## Abstract

In this paper nonparametric wavelet estimators of the quantile density function are proposed. Consistency of the wavelet estimators is established under the  $\mathbb{L}_p$  risk. A simulation study illustrates the good performance of our estimators.

*Keywords:* Quantile Density Estimation, Rates of convergence, Wavelet methods

*2010 MSC:* 62G07, 62G20

---

## 1. Introduction

**Motivation.** Quantile density function, the derivative of the quantile function, comes up in the study of lifetime and survival data. The expression for the limiting variance of empirical and kernel type estimators of the quantile function involves the quantile density function. The hazard  
5 quantile function too can be written in terms of the quantile density function. Nonparametric estimators of the quantile density function have been studied by [33], [23] and [45]. Most of these estimators underperform at the tails, see, for example, [45]. Hence there is a need to look at alternate estimators.

**On the quantile function.** Quantiles are often used for statistical modeling and analysis

10 of data. Measures based on quantiles are less influenced by outliers. Hence they are particularly useful in the study of lifetime data and also for studying heavy tailed distributions. Sometimes the distribution function of the random variable of interest can not be expressed in a closed form. However, the quantile function can be written in an explicit form, for example, Generalized Lambda distribution (GLD) and Skew logistic distribution (see [20] and [24]).

15 Researchers have used quantiles for preliminary data analysis. Statistical analysis of data based on quantile functions has been carried out in reliability and survival analysis and other branches of applied statistics (see, for example, [37], [44], [48], [30], [31], [39] and [41]). [46, 47] have developed multiple comparison procedures for quantile functions. Nonparametric test procedures under competing risks have been developed by [34], [22] and [40].

20 Let  $X$  be a continuous random variable with cumulative distribution function  $F(x)$ , density function  $f(x)$  and hazard function  $r(x)$ . The quantile function of  $X$  is defined as

$$Q(x) = F^{-1}(x) = \inf\{y \in R; F(y) \geq x\}, \quad x \in [0, 1]. \quad (1.1)$$

It satisfies

$$F(Q(x)) = x. \quad (1.2)$$

[32] and [23] defined the quantile density function corresponding to quantile function  $Q(x)$  by

$$g(x) = Q'(x) = \frac{1}{f(Q(x))}, \quad x \in [0, 1]. \quad (1.3)$$

Note that the sum of two quantile density functions is again a quantile density function. This idea is useful in modeling data. [31] defined the hazard quantile function  $R(x)$  as follows :

$$R(x) = r(Q(x)) = \frac{f(Q(x))}{1 - F(Q(x))} = \frac{1}{(1 - x)g(x)}, \quad x \in (0, 1).$$

Hence a nonparametric estimator of the quantile density function will give us an estimator of the  
25 hazard quantile function.

**Overview of previous works.** Let  $X_1, X_2, \dots, X_n$  be *iid* random variables from distribution  $F(x)$  defined on a probability space  $(\Omega, \mathcal{A}, \mathbb{P})$ . [23] suggested the following two smooth estimators of the quantile density function. The first one, denoted by  $\hat{g}_{j1}(x)$ , is given by

$$\hat{g}_{j1}(x) = \frac{1}{\hat{f}(\hat{Q}(x))}, \quad x \in [0, 1], \quad (1.4)$$

where  $\hat{f}(x)$  is a kernel type density estimator of the form :

$$\hat{f}(x) = \frac{1}{nh(n)} \sum_{i=1}^n K\left(\frac{x - X_i}{h(n)}\right),$$

where  $h(n)$  is the bandwidth and  $K(\cdot)$  an appropriate kernel function, and  $\hat{Q}(x)$  is the usual empirical estimator of  $Q(x)$ . The properties that the kernel function and the bandwidth need to satisfy have been listed in [45].

The second estimator of [23] is given as

$$\hat{g}_{j2}(x) = \sum_{i=2}^n X_{(i)} \left( K_{h(n)}\left(x - \frac{i-1}{n}\right) - K_{h(n)}\left(x - \frac{i}{n}\right) \right), \quad x \in [0, 1], \quad (1.5)$$

where  $X_{(i)}$  is the  $i^{\text{th}}$  order statistic,  $i = 1, 2, \dots, n$ , and  $K_h(u) = (1/h)K(u/h)$ .

[23] and [45] showed that the performance of the estimator of  $g(x)$  given by (1.4) is better than that of the estimator given by (1.5).

[45] proposed the following smooth estimator of the quantile density function :

$$\hat{g}_S(x) = \frac{1}{h(n)} \int_0^1 K\left(\frac{t-x}{h(n)}\right) \frac{1}{\hat{f}(\hat{Q}(t))} dt, \quad x \in [0, 1], \quad (1.6)$$

where  $K(\cdot)$  is a kernel and  $h(n)$  is the bandwidth sequence. It can also be expressed as

$$\hat{g}_S(x) = \frac{1}{nh(n)} \sum_{i=1}^n K\left(\frac{S_i - x}{h(n)}\right) \frac{1}{\hat{f}(X_{(i)})}.$$

where  $S_i$  is the proportion of observations less than or equal to  $X_{(i)}$ , the  $i^{\text{th}}$  order statistic.

**Contributions.** In this paper, we explore a different approach by considering estimators based on projections on a wavelet basis of the (crude) form :

$$\hat{g}(x) = \sum_m \hat{a}_m e_m(x), \quad x \in [0, 1],$$

where  $\hat{a}_m$  denotes an estimator of the coefficient  $a_m = \int g(x)e_m(x)dx$  and  $\{e_m\}$  forms the wavelet basis. Such basis is of interest, thanks to its localization in space and frequency properties. For the standard nonparametric estimation problems in density, regression, ... wavelet estimators outperform kernel estimators in representing discontinuities (edges, spikes, ...). Basics on wavelet estimation can be found in [21].

