Keywords: Gradient Schemes, incompressible steady Navier-Stokes problem, Crouzeix-Raviart Scheme, Taylor-Hood scheme, MAC scheme.

Abstract. We apply the Gradient Schemes framework to the approximation of the incompressible steady Navier-Stokes problem. We show that some classical schemes (Crouzeix-Raviart, conforming Taylor-Hood and MAC) enter into this framework.

1 Introduction

The gradient scheme framework has been shown to apply to linear and non-linear elliptic and parabolic problems in [8, 4, 5, 7]. This framework has the benefit of providing common convergence and error estimates results which hold for a wide variety of numerical methods (finite element methods, non-conforming and mixed finite element methods, hybrid and mixed mimetic fi-
nite difference methods...). Checking a minimal set of properties for a given numerical method suffices to prove that it belongs to the gradient schemes framework, and therefore that it is convergent on the aforementioned problem. The aim of this paper is to propose one extension of this framework to the incompressible steady Navier-Stokes problem:

\[
\begin{align*}
\eta \bar{u} - \nu \Delta \bar{u} + (\bar{u} \cdot \nabla) \bar{u} + \nabla p &= f - \text{div}(G) \quad \text{in } \Omega \\
\text{div } \bar{u} &= 0 \quad \text{in } \Omega \\
\bar{u} &= 0 \quad \text{on } \partial \Omega
\end{align*}
\] (1)

where \( \eta \geq 0, \nu > 0 \) is the coefficient of kinematic viscosity, \( \bar{u} \) represents the velocity field, \( p \) is the pressure and \( \Omega \) is an open bounded Lipschitz domain of \( \mathbb{R}^d \) (\( 1 \leq d \leq 3 \)), \( f \in L^2(\Omega) \) and \( G \in L^2(\Omega)^d \).

In the following, if \( F \) is a vector space we denote by \( F^d \) the space \( F \times \cdots \times F \). Thus, \( L^2(\Omega) = L^2(\Omega)^d \) and \( H^1_0(\Omega) = H^1_0(\Omega)^d \), and we define the spaces

\[ E(\Omega) = \{ \bar{v} \in H^1_0(\Omega), \text{div} \bar{v} = 0 \}, \]

and

\[ L^2_0(\Omega) = \{ \bar{v} \in L^2(\Omega), \int_{\Omega} \bar{v}(x) dx = 0 \}, \]

**Definition 1.1 (Weak solution to the incompressible steady Navier-Stokes problem)**

Under Hypotheses (2), \( (\bar{u}, p) \) is a weak solution to (1) if

\[
\begin{align*}
\bar{v} \in H^1_0(\Omega), \bar{p} \in L^2_0(\Omega), \\
\eta \int_{\Omega} \bar{u} \cdot \bar{v} dx + \nu \int_{\Omega} \nabla \bar{u} : \nabla \bar{v} dx + b(\bar{u}, \bar{v}) \\
- \int_{\Omega} \bar{p} \text{div} \bar{v} dx &= \int_{\Omega} (f \cdot \bar{v} + G : \nabla \bar{v}) dx, \quad \forall \bar{v} \in H^1_0(\Omega), \\
\int_{\Omega} q \text{div} \bar{u} dx &= 0, \quad \forall q \in L^2_0(\Omega),
\end{align*}
\] (3)

where \( \cdot \) is the dot product on \( \mathbb{R}^d \), if \( \tau = (\tau^{i,j})_{i,j=1,...,d} \in \mathbb{R}^{d \times d} \) and \( \sigma = (\sigma^{i,j})_{i,j=1,...,d} \in \mathbb{R}^{d \times d} \), \( \tau : \sigma = \sum_{i,j=1}^d \tau^{i,j} \sigma^{i,j} \) is the doubly contracted product on \( \mathbb{R}^{d \times d} \) and \( b(u, v, w) = \sum_{i,j=1}^d \int_{\Omega} u_i (\partial_i v_j) w_j dx \).
Lemma 1.2 (Properties of $b$) Under Hypotheses (2), $b$ is a trilinear continuous form on $H^1_0(\Omega)^3$ and
\[ b(\pi, \nu, \nu) = 0, \forall \pi \in E(\Omega), \nu \in H^1_0(\Omega), \tag{4} \]
\[ b(\pi, \nu, \nu) = -b(\pi, \nu, \nu), \forall \pi \in E(\Omega), (\nu, \nu) \in H^1_0(\Omega). \tag{5} \]
as it is mentioned in [14, Ch.II, Lemma 1.2 and 1.3]

