Iron/Caffeine as a Catalytic System for Microwave-Promoted Benzamide Formation

Xavier Bantreil,*[a] Pauline Navals,[a] Jean Martinez,[a] and Frédéric Lamaty*[a]

Dedicated to Professor Max Malacria on the occasion of his 65th birthday

Keywords: Homogeneous catalysis / Oxidation / Microwave chemistry / Amides / Iron

The amide bond is an essential unit in many drugs and polymers. The catalyzed oxidation of alcohols and amines is an effective method to form amides with limited undesired waste. Herein, we demonstrate the beneficial effect of microwave activation for this reaction. The benzamides were directly formed from alcohols and amine hydrochloride salts in short reaction times with yields up to 84% and TOFs (turnover frequencies) up to 33.6 h⁻¹. Among the examined transition metals, only nontoxic and inexpensive FeCl₂·4H₂O together with caffeine as a stabilizing ligand provided a uniquely efficient catalytic system for the transformation. Natural sources of caffeine were also evaluated under the amidation conditions.

Introduction

The amide functional group is present in numerous highly valuable compounds.[1] Because of its distinct planar structure and polarity, the amide group participates in interactions (e.g., hydrogen bonding or electrostatic interactions) that are closely related to the activity of a compound. Many natural products, peptides, and proteins, as well as non-natural drugs and polymers contain an amide group. Several structures of pharmaceutical compounds that have an amide moiety are depicted in Figure 1. In most cases, the amide functionality in those molecules was introduced by a carboxylic acid that was activated by using a stoichiometric amount of an acylating or coupling agent. Although a wide variety of coupling agents have been developed,[2] most methods generate an excess amount of undesired waste.

To develop new methods to efficiently form amide bonds and reduce the impact on the environment, chemists have turned their attention to catalysis.[3] Among the most recent techniques, boronic acid catalyzed couplings[4] and metal-catalyzed reactions[5] have attracted much attention. In particular, since the pioneering works on ruthenium[6] and rhodium chemistry,[7] the oxidative coupling of alcohols and amines into the corresponding amides has been widely studied. Much effort has been devoted to finding conditions that employ less expensive and less toxic transition metals than Ru and Rh. In this context, we recently demonstrated that amides could be directly obtained from benzyl alcohol and amines in the presence of tert-butyl hydroperoxide (TBHP) as the oxidant and by using copper as an inexpensive and nontoxic catalyst.[8] Since then, copper nanoparticles,[9] zinc,[10] and iron[11] have been proven to catalyze this domino reaction efficiently. One major improvement of these procedures would be to combine the efficiency of the catalytic system with an activation method such as microwaves. Indeed, although microwave activation has been widely studied and efficiently used in organic synthesis as well as organometallic chemistry,[12] its beneficial

Figure 1. Structure of pharmaceutical compounds that feature an amide bond.
effects in the oxidation of alcohols into amides have never been witnessed.\[^{13}\] Herein, among the transition metals described above, we demonstrated that only iron in combination with a suitable caffeine ligand was able to promote the efficient formation of benzamide upon microwave activation.

**Results and Discussion**

We began our study of microwave activation by directly adapting the conditions from our last report about benzamide formation.\[^{11c}\] However, under those reaction conditions, the use of CaCO\(_3\) as the base provoked a fast release of CO\(_2\), which resulted in a sudden and dangerous rise of pressure in the sealed microwave reactor. Such behavior prompted us to turn our attention toward other bases that would be able to mimic the reactivity of calcium carbonate and slowly liberate the free amine in the reaction mixture.\[^{14}\] To modulate the equilibrium for the deprotonation of the (\(\alpha\))-methylbenzylamine hydrochloride salt (p\(K_a\) = 9.83\[^{15}\]), a screening of organic bases with different p\(K_a\) values was performed (see Figure 2). The use of pyridine (p\(K_a\) = 5.14)\[^{16}\] afforded the formation of amide 3aa in 55\% isolated yield. By lowering the p\(K_a\) value of the base to between 2.84 (3-chloropyridine) and 0.61 (caffeine), thereby reducing the formation of the free amine in the reaction mixture, we observed an increase in the yield to 71\%. However, urea and 2-fluoropyridine, with very low p\(K_a\) values, proved inefficient. Among the three optimal bases, caffeine, which is less toxic and less expensive, was selected for further studies.

