Simultaneous Empirical Interpolation and Reduced Basis method for non-linear problems

IRMA (UMR 7501) 7 rue René-Descartes 67084 Strasbourg Cedex

Abstract

In this paper, we focus on the reduced basis methodology in the context of non-linear non-affinely parametrized partial differential equations in which affine decomposition necessary for the reduced basis methodology are not obtained [4, 3]. To deal with this issue, it is now standard to apply the EIM methodology [8, 9] before deploying the Reduced Basis (RB) methodology. However the computational cost is generally huge as it requires many finite element solves, hence making it inefficient, to build the EIM approximation of the non-linear terms [9, 1]. We propose a simultaneous EIM Reduced basis algorithm, named SER, that provides a huge computational gain and requires as little as \( N + 1 \) finite element solves where \( N \) is the dimension of the RB approximation. The paper is organized as follows: we first review the EIM and RB methodologies applied to non-linear problems and identify the main issue, then we present SER and some variants and finally illustrates its performances in a benchmark proposed in [9]. To cite this article: C. Daversin, C. Prud’homme, C. R. Acad. Sci. Paris, Ser. I 340 (2015).

1. Introduction

Reduced order modeling is more and more used in engineering problems due to efficient evaluation of quantities of interest. The Reduced Basis Method (see [2, 3, 4, 5, 6, 7]) has been especially designed for real-time and many-query contexts, and cover a large range of problems among which non-affinely parametrized Partial Differential Equations (PDE). A core enabler of this method is the so-called offline/online decomposition of the problem. This allows for computing costly parameter independent terms that depend solely on the finite element dimension. However such decomposition is not necessarily or readily available in particular for non-affine/non-linear problems. The Empirical Interpolation Method (EIM, see [8, 9]) has been developed to recover this core ingredient and is used prior to the reduced basis methodology on industrial based applications, see e.g. [1]. However the EIM building step can be costly when the terms are non-linear and requires many non-linear finite element solves. It is a deterring trait for this methodology which forbids its application to non-linear applications.

In this paper, we propose a Simultaneous EIM-RB (named SER) construction that requires only but a few finite element solves and which builds together the affine decomposition as well as the RB ingredient. To start we

Email addresses: daversin@math.unistra.fr (Cécile Daversin), prudhomme@unistra.fr (Christophe Prud’homme)
first give an overview of both Reduced Basis and Empirical Interpolation methods in non-affinely parametrized PDE context to recall the necessary notions. Based on these considerations, a second part makes an assessment of the proposed simultaneous approach discussing the changes to be made in the EIM offline step. The last part illustrates our method with preliminary results obtained on a benchmark introduced in [9].

2. Preliminaries

Let \( u(\mu) \) be a solution of a non-linear parametrized PDE, where \( \mu \) is the \( p \)-vector of inputs (\( \mu \in \mathcal{D} \subset \mathbb{R}^p \) the parameter space). Considering the Hilbert space \( X \equiv H^1_0(\Omega) \), the variational formulation of the PDE consists in finding \( u(\mu) \in X \) as a root of a functional \( r \) such that

\[
  r(u(\mu), v; \mu) = 0 \quad \forall v \in X.
\]

We denote \( \mathcal{N} \) the dimension of the finite element approximation space \( X^\mathcal{N} \subset X \), and \( u_\mathcal{N}(\mu) \) the associated finite element approximation of \( u(\mu) \) solution of (1).

In the following, we use a Newton algorithm to deal with the non-linearity. Denoting \( k^th \) Newton’s iteration, and \( j \) the Jacobian associated with the functional \( r \), the problem consists in finding \( \hat{\delta}^{k+1} u(\mu) \equiv k+1 u(\mu) - k u(\mu) \in X^\mathcal{N} \) and thus \( k+1 u(\mu) \in X^\mathcal{N} \) such that

\[
  j(\delta^{k+1} u(\mu), v; k u(\mu)) = -r(k u(\mu), v; \mu) \quad \forall v \in X^\mathcal{N}
\]

at each iteration \( k \).