Remark 1.3 Under Hypothesis (2), the existence of a weak solution $(\pi, p)$ to Problem (1) in the sense of Definition 1.1 follows from [14, Ch.II, Theorem 1.2]. Moreover, [14, Ch.II, Theorem 1.2] gives us the uniqueness of the weak solution $(\pi, p)$ dealing with a condition on $\nu$, $f$ and $G$.

2 Gradient Discretisation for the incompressible steady Navier-Stokes problem

Definition 2.1 A gradient discretisation $D$ for the incompressible steady Navier-Stokes problem, with homogeneous Dirichlet’s boundary conditions, is defined by $D = (X_{D,0}, \Pi_D, \nabla_D, Y_D, \chi_D, \text{div}_D)$, where the discrete spaces and operators are assumed to verify the following properties.

1. $X_{D,0}$ is a finite-dimensional vector space on $\mathbb{R}$.
2. $Y_D$ is a finite-dimensional vector space on $\mathbb{R}$.
3. The linear mapping $\Pi_D : X_{D,0} \to L^2(\Omega)$ is the reconstruction of the approximate velocity field.
4. The linear mapping $\chi_D : Y_D \to L^2(\Omega)$ is the reconstruction of the approximate pressure, and must be chosen such that $\|\chi_D \cdot\|_{L^2(\Omega)}$ is a norm on $Y_D$. We then set $Y_{D,0} = \{q \in Y_D, \int_{\Omega} \chi_D q \, dx = 0\}$.
5. The linear mapping $\nabla_D : X_{D,0} \to L^2(\Omega)^d$ is the discrete gradient operator. It must be chosen such that $\|\cdot\|_D := \|\nabla_D \cdot\|_{L^2(\Omega)^d}$ is a norm on $X_{D,0}$.
6. The linear mapping $\text{div}_D : X_{D,0} \to L^2(\Omega)$ is the discrete divergence operator.

The coercivity of a sequence of gradient discretisations ensures that a discrete Sobolev inequality, a control of the discrete divergence and a discrete Ladyzenskaja-Babuka-Brezzi (LBB) condition can be established, all uniform
Definition 2.2 (Coercivity) Let $D$ be a discretisation in the sense of Definition 2.1. Let $q \in \mathbb{N}$ and let $C_D$ and $\beta_D$ be defined by

$$C_D = \max_{v \in X_{D,0}, \|v\|_D = 1} \|\Pi_D v\|_{L^q(\Omega)} + \max_{v \in X_{D,0}, \|v\|_D = 1} \|\operatorname{div}_D v\|_{L^2(\Omega)},$$

where $2 \leq q \leq \infty$ if $d = 2$ and $2 \leq q \leq 6$ if $d = 3$.

$$\beta_D = \min\left\{ \max_{v \in X_{D,0}, \|v\|_D = 1} \int_{\Omega} \chi_D q \operatorname{div}_D v \, dx : q \in Y_{D,0} \text{ such that } \|\chi_D q\|_{L^2(\Omega)} = 1 \right\}.$$  

A sequence $(D_m)_{m \in \mathbb{N}}$ of gradient discretisations is said to be coercive if there exist $C_S \geq 0$ and $\beta > 0$ such that $C_{D_m} \leq C_S$ and $\beta_{D_m} \geq \beta$, for all $m \in \mathbb{N}$.

The following definition is not needed in [3], since, thanks to the linearity of the Stokes problem, only weak convergence results are needed, and strong convergence is resulting from the problem (by convergence of norms).

Definition 2.3 (Compactness) Let $D$ be a gradient discretisation in the sense of Definition 2.1. A sequence $(D_m)_{m \in \mathbb{N}}$ of gradient discretisations is said to be compact if, for all sequence $(u_m)_{m \in \mathbb{N}} \in X_{D_m,0}$ such that $\|u_m\|_{D_m}$ is bounded, the sequence $(\Pi_{D_m} u_m)_{m \in \mathbb{N}}$ is relatively compact in $L^2(\Omega)$.