\[^{[a]}\] Reagents and conditions: 2a (0.5 mmol), 1a (0.75 mmol), caffeine, TBHP (70\% in H\(_2\)O, 3.0 mmol), catalyst, CH\(_3\)CN (1 mL), 130 °C, MW, 30 min. \[^{[b]}\] Isolated yield. \[^{[c]}\] Not determined. \[^{[d]}\] 1a (2 equiv.) was used. \[^{[e]}\] Under traditional heating for 4 h at 80 °C.
An exemplification of this method was then performed by using the iron/caffeine/microwave activation combination (see Scheme 2). Benzamides 3aa, 3ab, 3ac, 3ad, and 3ae, which feature oxidizable benzylic positions, were isolated in 48–81% yield. Remarkably, the hydroxy group of phenyl glycinol 2c remained unchanged during the reaction, which proved the selectivity of the conditions towards the benzylic alcohols.

In addition, no epimerization at the stereogenic centers was observed by using the microwave-promoted conditions. Amide 3aa was also obtained in 84% yield by using (α)-methylbenzylamine and concentrated HCl to preform 2a in situ, which proves that this procedure could be applied to highly hygroscopic and difficult to handle hydrochloride salts. Alkylamines that contained the butyl, cyclohexyl, or tert-butyl group (i.e., 2f, 2g, and 2h) gave the corresponding amides in 71, 73, and 77% yield, respectively. The beneficial effect of the use of a microwave is highlighted by this last result, as the corresponding yield of 3ah under traditional conditions was only 59%. Benzoylated morpholine 3ai, dibenzylamine 3aj, and sarcosine methyl ester 3ak were isolated in 64–69% yield. Finally, the aromatic moiety of hydroxy partner 1 was varied and submitted to a reaction with 2a. A chloro substituent did not have an impact on the reaction (e.g., 3ba, 73% yield; 3da, 71% yield), whereas a nitro and methoxy group strongly decreased the yield (e.g., 3ca, 3ea, and 3fa, 52–59% yield). Finally, 2-chlorobenzyl alcohol 1g, which is more hindered than 1b and 1d, underwent the reaction to yield amide 3ga in 49% yield. It is important to stress that the TOF values that were obtained as a result of microwave activation (TOF 14.7–33.6 h⁻¹) are significantly higher than those of other reports (TOF <11 h⁻¹).

Finally, we envisioned that this reaction was possible by using directly natural sources of caffeine, coffee beans, or tea leaves. Indeed, it has already been shown that the formation of Ag, Pd, and Fe nanoparticles with caffeine/polyphehols is possible by using coffee or tea extract. Thus, Arabica and Robusta coffee beans were evaluated in varying quantities along with water or chloroform as an additive to ensure good extraction of the caffeine (see Table 2, Entries 1–6). However, the yield of 3aa could not exceed 58%. Using crushed beans did not improve the reaction results (see Table 2, Entry 4). Similar results were obtained with tea leaves (see Table 2, Entry 7). As shown previously (see Table 1, Entry 13), the reaction in the absence of caffeine afforded a 66% yield of 3aa. These data demonstrate that, apart from caffeine, other organic compounds that are contained in the beans might be extracted during the reaction process, and those undesired compounds might react and, hence, consume the reagents or poison the catalyst in the reaction media.

[a] Reagents and conditions: 2a (0.5 mmol), 1a (1.0 mmol), TBHP (3.0 mmol), FeCl₃·4H₂O (0.025 mmol), CH₃CN (1 mL), 130 °C. [b] The volume of the solvent was 1.5 mL.
Conclusions

In summary, we demonstrated that the unique catalytic system that involves iron(II) and caffeine as a stabilizing ligand was compatible with microwave activation to efficiently perform a domino benzamide formation with TOFs up to 33.6 h⁻¹. In only 30 to 45 min, a variety of benzamides were formed directly from alcohols and amine hydrochlorides in yields up to 84%. The importance of microwave irradiation was confirmed when a low yield was obtained by traditional heating. In addition, it was shown that amine hydrochlorides could be formed in situ directly from the corresponding amine and concentrated HCl, thus allowing the use of a wide range of amines, the hydrochloride salts of which would be hygroscopic and difficult to handle.