If \( j \) and \( r \) depend affinely in \( \mu \), there exist positive integers \( Q_j \) and \( Q_r \), \( \mu \)-dependent functions \( \theta_j^\mu \), \( \theta_r^\mu \) and functions \( j^\mu \), \( r^\mu \) \((1 \leq q_j \leq Q_j, 1 \leq q_r \leq Q_r) \) allowing to write such affine decompositions

\[
  j(u, v; \mu; k u) = \sum_{q_r=1}^{Q_r} \theta^\mu_r(k u; \mu) r^\mu(u, v) \quad r^\mu(u, v; \mu) = \sum_{q_j=1}^{Q_j} \theta^\mu_j(k u; \mu) j^\mu(u, v) \quad \forall u, v \in X^\mathcal{N}, \quad \forall \mu \in \mathcal{D}
\]

For non-affinely parametrized problems, \( j \) and \( r \) depend on a set \( \{w_i(u(\mu), x; \mu)\}_i \) of non-affine functions

\[
  j(u, v; \mu; k u; \{w_i(u(\mu), x; \mu)\}_i) \hat{\delta}^{k+1} u(\mu) = -r(k u(\mu), v; \mu; \{w_i(u(\mu), x; \mu)\}_i)
\]

and the affine decomposition (3) doesn’t exist owing to \( w_i(u(\mu), x; \mu) \) definition. In order to recover an affine decomposition for (4), we build an affine approximation \( w_{\mathcal{M}}(u(\mu), x; \mu) \) of \( w_i(u(\mu), x; \mu) \)

\[
  w_{\mathcal{M}}(u(\mu), x; \mu) = \sum_{m=1}^{M} \beta_{i,m}(u(\mu); \mu) q_{i,m}(x) \quad \forall i
\]

2.1. Empirical Interpolation Method

In order to build an affine approximation \( w_M(u(\mu), x; \mu) = \sum_{m=1}^{M} \beta^M_{m}(u(\mu); \mu) q_M(x) \) of a non-affine parameter dependent function \( w \), we first introduce a sample \( \bar{S}_M = \{\mu_1, \ldots, \mu_M\} \subset \mathcal{D}_M \), and the associated function space \( \bar{W}_M = \text{span}\{\bar{\xi}_m \equiv w(u(\mu_m), x; \mu_m), 1 \leq m \leq M\} \). These sets are built from a subset \( \Xi \subset \mathcal{D} \), in which the first sample point \( \mu_1 \) is picked (assuming that \( \bar{\xi}_1 \neq 0 \)). The basis functions \( q_m \) are based on \( \bar{\xi}_m \), and establishing of \( \beta^M_m \) coefficients requires, online, the solution of a \( M \times M \) system, ensuring that the EIM approximation \( w_M(u, x; \mu) \) is exact on a set of interpolation points \( \{t_i\}_i \).

\[
  \bar{S}_1 = \{\mu_1\}, \quad \bar{\xi}_1 = w(u(\mu_1), x; \mu_1), \quad \bar{W}_1 = \text{span}\{\bar{\xi}_1\} \quad t_1 = \operatorname{arg sup}_{x \in \Omega} |\bar{\xi}_1(x)|, \quad q_1 = \frac{\bar{\xi}_1(x)}{\bar{\xi}_1(t_1)}
\]

For \( M \geq 2 \), the sample points \( \mu_M \) are determined from a Greedy algorithm:

\[
  \bar{\mu}_M = \operatorname{arg max}_{\mu \in \Xi} \inf_{z \in \bar{W}_{M-1}} ||w(\mu; \cdot; \mu) - z||_{L^\infty(\Omega)}, \quad \bar{\xi}_M = w(u(\bar{\mu}_M), x; \bar{\mu}_M), \quad \bar{S}_M = \bar{S}_{M-1} \cup \{\bar{\mu}_M\}, \quad \bar{W}_M = \bar{W}_{M-1} \oplus \text{span}\{\bar{\xi}_M\}
\]

The system ensuring the exactness of \( w_{M-1} \) at \( \{t_i\}_{i=1}^{M-1} \), gives \( w_{M-1}(u(\bar{\mu}_M), x; \bar{\mu}_M) \), leading to the residual \( r_M \) defined as \( r_M(x) = w(u(\bar{\mu}_M), x; \bar{\mu}_M) - w_{M-1}(u(\bar{\mu}_M), x; \bar{\mu}_M) \) on which interpolation points \( \{t_M\}_{M \leq 2} \) and basis functions \( \{q_M\}_{M \leq 2} \) are computed. The next \( t_M \) and \( q_M \) are given by