The consistency of a sequence of gradient discretisations states that the discrete space and operators “fill in” the continuous space as the discretisation is refined.

Definition 2.4 (Consistency) Let $D$ be a gradient discretisation in the sense of Definition 2.1 and let $S_D : H^1_0(\Omega) \to [0, +\infty)$, and $\tilde{S}_D : L^2_0(\Omega) \to [0, +\infty)$ be defined by

$$\forall \varphi \in H^1_0(\Omega), \quad S_D(\varphi) = \min_{v \in X_{D,0}} \left( \|\Pi_D v - \varphi\|_{L^2(\Omega)} + \|\nabla_D v - \nabla \varphi\|_{L^2(\Omega)} + \|\operatorname{div}_D v - \operatorname{div} \varphi\|_{L^2(\Omega)} \right)$$

and

$$\forall \psi \in L^2_0(\Omega), \quad \tilde{S}_D(\psi) = \min_{z \in Y_{D,0}} \|\chi_D z - \psi\|_{L^2(\Omega)}.$$
A sequence \((D_m)_{m \in \mathbb{N}}\) of gradient discretisation is said to be consistent if, for all \(\varphi \in H_0^1(\Omega)\), \(S_{D_m}(\varphi)\) tends to 0 as \(m \to \infty\) and, for all \(\psi \in L_0^2(\Omega)\), \(\tilde{S}_{D_m}(\psi)\) tends to 0 as \(m \to \infty\).

**Definition 2.5 (Limit-conformity)** Let \(D\) be a gradient discretisation in the sense of Definition 2.1 and let \(\overline{W}_D : Z(\Omega) \mapsto [0, +\infty)\), with

\[
Z(\Omega) = \{ (\varphi, \psi) \in L^2(\Omega)^d \times L^2(\Omega), \text{div}\varphi - \nabla\psi \in L^2(\Omega) \},
\]

be defined by

\[
\forall (\varphi, \psi) \in Z(\Omega), \quad \overline{W}_D(\varphi, \psi) = \max_{v \in X_{D,0}, \|v\| = 1} \left( \int_\Omega [\nabla_D v : \varphi + \Pi_D v \cdot (\text{div}\varphi - \nabla\psi) - \psi \text{div}_D v] \, dx \right).
\]

A sequence \((D_m)_{m \in \mathbb{N}}\) of gradient discretisations is said to be limit-conforming if, for all \((\varphi, \psi) \in Z(\Omega)\), \(\overline{W}_{D_m}(\varphi, \psi)\) tends to 0 as \(m \to \infty\).

### 3 Gradient Scheme

**Definition 3.1 (Discretisation of the trilinear form)** Let \(D\) be a gradient discretisation in the sense of Definition 2.1, we define \(B_D : X_{D,0}^d \mapsto L^2(\Omega)\) such that

\[
B_D(u, v, w) = \sum_{i,j=1}^{d} \int_\Omega \Pi_D^{(i)} u \nabla_D^{(i,j)} v \Pi_D^{(j)} w \, dx.
\]

We define our discrete bilinear form \(b_D\) following the same idea as the Finite Elements method:

\[
b_D(u, v) = \frac{1}{2} (B_D(u, u, v) - B_D(u, v, u)).
\]

**Remark 3.2 (Property of the discrete bilinear form)** With the previous definition of \(b_D\), we can remark that we get the same property as the continuous trilinear form which is that for all \(u \in X_{D,0}\), we get that \(b_D(u, u) = 0\).

The gradient scheme for the incompressible steady Navier-Stokes problem is based on a discretisation of the weak formulation \(3\), in which the continuous spaces and operators are replaced with discrete ones (in \(3\), we wrote the property "\(\text{div}\, \mathbf{u} = 0\)" using test functions to make clearer this parallel between
the weak formulation and the gradient scheme). If $D$ is a gradient discretisation in the sense of Definition 2.1 and $b_D$ is defined by Definition 3.1, the scheme is given by:

$$
\begin{cases}
u \int_{\Omega} \nabla D u \cdot \nabla D v\, dx + b_D(u,v) \\
- \int_{\Omega} \chi_D p \text{div}_D D v \, dx = \int_{\Omega} (f \cdot \Pi_D v + G : \nabla D v) \, dx, \forall v \in X_D,0,
\end{cases}
$$

Our main result for the incompressible steady Navier-Stokes problem is the following theorem.

