Abstract

A new species of bladed Bangiales, *Pyropia orbicularis* sp. nov. M.E. Ramírez, L. Contreras-Porcia & M.L. Guillemin, has been described for the first time from the central coast of Chile based on morphology and molecular analyses. The new species was incorrectly known as *Porphyra columbina* (now *Pyropia columbina* (Montagne) W.A. Nelson), and it can be distinguished from other species of *Pyropia* through a range of morphological characteristics, including the shape, texture and colour of the thallus, and the arrangement of the reproductive structures on the foliose thalli. Molecular phylogenies based on both the mitochondrial COI and plastid *rbcL* gene regions enable this species to be distinguished from other species within *Pyropia*. *Pyropia orbicularis* sp. nov. belongs to a well supported clade of *Pyropia* from the southern oceans that include specimens from the South Pacific (North, South, Chatham, Stewart, Auckland, and Campbell Island, New Zealand; New South Wales, and Macquarie Island, Australia) including *P. columbina* and *P. plicata*. Within this clade, the highest sequence identity was observed between *Pyropia orbicularis* sp. nov. and *Pyropia* sp. FIC from the Falkland Islands.

Key words: Bangiales, COI, Morphology, *Porphyra*, *Pyropia*, *rbcL*, South Pacific

Introduction

In a recent worldwide study of Bangiales (Rhodophyta) based on molecular analysis using nuclear (SSU rRNA) and chloroplast *rbcL* regions, Sutherland *et al.* (2011) recognized the existence of fifteen genera of which seven are filamentous and eight foliose. Of the foliose genera, *Porphyra* sensu lato, which has representatives in all seas, has undergone many changes in its classification in the last decade (e.g. Anilkumar & Rao 2005, Yoshida *et al.* 2005, Kikuchi *et al.* 2010, Nelson & Broom 2010, Kucera & Saunders 2012, Mateo-Cid *et al.* 2012, Nelson 2013).

The economic and cultural importance of *Porphyra* sensu lato is widely known and appreciated in Asian countries, notably Japan and China, North and South America, Australia and New Zealand (Aguilar-Rosas *et al.* 1998, Jian & Chen 2001, He & Yarish 2006, Blouin *et al.* 2011) and has been one of the red algal genera with the largest production and marketing worldwide. In Chile, species of the genus *Pyropia* and *Porphyra*, specifically the taxon known as *Porphyra columbina* Montagne (now *Pyropia columbina* (Montagne) W.A Nelson), are commonly called "luche or lucht" and have been harvested and consumed since the late Pleistocene by coastal populations in the country (Seguel & Santelices 1988, Buschmann *et al.* 2001, González & Santelices 2003, Dillehay *et al.* 2008). It is reported that the species, under the name *P. columbina*, is highly seasonal and grows abundantly between September-March along the upper intertidal zone of the Chilean coast from Arica (18°S) to Tierra del Fuego (55°S) (Ramírez & Santelices 1991, Hoffman & Santelices 1997). It is also known that this species may lose up to 90% of fresh weight during low tide (Contreras-Porcia *et al.* 2011) and several mechanisms of tolerance are activated during this adverse cellular condition in comparison with many other species

(Contreras-Porcia *et al.* 2011, 2012, 2013; Flores-Molina *et al.* 2013). Nevertheless, the identity of the taxon “*Porphyra columbina*” in Chile has been questioned principally because (1) the majority of Chilean specimens to which this name has been applied belong to warm temperate localities (see discussion in Nelson & Broom 2010) and (2) because the external morphology of specimens assigned to *P. columbina* in the Chilean coast is not consistent with the original description by Montagne (1842) or specimens recently re-evaluated by Nelson & Broom (2010). Thus, given their importance in ecophysiological studies, aquaculture management plans and biotechnological applications, it is crucial to classify this species and to be able to distinguish it from the many other foliose Bangiales, the majority of which are undescribed (J. Brodrie, L. Contreras, E. Macaya and M-L. Guillemin unpublished data) along the Chilean coast.