\[
  t_M = \operatorname{arg sup}_{x \in \Omega} |r_M(x)|, \quad q_M(x) = \frac{r_M(x)}{r_M(t_M)}
\]
We are now ready to apply EIM on the jacobian $j$ the affine decomposition reads
\[
j(u,v; \mu; k_u; \{w_i(u(\mu), x; \mu)\}_i) = \sum_{q=1}^{Q_{eim}^{\mu}} \sum_{m=1}^{M_j^q} \gamma_{j,m}^q(k_u; \mu)j_{m}^q(u,v) + \sum_{l=1}^{Q_{eff}^{\mu}} \theta_{j,l}^q(k_u; \mu)j_{l}^q(u,v) \quad \forall u,v \in X, \forall \mu \in \mathcal{D},
\]

with $Q_{eim}^\mu$ (resp. $Q_{eff}^\mu$) the number of non-affinely (resp. affinely) parametrized terms of $j$, and $\gamma_{j,m}^q$ (resp. $j_{m}^q$) obtained from $\beta_{j,m}^q$ (resp. $q_{i,m}$). Similar decomposition is obtained for the residual $r$.

2.2. Reduced basis method

We now turn to the RB methodology. We introduce $S_N = \{\mu_1, \cdots, \mu_N\}$ with $N << N$, and we define the set of solutions $S_N^u = \{u_N(\mu_i)\}_{i=1}^N$ which are orthonormalized with respect to the $\langle, \rangle_N$ inner product to provide $W_N = \{\xi_i\}_{i=1}^N$.

The reduced basis approximation $u_N(\mu) \in W_N$ is expressed as a linear combination of $W_N$ elements
\[
u_N(\mu) = \sum_{i=1}^N u_{N,i}(\mu)\xi_i \quad \text{such that} \quad r(u_N, v; \mu; \{w_i(u_N, x; \mu)\}_i) = 0 \quad \forall v \in W_N
\]

The offline/online strategy used to build efficiently the reduced basis approximation is based on the affine decomposition (3),(9). Choosing $\{\xi_i\}_{i=1}^N$ as test functions and using (10) we have for $1 \leq l \leq N$
\[
\sum_{j=1}^N j(\xi_j, \xi_i; \mu; k_u; \{w_i(k_u, x; \mu)\}_i)j^{(k+1)u_N,j} - k_{N,j} = -r(\xi_i; \mu; k_u; \{w_i(k_u, x; \mu)\}_i)
\]

The offline step consists in the pre-computation of the terms $j^0(\xi_j, \xi_i)$, $j^1(\xi_j, \xi_i)$ and $r^0(\xi_i)$, $r^1(\xi_i)$, and is done offline once thanks to the affine decomposition. To evaluate online $k^{(k+1)u_N}(\mu)$ for any given $\mu$, the coefficients $\gamma_{j,m}^q(k_u, \mu), \theta_{j,l}^q(k_u, \mu)$ and $\gamma_{r,m}^q(k_u, \mu), \theta_{r,l}^q(k_u, \mu)$ are computed in order to recover the $N \times N$ system (10) giving $k^{(k+1)u_N}(\mu)$ coefficients and consequently $k^{(k+1)u_N}(\mu)$.

3. A Simultaneous EIM-RB method

The standard methodology described previously briefly requires the use of EIM prior to the RB methodology for each affine parameter dependent function $w_i$. These EIM approximations are built up front allowing to then write the affine decomposition (9). However the greedy algorithm (7) of the EIM offline step requires the computation of the solution $u_N(\mu)$ for all points of $\Xi \in \mathcal{D}$, i.e. in the step (7).

The SER methodology proposes to reduce the computational cost by simply using the readily available reduced basis approximation based on the previous EIM step and build simultaneously EIM and RB. In particular the expensive step (7) will now use solely RB approximations.

The initialization of EIM offline stage (6) doesn’t change since no reduced approximation $u_N(\mu)$ is available yet. The resulting rough EIM approximations $U_{i,1}$ are used to compute a first affine decomposition from which $\tilde{\xi}_1$ can be built, leading to a first reduced approximation $u_1(\mu)$. After this initialization step, EIM and RB approximation spaces are enriched alternatively. Each new EIM basis function $q_M$ is built from reduced basis approximation $U_{M-1}(\mu)$ obtained at previous iteration $M-1$ (ii) complete the EIM approximation to then build the affine decomposition for $U_{M}(\mu)$. To summarize, the EIM steps modified by SER now read
\[
\tilde{\mu}_{i,M} = \arg\max_{\mu \in \Xi} \inf_{z \in W_{M-1}} ||w_i(U_{M-1}(\mu); \cdots; \mu) - z||_{L^\infty(\Omega)}
\]

\[
\tilde{\xi}_{i,M} = w(U_{M-1}(\tilde{\mu}_{i,M}); x; \tilde{\mu}_{i,M}), \quad \hat{S}_{i,M} = \hat{S}_{i,M-1} \cup \{\tilde{\mu}_{i,M}\}, \quad \hat{W}_{i,M} = \hat{W}_{i,M-1} \oplus \text{span}(\tilde{\xi}_{i,M})
\]