**Theorem 3.3 (Convergence of the scheme)** Under Hypotheses (2), let $(D_m)_{m \in \mathbb{N}}$ be a sequence of gradient discretisations in the sense of Definition 2.1 which is consistent, limit-conforming, coercive and compact in the sense of Definition 2.4, 2.5, 2.2 and 2.3. Then for any $m$ there exists at least a solution $(u_{D_m}, p_{D_m})$ to (8) with $D = D_m$ and $b_D$ defined by Definition 3.1. Moreover, as $m \to \infty$, there exists a subsequence of $(D_m)_{m \in \mathbb{N}}$ again denoted $(D_m)_{m \in \mathbb{N}}$ and there exists $(\Pi, \nabla, \nabla \Pi, \nabla D, \nabla D, \text{div} D)$, weak solution of the incompressible steady Navier-Stokes problem (1) in the sense of Definition 1.1, such that

- $\Pi_D u_{D_m}$ converges to $\Pi$ in $L^2(\Omega)$,
- $\nabla D u_{D_m}$ converges to $\nabla \Pi$ in $L^2(\Omega)^d$,
- $\chi_D p_{D_m}$ converges to $p$ in $L^2(\Omega)$.

4 Examples of gradient discretisations

In this section, we assume that the boundary of $\Omega \subset \mathbb{R}^d$ is polygonal.

4.1 The MAC scheme on rectangular parallelepipedic meshes

The Marker-And-Cell (MAC) scheme [11, 12, 15] can be easily defined on domains whose boundary is the union of subparts parallel to the axes. We assume that it is possible to grid $\Omega$ using a finite number of rectangular parallelepipedic gridblocks. We then define the gradient discretization $D = (X_D, Y_D, \Pi_D, \chi_D, \nabla D, \text{div} D)$ (the detailed notations are given in [3] in a 2D case) by:
1. $X_D^{0,0}$ is the set of families of real values at the center of all internal faces of the mesh, discretizing the velocity in the normal direction to the face,

2. $Y_D$ is the set of all families of real values at the center of the gridblocks, discretizing the pressure,

3. $\Pi_D$ is the piecewise constant reconstruction of the velocity in the $d$ staggered rectangular parallelepipedic grids, whose centers of the gridblocks are the centers of the faces normal to each of the $d$ basis vectors of $\mathbb{R}^d$,

4. $\chi_D$ is the reconstruction of the pressure, piecewise constant in all the gridblocks,

5. $\nabla_D u = (\nabla_D^{(i,j)} u_{i,j=1,...,d})$ is a piecewise constant approximation of the $j$-th derivative of the $i$-th component of the velocity, defined by a standard finite difference formula,

6. $\text{div}_D u = \text{Tr}(\nabla_D u) = \sum_{i=1}^{d} \nabla_D^{(i,i)} u$.

We then have the following result.

**Proposition 4.1 (Gradient Scheme properties of the MAC scheme)**

Let $D_m = (X_D^{m,0}, Y_D^{m}, \Pi_D^{m}, \chi_D^{m}, \nabla_D^{m}, \text{div}_D^{m})$ be defined as in the beginning of this section, with $h_D^m$ tending to 0 as $m \to \infty$. Then $D_m$ is a gradient discretisation in the sense of Definition 2.1 and the family $(D_m)_{m \in \mathbb{N}}$ is consistent, limit-conforming, coercive and compact in the sense of Definitions 2.4, 2.5, 2.2 and 2.3.

**Proof**

The proof of the consistency and limit-conformity as well as the proof of the lower bound on $\beta_D$ can be found in [3].

Since the definition of $\nabla_D$ is corresponding to the discrete gradient of a finite volume scheme on a mesh satisfying the usual orthogonality property, the bound on $C_D$ is a consequence of the discrete Sobolev inequality obtained in [1] or [6, Lemma 9.5 p. 790] (the control of $\text{div}_D$ by $\nabla_D$ is then trivial from its definition).