Experimental Section

General Methods: All reagents were purchased from chemical suppliers and used without further purification. The 1H and 13C NMR spectroscopic data were recorded with Bruker Avance DPX 200 MHz and Bruker Avance AM 300 MHz spectrometers. The chemical shifts were calibrated by using the solvent signals as internal references (CHCl3, δ = 7.26 ppm for 1H NMR and CDCl3, δ = 77.16 ppm for 13C NMR; [D6]DMSO, δ = 2.50 ppm for 1H NMR and [D6]DMSO, δ = 39.52 ppm for 13C NMR). Analytical high performance liquid chromatography was performed on a Waters Millenium 717 that was equipped with an autosampler and had a variable wavelength diode detector. A Chromolith RP18 column (50 x 4.6 mm) was employed, and a flow rate of 5 mL min⁻¹ was used with a linear gradient of CH3CN in water of 0–100% (0.1% TFA) over 4.5 min. Flash chromatography was performed by using prepacked silica columns on a Biotage® IsoleraTM Four system. Reactions were performed in a Biotage® Initiator™ microwave synthesizer. The temperature was measured with an IR sensor on the outer surface of the reaction vial. The general procedures below for the iron-catalyzed synthesis of the amides under microwave irradiation involve the reaction of (α)-methylbenzylamine·HCl (2a) and benzyl alcohol (1a).

Procedure for Amide Formation by Using a Preformed Amine Hydrochloride: In a microwave reactor (0.5–2.0 mL) were added (α)-methylbenzylamine (64 μL, 0.5 mmol, 1 equiv.), CH3CN (1 mL) and then HCl (37% solution, 42 μL, 0.5 mmol, 1 equiv.) were added at 0 °C until a white precipitate ([α]-methylbenzylamine·HCl) appeared. FeCl2·4H2O (5.0 mg, 0.025 mmol, 5 mol-%), caffeine (9.7 mg, 0.05 mmol, 10 mol-%), benzyl alcohol (104 μL, 1.0 mmol, 2 equiv.), and tert-butyl hydroperoxide (70% in H2O, 140 μL, 2 equiv.) were then added. After stirring at 130 °C for 10 min under microwave irradiation, additional tert-butyl hydroperoxide (70% in H2O, 2 equiv.) was added, and the mixture was stirred at 130 °C for 10 min. After cooling to room temp., HCl 1 N solution, (5 mL) and AcOEt (5 mL) were added, and the mixture was extracted with AcOEt (2 x 5 mL). The combined organic phases were washed with saturated aqueous NaHCO3 solution (10 mL) and brine (10 mL), dried with magnesium sulfate, and concentrated under reduced pressure. The crude mixture was purified by chromatography on a silica gel column (cyclohexane/ethyl acetate).

Characterization of Compounds

(α)-N-(α-Methylbenzyl)benzamide (3aa):[23] 1H NMR (200 MHz, CDCl3): δ = 7.90–7.67 (m, 2 H), 7.55–7.18 (m, 8 H), 6.60 (d, J = 6.9 Hz, 1 H), 5.33 (p, J = 7.0 Hz, 1 H), 1.59 (d, J = 6.9 Hz, 3 H) ppm. 13C NMR (75 MHz, CDCl3): δ = 166.7, 143.3, 134.6, 131.4, 128.7, 128.5, 127.3, 127.1, 126.3, 49.2, 21.8 ppm.

N-Benzylazobenzamide (3ab):[22] 1H NMR (200 MHz, CDCl3): δ = 7.89–7.70 (m, 2 H), 7.57–7.27 (m, 8 H), 6.67 (s, J = 1.1 Hz), 4.62 (d, J = 5.7 Hz, 2 H) ppm. 13C NMR (75 MHz, CDCl3): δ = 167.5, 138.3, 134.5, 131.6, 128.9, 128.7, 128.0, 127.7, 127.1, 44.2 ppm.

N-(methyl)phenylglycinol (3ac):[23] 1H NMR (300 MHz, [D6]DMSO): δ = 8.70 (d, J = 8.0 Hz, 1 H), 7.91 (d, J = 6.8 Hz, 2 H), 7.62–7.43 (m, 3 H), 7.40 (d, J = 7.2 Hz, 2 H), 7.32 (t, J = 7.4 Hz, 2 H), 7.23 (t, J = 7.1 Hz, 1 H), 5.09 (dd, J = 13.6, 7.9 Hz, 1 H), 4.94 (s, J = 1.1 Hz), 3.83–3.57 (m, 2 H) ppm. 13C NMR (75 MHz, [D6]DMSO): δ = 166.2, 141.4, 134.7, 131.2, 128.2, 128.1, 127.4, 127.0, 126.8, 64.6, 56.0 ppm.