Molecular studies have revealed cryptic speciation within the genus *Porphyra* sensu lato (e.g. Broom *et al.* 1999, 2004, 2010, Brodrie *et al.* 2007, Lindstrom 2008). Brodrie *et al.* (in preparation), who sequenced samples of a foliose species assigned to “*Porphyra columbina*” collected from the length of the Chile coast, concluded, as had Sutherland *et al.* (2011), that there was no evidence of this species in the Chilean flora. They also concluded that of the foliose genera documented by Sutherland *et al.* (2011), three are present in Chile: *Porphyra*, *Pyropia* and *Wildemania*. Gross morphology within and between species is extremely diverse, varying from linear through ovate, to orbicular or funnel shaped, with entire or dentate, planar, undulate margins, and variable colour (yellow, olive green, brown and red-brown). In this context, and taking into account new molecular data gathered from 197 samples distributed from Arica (18°S) to Tierra del Fuego (55°S) (J. Brodrie, L. Contreras, E. Macaya and M-L. Guillemin unpublished data), the morphological and

molecular data suggest the absence of *P. columbina* along the Chilean coast. The aim of the present study was to documents and clarifies the taxonomic status of one of these populations present on the Central coast of Chile (Maitencillo beach, Valparaíso) based on morphological and molecular analysis of COI and *rbcL* genes.

Materials and methods

Collection of samples. A total of one hundred of *Porphyra* specimens previously identified as “*Porphyra columbina*” were collected from the upper and mid intertidal zone with low wave exposure along 300–500 m of coastline from Maitencillo beach, Valparaíso, Chile (32°39’S 71°26’W) from March 2012 to January 2013. Samples were stored immediately in plastic bags containing seawater and transported to the laboratory in a cooler at 5–7 °C. In the laboratory, algae were rinsed with 0.22 µm-filtered seawater and immediately pressed as herbarium vouchers. Subsamples were dried in desiccant silica gel (Vetec Analytical Reagents, Brazil) for subsequent DNA analysis, and other subsamples kept in filtered fresh seawater at 14 ± 2 °C, under a $30\text{--}50 \mu\text{mol m}^{-1} \text{s}^{-1}$ of photon flux density (Growth Chamber W-19, Amilab, Chile) prior to morphological analysis. The holotype specimen (MAI0007) was housed in the herbarium of the National Museum of Natural History, Chile under the number SGO162483. One isotype (MAI0006) was housed in the Colección de Flora y Fauna Prof. Patricio Sánchez Reyes (SSUC), Departamento de Ecología, Pontificia Universidad Católica de Chile (SSUC-7758).

Morphological observations. Thallus shape, colour, texture and rhizoid disposition was described from fifty plants. Also, microscopic observations of hand-cut transverse sections were used to determine the tissue thickness, number of cell layers and

identification of reproductive structures. Dimensions of vegetative, rhizoidal cells and reproductive tissue (i.e. zygotosporangium and spermatangium) were measured and the number and size of zygospores per zygotosporangium, and spermatia per spermatangium were recorded. Images were made using a Nikon Microscopy Unit (Nikon Corp. Tokyo, Japan) coupled to a digital recording system (CoolSNAP-Procf, Media Cybernetics, Silver Spring, MD, USA) and analyzed using the Image Pro Plus Version 4.5 software (Media Cybernetics, Silver Spring, MD, USA).

DNA extraction and amplification. Dried algal tissue was finely grounded in liquid nitrogen. DNA was extracted following the protocol described by Saunders (1993), slightly modified by Faugeron et al. (2001). COI-5P was amplified using the primer pair GazF1 (5'-TCA ACA AAT CAT AAA GAT ATT GG -3') and GazR1 (5'-ACT TCT GGA TGT CCA AAA AAY CA -3'), following the amplification protocols of Saunders (2005). The chloroplastic gene *rbcL*, encoding the large subunit of the ribulose-1,5-bisphosphate carboxylase/oxygenase enzyme, was amplified using the primers F-*rbcL* (5'-TTG CAT AYG ATA TTG ATY TAT TTG AA-3') and R-*rbcS* (5'-RAG CTG TTT KTA AAG GWC CAC AA-3') and protocols published previously (Hommersand *et al.* 1994, Fredericq & López-Bautista 2002). For both markers, PCR amplifications were performed in a Perkin Elmer Gene Amp PCR System 9700 (Applied Biosystems, Foster City, USA). All PCR products were purified using UltraClean™ DNA Purification kits (MO BIO Laboratories, Carlsbad, USA) and sequenced using the forward and the reverse amplification primers by Macrogen Inc. (Seoul, South Korea). Sequences were edited using Chromas v. 2.33 (McCarthy 1997) and alignments were obtained using the CLUSTAL function of Mega v 5 (Tamura *et al.* 2011).