The compactness property is resulting from [6, Lemma 9.3 p. 770]. □

### 4.2 The Crouzeix-Raviart scheme

We consider a simplicial mesh $\mathcal{T}$. The Crouzeix-Raviart scheme [2] can be seen as a gradient scheme with the gradient discretisation defined by:
1. $X_D,0$ is the vector space containing the families of elements of $\mathbb{R}^d$ defined at the center of all internal faces of the mesh,

2. $Y_D$ is the vector space containing the families of real values defined at the center of all simplices,

3. The linear mapping $\Pi_D$ is the nonconforming piecewise affine reconstruction of each component of the velocity,

4. The linear mapping $\chi_D$ is the piecewise constant reconstruction in the simplices,

5. The linear mapping $\nabla_D$ is the so-called “broken gradient” of the velocity, defined as the piecewise constant field of the velocity’s gradients in each simplex,

6. The linear mapping $\text{div}_D$ is the discrete divergence operator, with piecewise constant values in the cells equal to the balance of the normal velocities over the cell’s faces.

**Proposition 4.2 (Gradient Scheme properties of the Crouzeix-Raviart scheme)**

Let $(\mathcal{T}_m)_{m \in \mathbb{N}}$ be a sequence of triangulations of $\Omega$ satisfying a regularity condition. We define $D_m = (X_{D,m}, 0, Y_{D,m}, \Pi_{D,m}, \chi_{D,m}, \nabla_{D,m}, \text{div}_{D,m})$ as above for $\mathcal{T} = \mathcal{T}_m$, and we assume that $h_{\mathcal{T}_m} \to 0$ as $m \to \infty$. Then $D_m$ is a gradient discretisation in the sense of Definition 2.1 and the family $(D_m)_{m \in \mathbb{N}}$ is consistent, limit-conforming, coercive and compact in the sense of Definitions 2.4, 2.5, 2.2 and 2.3.

**Proof** The coercivity is a consequence of the results given in [10]. The consistency and limit-conformity are proved in [3]. The compactness property is proved in [9, Theorem 3.3]. □

**4.3 Conforming Taylor–Hood scheme**

The Taylor–Hood scheme [13] on a simplicial mesh $\mathcal{T}$ (triangles in 2D or tetrahedra in 3D) can be seen as the gradient scheme corresponding to the gradient discretisation $D = (X_D, 0, Y_D, \Pi_D, \chi_D, \nabla_D, \text{div}_D)$ defined by:

1. $X_D,0$ is the vector space of the degrees of freedom of the $\mathbb{P}^2$ finite element for the $d$ components of the velocity vanishing at the boundary, and $Y_D$ is the vector space of the degrees of freedom of the $\mathbb{P}^1$ finite element for the pressure,
2. $\Pi_D$ and $\chi_D$ are respectively the conforming reconstructions of the velocity and the pressure obtained through the $\mathbb{P}^2$ and $\mathbb{P}^1$ finite element basis functions,

3. $\nabla_D$ and $\text{div}_D$ are the conforming operators $\nabla_D = \nabla \circ \Pi_D$ and $\text{div}_D = \text{div} \circ \Pi_D$.

**Proposition 4.3 (Gradient Scheme properties of the Taylor-Hood scheme)**

Let $(T_m)_{m \in \mathbb{N}}$ be a sequence of triangulations of $\Omega$ satisfying a regularity condition. We assume that every mesh element has at least $d$ edges in $\Omega$ and that $h_{T_m} \to 0$ as $m \to \infty$. Let $D_m = (X_{D_m}, 0, Y_{D_m}, \Pi_{D_m}, \chi_{D_m}, \nabla_{D_m}, \text{div}_{D_m})$ corresponding to the conforming Taylor–Hood scheme for $T_m$. Then $D_m$ is a gradient discretisation in the sense of Definition 2.1 and the family $(D_m)_{m \in \mathbb{N}}$ is consistent, limit-conforming, coercive and compact in the sense of Definitions 2.4, 2.5, 2.2 and 2.3.

**Proof** Since the scheme is conforming, the coercivity and the compactness properties are a consequence of the continuous Sobolev inequalities and Rellich theorem. The consistency and limit-conformity are proved in [3]. □