N-(methyl)phenylalaninol (3ad):[24] 1H NMR (300 MHz, CDCl3): δ = 7.72 (d, J = 6.8 Hz, 2 H), 7.63–7.11 (m, 7 H), 6.94 (s, J = 1.1 Hz), 6.02 (s, 1 H), 5.56 (s, 1 H), 4.91 (dd, J = 13.9, 7.1 Hz, 1 H), 3.21 (qd, J = 13.6, 6.8 Hz, 2 H) ppm. 13C NMR (75 MHz, CDCl3): δ = 173.1, 167.4, 136.7, 133.8, 132.1, 129.5, 129.0, 128.8, 127.4, 127.2, 54.6, 38.5 ppm.

N-(methyl)phenylalanylnol (3ae):[25] 1H NMR (200 MHz, CDCl3): δ = 7.70–7.61 (m, 2 H), 7.48–7.06 (m, 8 H), 6.60 (d, J = 7.2 Hz, 1 H), 4.88 (dt, J = 7.4, 5.8 Hz, 1 H), 3.15 (d, J = 5.8 Hz, 2 H), 1.35 (s, 9 H) ppm. 13C NMR (75 MHz, CDCl3): δ = 170.8, 166.8, 136.3, 134.2, 131.7, 129.7, 128.6, 128.5, 127.1, 82.6, 54.0, 38.1, 28.1 ppm.

N-(methyl)butytalaninol (3af):[25] 1H NMR (200 MHz, CDCl3): δ = 7.81–7.68 (m, 2 H), 7.52–7.29 (m, 3 H), 6.45 (s, 1 H), 3.51–3.32 (m, 2 H), 1.68–1.46 (m, 2 H), 1.47–1.27 (m, 2 H), 0.92 (t, J = 7.2 Hz, 3 H) ppm. 13C NMR (75 MHz, CDCl3): δ = 167.7, 134.9, 131.3, 128.5, 127.0, 39.9, 31.8, 20.2, 13.8 ppm.

N-cyclohexylalaninol (3ag):[26] 1H NMR (200 MHz, CDCl3): δ = 7.87–7.61 (m, 2 H), 7.55–7.29 (m, 3 H), 6.17 (s, 1 H), 4.12–3.78 (m, 1 H), 2.02–1.74 (m, 2 H), 1.68–1.60 (m, 3 H), 1.52–1.05 (m, 5 H) ppm. 13C NMR (75 MHz, CDCl3): δ = 166.8, 135.2, 131.3, 128.5, 120.0, 48.3, 33.3, 25.6, 25.0 ppm.

N-(methyl)butylbenzamide (3ah):[27] 1H NMR (200 MHz, CDCl3): δ = 7.87–7.58 (m, 2 H), 7.58–7.28 (m, 3 H), 5.97 (s, 1 H), 1.46 (s, 9 H) ppm. 13C NMR (75 MHz, CDCl3): δ = 167.0, 136.0, 131.1, 128.5, 126.8, 51.6, 28.9 ppm.
N-Benzylimorpholine (3ai)[28] 1H NMR (200 MHz, CDCl₃); δ = 7.39 (s, 5 H), 4.18–3.09 (m, 8 H) ppm. 13C NMR (75 MHz, CDCl₃); δ = 170.5, 135.3, 129.9, 128.6, 127.1, 66.9 ppm.

N,N-Dibenzyldiamide (3aj)[28] 1H NMR (200 MHz, CDCl₃); δ = 7.58–7.44 (m, 2 H), 7.44–7.28 (m, 11 H), 7.17 (s, 2 H), 4.71 (s, 2 H), 4.42 (s, 2 H) ppm. 13C NMR (75 MHz, CDCl₃); δ = 172.3, 137.0, 136.5, 136.2, 129.7, 128.9, 128.6, 128.5, 127.7, 127.1, 126.8, 51.6, 46.9 ppm.

N-Benzoylsarcosine Methyl Ester (3ak)[29] 1H NMR (200 MHz, CDCl₃); rotamers, 65:35; δ = 7.55–7.29 (m, 5 H), 4.25 (s, 2 H), 65%), 3.97 (s, 2 H, 35%), 3.75 (s, 3 H, 30%), 3.01 (s, 3 H, 65%) ppm. 13C NMR (75 MHz, CDCl₃); δ = 172.1, 169.6, 135.5, 129.9, 128.7, 128.4, 127.2, 126.6, 53.2, 52.4, 52.2, 49.1, 38.7, 34.4 ppm.