Sequences were obtained from 14 specimens (604 bp for the COI and 876 bp for the *rbcL*) and deposited in GENBANK. Specimen collection information and GENBANK accession numbers are detailed in Table 1. In addition to the new sequences of *Pyropia orbicularis* sp. nov. obtained in this study, 57 COI and 317 *rbcL* sequences were retrieved from GENBANK for further analyses. A complete list of specimens used in the molecular analyses is detailed in Table S1.

Molecular analysis. Two data sets were created for the COI and the *rbcL*, respectively. Three species belonging to the genus *Porphyra* were used as outgroups (i.e. *P. mumfordii*, *P. purpurea* and *P. umbilicalis*, Table S1). Each sequence data set was partitioned according to codon position. The best-fit models were estimated independently for each partition by the Akaike Information Criteria (AIC) implemented in TREEFINDER (Jobb *et al.* 2004) and the parameters of the different substitution models were estimated independently for each partition. AIC identified J2 + G model for the first codon position of the *rbcL*, J3 + G for the second codon position of the *rbcL*, J1 + G for the first codon position of the COI, GTR +G for the second codon position of the COI, and HKY for the third codon position of both genes. Phylogenetic relationships were inferred with a mixed model in a maximum likelihood framework by using TREEFINDER, version January 2008 (Jobb *et al.* 2004) and support for the nodes was assessed with 1,000 bootstrap pseudoreplicates.

Bayesian inference was performed using the general type of the best fit model parameters defined for each dataset using MrBayes v 3.1.2 (Huelsenbeck & Ronquist 2001). Four independent analyses were run with four chains each, for five million generations. Trees and parameters were sampled every 1,000 generations and the default parameters were used to fit temperature and swapping. The first 25% of sampled trees were

discarded as “burn-in” to ensure stabilization. The remaining trees were used to compute a consensus topology and posterior probability values.

Inter- and intraspecific uncorrected p-distances, were calculated in Mega v 5 (Tamura *et al.* 2011). Interspecific measures correspond to the pairwise distances between the *Pyropia* specimens used in the tree reconstruction; here the sequence of MAI0007 (i.e. holotype specimen, SGO162483) was used for *Pyropia orbicularis* *sp. nov.* Intraspecific sequence divergence was estimated in 12 species of *Porphyra* (2 for the COI and 12 for the *rbcL*, respectively) and 29 species of *Pyropia* (4 for the COI and 26 for the *rbcL*, respectively) for which multiple sequences were available in GENBANK (Table S1).

Results

Pyropia orbicularis* [M.E. Ramírez, L. Contreras-Porcia & M.L. Guillemin], *sp. nov.
(Figs 1–10, Fig. S1, Table 1-3)

Type: —CHILE. Maitencillo beach, Valparaíso, 32°39'S 71°26'W, coll. Contreras-Porcia, Núñez, Guajardo and Fierro, 12-10-2012, holotype: SGO162483 (Fig. 2), isotype: SSUC-7758

Gametophyte blades orbicular, 2.8–14 cm high and 4–16 cm wide, with an irregular undulate margin; monostromatic, 36–139 µm thick in transverse section, attached to rocky substratum by abundant rhizoidal cells at the base of the thallus. Colour green-grey to brown on outer edges. Vegetative cells with a single stellate chloroplast. Monoecious; reproductive structures marginal; spermatangial sori pale golden patches interspersed with

184 deep red zygotosporangia and sterile cells; zygotosporangia in packets of a2/b2/c2 and
 185 spermatangia in packets of a4/b4/c4.
 186

187 **Habitat:** —Upper and mid intertidal rock.

188 **Etymology:** —orbicularis for the typical shape of the blades, rounded or orbicular outline
 189

190 **Molecular analysis:** — For the chloroplast marker *rbcL* (876 bp), only one haplotype was
 191 observed for the 13 sequenced individuals of *Pyropia orbicularis* *sp. nov.* Three haplotypes
 192 were detected for the mitochondrial marker COI, with 3 polymorphic sites along the 604
 193 base pairs fragment sequenced (13 sequenced individuals, Table 1). Figures 9 and 10 show
 194 the maximum likelihood phylograms constructed with the *rbcL* sequences of 89 *Pyropia*
 195 specimens, and the COI sequences of 34 *Pyropia* specimens, respectively. For both genes,
 196 tree topologies based on Bayesian and maximum likelihood analyses were largely
 197 congruent and shared comparable support values for major nodes (Figs 9 and 10).

