V . In Fig. 10, the measurements were done using a 200 mV sinusoidal signal with a frequency sweep from 20 Hz to 10 kHz . Note that Fig. 10 shows measurements up to 10 kHz only, since all the harmonics become out of band when the signal frequency exceeds 10 kHz .

In Fig. 9 and Fig. 10, THD_{Gen} is the THD of the original signal delivered by the generator. $THD_{OpenCircuit}$ is the THD at the output of the amplifier when it's operating in open circuit (no current is delivered). THD_{in} and THD_{out} are respectively the THD for V_{in} and V_{out} (see Fig. 4). THD_{in} represents the THD of the linear amplifier when delivering a current to the load. THD_{out} represents the THD across the load voltage. Therefore, the difference between THD_{in} and THD_{out} is due to the ferrite bead.

As can be seen from Fig. 9, the ferrite bead deteriorates the signal THD in the amplitude range $[10\text{ mV} - 7\text{ V}]$. Ferrite beads have a negative impact on the audio signals even though the component current in the range of $[1\text{ mA} - 737\text{ mA}]$ is lower than the component rated current which is 2 A . However, below 10 mV the amplifier output noise does not allow any

comparison. Moreover, Fig. 10 shows that the ferrite bead increases the THD on the entire frequency range. Note that, beyond 6.5 kHz the THD measurements decrease suddenly. This is because some of the odd harmonics are already out of the audio band.

As a result, the ferrite bead increases the THD of the signal delivered by the amplifier at all frequencies and a wide range of signal levels. The deterioration caused by the ferrite bead can reach -35 dB . Note that, -40 dB of THD level can be distinguished by the human ear. Thus, the ferrite bead reduces the audio quality of the amplifier due to its nonlinear effect in the audio band.

V. CONCLUSION

This paper showed that ferrite beads used for EMI suppression in Class-D amplifier systems, have a non-negligible effect on the amplifier audio quality. In the time domain, the ferrite

bead nonlinear behavior is seen as peaks apparition at voltage zero crossing. This can be translated to the frequency domain by an increase of the odd harmonics in the audio frequency band.

Furthermore, the THD measurements showed the impact of the ferrite bead on the audio quality for all the tested frequencies and a wide range of signal amplitudes. The THD measurements and FFT calculations proved, therefore, the significant impact of these non-linearities on the audio performance.

This paper highlights the need of a model taking into account the ferrite bead non-linear behavior, to help the designers choose their optimal ferrite bead.