(±)-(p-Chlorobenzoyl)-α-methylbenzylamine (3ab)[30] 1H NMR (200 MHz, CDCl₃); δ = 7.77–7.58 (m, 2 H), 7.45–7.27 (m, 7 H), 6.74 (d, J = 7.4 Hz, 1 H), 5.28 (p, J = 7.0 Hz, 1 H), 1.57 (d, J = 6.9 Hz, 3 H) ppm. 13C NMR (75 MHz, CDCl₃); δ = 165.7, 143.1, 137.7, 133.0, 128.8, 128.8, 128.6, 127.6, 126.3, 49.5, 21.8 ppm.

(±)-(p-Nitrobenzoyl)-α-methylbenzylamine (3ac)[30] 1H NMR (200 MHz, CDCl₃); δ = 8.8–7.21–8.3 (m, 2 H), 7.94–7.83 (m, 2 H), 7.41–7.27 (m, 5 H), 6.77 (d, J = 7.4 Hz, 1 H), 5.30 (p, J = 7.0 Hz, 1 H), 1.61 (d, J = 6.9 Hz, 3 H) ppm. 13C NMR (75 MHz, CDCl₃); δ = 164.8, 149.5, 142.7, 140.2, 128.9, 128.3, 127.8, 126.3, 123.7, 49.8, 21.7 ppm.

(±)-(m-Chlorobenzoyl)-α-methylbenzylamine (3ad)[30] 1H NMR (200 MHz, CDCl₃); δ = 7.74 (d, J = 1.6 Hz, 1 H), 7.62 (d, J = 7.6 Hz, 1 H), 7.49–7.17 (m, 7 H), 6.72 (s, 1 H), 5.29 (p, J = 7.0 Hz, 1 H), 1.58 (d, J = 6.9 Hz, 3 H) ppm. 13C NMR (75 MHz, CDCl₃); δ = 165.5, 143.0, 136.5, 134.7, 131.5, 129.9, 128.8, 127.6, 127.4, 126.3, 125.2, 49.5, 21.7 ppm.

(±)-(m-Methoxybenzoyl)-α-methylbenzylamine (3ae)[30] 1H NMR (200 MHz, CDCl₃); δ = 7.50–7.15 (m, 8 H), 7.15–6.76 (m, 1 H), 6.57 (d, J = 7.4 Hz, 1 H), 5.31 (p, J = 7.0 Hz, 1 H), 3.80 (s, 3 H), 1.59 (d, J = 6.9 Hz, 3 H) ppm. 13C NMR (75 MHz, CDCl₃); δ = 166.6, 159.9, 143.3, 136.1, 129.6, 128.8, 127.5, 126.3, 113.8, 111.7, 112.5, 55.5, 49.4, 21.8 ppm.

(±)-(m-Nitrobenzoyl)-α-methylbenzylamine (3af)[30] 1H NMR (200 MHz, CDCl₃); δ = 8.57 (t, J = 1.9 Hz, 1 H), 8.29 (ddd, J = 8.2, 2.2, 1.1 Hz, 1 H), 8.22–8.05 (m, 1 H), 7.57 (t, J = 8.0 Hz, 1 H), 7.43–7.23 (m, 5 H), 7.02 (d, J = 7.6 Hz, 1 H), 5.31 (p, J = 7.0 Hz, 1 H), 1.61 (d, J = 6.9 Hz, 3 H) ppm. 13C NMR (75 MHz, CDCl₃); δ = 164.4, 148.2, 142.7, 136.2, 133.5, 129.9, 128.9, 127.7, 127.6, 126.4, 126.1, 121.9, 49.9, 21.7 ppm.

(±)-(N-Chloroazobenzoyl)-α-methylbenzylamine (3ag)[30] 1H NMR (200 MHz, CDCl₃); δ = 7.76–7.55 (m, 5 H), 7.55–7.27 (m, 8 H), 6.51 (d, J = 5.2 Hz, 1 H), 5.34 (p, J = 7.0 Hz, 1 H), 1.61 (d, J = 6.9 Hz, 3 H) ppm. 13C NMR (75 MHz, CDCl₃); δ = 165.7, 142.9, 135.2, 131.4, 130.7, 130.4, 130.3, 128.8, 127.6, 127.2, 126.4, 49.7, 21.9 ppm.

Supporting Information (see footnote on the first page of this article): 1H and 13C NMR spectra of all compounds and chiral HPLC analysis.

Acknowledgments

This work was realized thanks to the funding from the Centre National de la Recherche Scientifique (CNRS) and the Université Montpellier 2.