198 For the COI, all specimens from Maitencillo beach form a strongly supported monophyletic
 199 lineage (support values >99%, Fig. 10). For the *rbcL*, the gene where the more complete
 200 data set is available, *Pyropia orbicularis* *sp. nov.* form a strongly supported monophyletic
 201 clade with *Pyropia* sp. FIC collected in Port Stanley in the East Falkland Island (Broom *et*
 202 *al.* 2010) (support values >99%, Fig. 9). The uncorrected p-distance between *P. orbicularis*
 203 *sp. nov.* and *P. sp.* FIC is of 0.57 % for the *rbcL* (i.e. 5 substitutions). *Pyropia orbicularis*
 204 *sp. nov.* is part of a well-supported clade encompassing 16 *Pyropia* species from the
 205 southern hemisphere that includes specimens from the Southern Ocean (King George
 206 Island), the South Atlantic (South Africa and Falkland Islands) and the South Pacific
 207 (North, South, Chatham, Stewart, Auckland, and Campbell Islands, New Zealand, New

South Wales, and Macquarie Island, Australia) (Fig. 9). This southern hemisphere clade includes *P. columbina* (Nelson & Broom 2010, Broom *et al.* 2010), where the uncorrected p-distance between *P. orbicularis sp. nov.* and *P. columbina* is of $3.11 \pm 0.54\%$ for the *rbcL* (i.e. 27.28 ± 5.00 substitutions). The COI data set did not allow to confirm the position of *P. sp. FIC* as the sister species of *P. orbicularis sp. nov.* within a southern hemisphere *Pyropia* clade owing to the low number of *Pyropia* COI sequences available in GENBANK (three times fewer than for the *rbcL*). Indeed, no COI sequences are available for the 15 other southern hemisphere species.

Interspecific divergences in the genus *Pyropia* (mean 12.81% for COI and 5.64% for the *rbcL*) are much deeper than the intraspecific divergences in both the genus *Pyropia* and *Porphyra* (mean 0.05% and 0.41% for COI and 0.09% and 0.17% for *rbcL*, for *Pyropia* and *Porphyra*, respectively) (Table 3). Between specimens of *P. orbicularis sp. nov.*, intraspecific divergences for the COI range from 0.00% up to 0.66% while for the *rbcL*, where only one haplotype was detected, intraspecific divergences were of 0.00% (Table 3).

Discussion

The description of a new species of *Pyropia*, *P. orbicularis sp. nov.*, resolves the identity of the species misidentified as *Porphyra columbina*, now *Pyropia columbina* (Montagne) W.A. Nelson, from the population Maitencillo beach; central coast of Chile. *Pyropia orbicularis sp. nov.* and *P. columbina* exhibit morphological differences in both the shape and length of the thallus. The gametophyte thallus of *P. orbicularis* reaches a size of 14 cm, while that of *P. columbina* reaches up to 5 cm (Montagne 1842, Nelson & Broom 2010). Both species are distinguishable by the colour and thickness of the blade. *P. columbina* has

231 a pink-gray colour (Nelson & Broom 2010), and a thin thallus (75-90 μm), whereas *P.*
232 *orbicularis* is green-grey to brown in colour and has a thick thallus (36-139 μm).

233 These morphological differences are congruent with the molecular data, as measured using
234 the COI and *rbcL* markers. Despite both species being positioned within a clade conformed
235 of several *Pyropia* species from the Southern Pacific, the divergence between *P. orbicularis*
236 and *P. columbina* is up to 3%. Geographically, *P. columbina* has, until now, been confined
237 to the temperate, cold waters of New Zealand's sub-Antarctic Auckland and Campbell
238 Islands, the Antipodes Islands, and the Falkland Islands. The apparent limitation of the
239 distribution of *P. columbina* up to 51°S raises questions about the reports of this species on
240 the central coast of Chile. Another species which is close to *P. orbicularis* in our
241 phylogenetic analysis is the recently described *Pyropia plicata* W.A. Nelson from the New
242 Zealand region, distributed in the North, South and Chatham Islands (Nelson 2013).
243 However, this species is different from *P. orbicularis* primarily in the configuration of the
244 reproductive regions (Table 2).