The residual $r_{i,M}(\mu) = w_i(U_{M-1}(\tilde{\mu}_{i,M}); x; \tilde{\mu}_{i,M}) - w_i(U_{M-1}(\tilde{\mu}_{i,M}); x; \tilde{\mu}_{i,M})$ then gives $t_{i,M}$ and $q_{i,M}$
\[
t_{i,M} = \arg\sup_{x \in \Omega} |r_{i,M}(x)|, \quad q_{i,M}(x) = \frac{r_{i,M}(x)}{r_{i,M}(t_{i,M})}
\]

The affine decomposition is then updated with the new EIM approximation $w_{i,M}$, to compute the next reduced basis $\xi_M$ (i.e) thanks to (11) to then enrich $W_N$ space.
Remark 1 (RB updates). The EIM approximations are changing during the build of $W_N$ space. Then, the operator – and the solved problem – evolves at each step, which can mildly deteriorate the approximation. Recomputing $W_N$ elements using finite element solves based on the current EIM approximation may be considered. The offline precomputations need however to be updated for all elements of $W_N$ for each update of the affine decomposition.

Remark 2 (EIM updates). In the SER methodology only one finite element solve of (1) is required for the initialization afterwards the EIM and RB approximations are updated alternatively. We may in fact update the RB approximation every $r$ EIM steps: if $r = M$ we recover the standard method, if $r = 1$ we recover the SER method and if $1 < r < M$ we have an intermediary method which requires finite element solves for the intensive EIM step (7) before the first RB update. Other alternatives are readily available and some will be discussed in a future publication.

4. Preliminary results

We now turn to numerical experiments of the SER method compared to the standard one based on the benchmark problem introduced in [9]. It reads, find $u$ such that

$$-\Delta u + \mu_1 e^{\mu_2 u} - \frac{1}{\mu_2} = 100 \sin(2\pi x)\sin(2\pi y) \quad \text{in} \quad \Omega = [0,1]^2 \quad \text{and} \quad \mu = (\mu_1, \mu_2) \in \mathcal{D} = [0.01, 10]^2$$

and we are interested in the output $s$, the average of the solution $u$ over $\Omega$. Thanks to the function $g(u,x;\mu) = \mu_1 e^{\mu_2 u}$ we are in the setting of the SER methodology for non-linear problems. Following the standard methodology we develop $g_M = \sum_{i=1}^{M} \beta_i^M(u, \mu) q_i(x)$ of $g$ thanks to the Empirical Interpolation Method (see section 2.1).

We shall use the absolute errors on the solution and the output, defined as follows

$$\epsilon_{u,M,N}^r = \| u_N - u_N^r \|_{L_2} \quad \epsilon_{s,M,N}^r = | s_N - s_N^r |$$

where $u_N^r$ is the finite element solution/output of the initial problem (2), $s_N^r$ the reduced basis solution/output while $r$ is the frequency at which the EIM are updated, see remark 2.

We first display the maximum of the absolute errors (16) using the standard method $r = M$ in table 1a which reproduces the results in [9]. Tables 1c and 1d correspond to the SER methodology ($r = 1$) with $N = M$ and investigate the influence of $W_N$ recomputation in SER method, see remark 1. Table 1b is an intermediary stage such that $1 < r < M$ where the EIM basis functions are built by groups of $r$ ($r = 5$). In this last case, since we do not have access yet to the RB, the first group of $r$ EIM basis is built from finite element approximations and reduced basis approximations are used afterwards. This explains, for example, that $(N = 4, M = 5)$ is similar to the first one in table 1a.

The maximum of the errors observed with SER method ($r = 1$) is slightly higher than with the case $r = 5$ which itself displays results slightly higher than the standard method $r = M$. This behavior is expected. The results show the pertinence of the SER method and that we can expect good results within a reasonable computational budget, since the number of finite element approximations can then be reduced to $N + 1$ (table 1d).

Conclusion

We have now an algorithm and variants that allow an efficient use of EIM and RB in the context of non-linear non-affine partial differential equations. We have already deployed SER in real applications and the initial results are very promising showing the same behavior as the benchmark problem of this paper. This will be reported as well as an analysis of SER in a subsequent paper with applications to non-linear multiphysics problems.