245 With molecular phylogenetic analysis, sequences of *P. orbicularis* from Chile were
246 shown to be similar to the species coded as *Pyropia* sp. FIC from the Falkland Islands
247 (Broom *et al.* 2010). The values of uncorrected p-distance for the *rbcL* between *P.*
248 *orbicularis* and *Py. FIC* (0.57%) are low and fall within the limit of the *Pyropia*
249 intraspecific genetic distance for this gene (0.00%-0.82%, Table 3). Broom *et al.* (2010)
250 described some morphological characteristics of the thallus from *Pyropia sp FIC* that
251 coincide with the descriptions of *P. orbicularis* from Maintencillo beach (e.g. male and
252 female regions of the blade intermixed; had a brownish-red thallus), which could validate
253 the inclusion of *Py. FIC* within *P. orbicularis*. However, as only one locality has been

sampled and only one *rbcL* haplotype is available for both species it is premature to consider that *Pyropia* sp. FIC of the Falkland Islands is conspecific with *Pyropia orbicularis* sp. nov. Considering the large latitudinal gradient along the Pacific coast of Chile, where *P. columbina* was previously reported, a more detailed study of *P. orbicularis* sp. nov. is needed in order to better determine the amount of genetic diversity present within this species and to delimit its latitudinal range. In addition, a more detailed molecular and morphological analysis of the Bangiales flora from Chile will be necessary to unravel the possible presence of cryptic diversity along the South Eastern, Pacific coast.

Acknowledgments

This work was supported by DI-59-12/R and FONDECYT 1120117 to L.C-P., and INACH T_16-11 to M.L.G. We are especially grateful to E. Guajardo, C. Fierro, J. Zapata and A. Contreras for their fieldwork assistance and to V. Flores, J. Reyes, G. Peralta and D. Pérez for technical support. Also, we appreciate the constructive comments from the Editor and from anonymous reviewers that helped improved the manuscript.

397 **Fig. 3.** Surface view of vegetative region of the thallus. **Fig. 4.** Surface view of basal,
 398 rhizoidal cells. **Fig. 5.** Cross-section of vegetative region of thallus. **Fig. 6.** Trichogyne
 399 (arrow). **Fig. 7.** Surface view of zygotosporangia. **Fig. 8.** Fertile region of the blade with
 400 packets of developing zygotosporangia (larger) and packets of spermatangia (smaller).

402 **FIGURE 9.** Maximum likelihood rooted tree for *rbcL* sequences (876 bp) of *Pyropia*.
403 *Porphyra mumfordii*, *P. purpurea* and *P. umbilicalis*, were used as outgroups. For each
404 node, Maximum Likelihood bootstrap values and Bayesian Posterior Probabilities are
405 indicated (ML/BPP). Only high support values (>60) are shown; - = clade not observed in
406 the Bayesian Inference. Next to collapsed branches are abbreviated species or sequences
407 names, GENBANK accession numbers have been omitted for brevity but are listed in Table
408 S1 (Supporting Information, sequences highlighted in grey). Region where specimens were
409 collected are indicated within parenthesis: SA = South Atlantic, SP = South Pacific, SO =
410 Southern Ocean. Thick lines highlight the southern hemisphere clade that include *Pyropia*
411 *orbicularis* *sp. nov.*

412

413 **FIGURE 10.** Maximum likelihood rooted tree for COI sequences (604 bp) of *Pyropia*. *Porphyra mumfordii*, *P. purpurea* and *P.*
 414 *umbilicalis*, were used as outgroups. For each node, Maximum Likelihood bootstrap values and Bayesian Posterior Probabilities are
 415 indicated (ML/BPP). Only high support values (>60) are shown; - = clade not observed in the Bayesian Inference. Next to collapsed
 416 branches are abbreviated species or sequences names, GENBANK accession numbers have been omitted for brevity but are listed in
 417 Table S1 (Supporting Information, sequences highlighted in grey).

418 **TABLE 1:** Specimen collection information, voucher number and GenBank accession numbers of individuals from Maitencillo beach,
419 Valparaíso, Chile, sequenced during this work. See morphological features in Supporting Information (Fig. S1).