In this study, we develop two kinds of wavelet estimators for the quantile density function  $g$  : a linear one based on simple projections and a nonlinear one based on a hard thresholding rule. Our

wavelet hard thresholding estimator has the feature to be adaptive according to  $g(x)$ . Let us mention  
 45 that, due to the choice of  $\hat{a}_m$  considered, our estimators belong to the family of warped wavelet  
 basis estimators introduced by [26] in another statistical context - regression problem with random  
 design. Under some smoothness assumptions on  $g(x)$ , we determine fast rates of convergence of the  
 proposed estimators under the  $\mathbb{L}_p$  risk.

**Paper organization.** The rest of this paper is organized as follows. In the next section, we  
 50 present our wavelet estimators. The main theoretical results are described in Section 3 and Section  
 4 is devoted to the numerical performances of our estimators. The proofs of the technical results  
 appear in Sections 5.

## 2. Wavelet estimators

**Wavelet expansion.** We define the spaces  $\mathbb{L}_p([0, 1])$ ,  $p \geq 1$ , by

$$\mathbb{L}_p([0, 1]) = \left\{ h : [0, 1] \rightarrow R; \int_{[0,1]} |h(x)|^p dx < \infty \right\}.$$

For the purpose of the paper, we consider an orthonormal wavelet basis of  $\mathbb{L}_2([0, 1])$  associated  
 55 with the initial wavelet functions  $\phi$  and  $\psi$  of the Daubechies wavelets  $db2N$ , where  $N$  denotes a  
 positive integer. The functions  $\phi$  and  $\psi$  are compactly supported and continuously differentiable.

For any  $x \in R$ ,

$$\phi_{j,k}(x) = 2^{j/2} \phi(2^j x - k), \quad \psi_{j,k}(x) = 2^{j/2} \psi(2^j x - k).$$

Then, with an appropriate treatment at the boundaries, there exists an integer  $\tau$  satisfying  $2^\tau \geq 2N$   
 such that, for any  $\ell \geq \tau$ , the system

$$\mathcal{W} = \{\phi_{\ell,k}; k \in \{0, \dots, 2^\ell - 1\}; \psi_{j,k}; k \in \{0, \dots, 2^j - 1\}, j \geq \ell\}$$

is an orthonormal basis of  $\mathbb{L}_2([0, 1])$ .

For convenience, we suppose that  $X_1$  is compactly supported, say  $X_1(\Omega) = [0, 1]$ , and that  $F$  is  
 continuous and strictly monotone from  $[0, 1]$  to  $[0, 1]$ .

Let us suppose that  $g \in \mathbb{L}_2([0, 1])$ . Hence, for any integer  $\ell \geq \tau$ , we have the following wavelet  
 expansion on  $\mathcal{W}$  :

$$g(x) = \sum_{k=0}^{2^\ell-1} c_{\ell,k} \phi_{\ell,k}(x) + \sum_{j=\ell}^{\infty} \sum_{k=0}^{2^j-1} d_{j,k} \psi_{j,k}(x), \quad x \in [0, 1],$$

60 where

$$c_{j,k} = \int_{[0,1]} g(x)\phi_{j,k}(x)dx, \quad d_{j,k} = \int_{[0,1]} g(x)\psi_{j,k}(x)dx. \quad (2.1)$$

All the technical details can be found in, e.g., [11] and [27].

**Wavelet coefficients estimators.** The wavelet coefficients  $c_{j,k}$  and  $d_{j,k}$  are unknown and need to be estimated. Our approach is based on the following remark : by the change of variable  
 65  $x = F(y)$  with  $y \in X_1(\Omega) = [0, 1]$ , we can rewrite  $c_{j,k}$  as

$$\begin{aligned} c_{j,k} &= \int_{[0,1]} g(x)\phi_{j,k}(x)dx = \int_{[0,1]} \frac{1}{f(Q(x))} \phi_{j,k}(x)dx \\ &= \int_{[0,1]} \phi_{j,k}(F(x))dx. \end{aligned} \quad (2.2)$$

Similarly

$$d_{j,k} = \int_{[0,1]} \psi_{j,k}(F(x))dx. \quad (2.3)$$

Since  $F$  is unknown, we estimate it by the empirical estimator :

$$\hat{F}(x) = \frac{1}{n} \sum_{i=1}^n \mathbf{1}_{\{X_i \leq x\}}, \quad x \in [0, 1],$$

where  $\mathbf{1}$  is the indicator function.

This leads to the following integral estimator for  $c_{j,k}$  :

$$\hat{c}_{j,k} = \int_{[0,1]} \phi_{j,k}(\hat{F}(x))dx. \quad (2.4)$$

The analogous estimator for  $d_{j,k}$  is

$$\hat{d}_{j,k} = \int_{[0,1]} \psi_{j,k}(\hat{F}(x))dx. \quad (2.5)$$

70 Due to the composition of the element of the wavelet basis with  $\hat{F}(x)$ ,  $\hat{c}_{j,k}$  and  $\hat{d}_{j,k}$  can be viewed as warped wavelet basis coefficient estimators. Such estimators were introduced by [26] in the context of regression with random design. Other improvements and modern developments can be found in [5, 6] for the same regression model and in [7] for the relative density estimation problem (with trigonometric basis).

75 **Remark 2.1.** Clearly,  $\hat{c}_{j,k}$  and  $\hat{d}_{j,k}$  are not unbiased estimators for  $c_{j,k}$  and  $d_{j,k}$ . However, using the dominated convergence theorem, one can prove that they are asymptotically unbiased. Moreover, they satisfy power moments and concentration inequalities. See Lemmas 5.1, 5.2, 5.3 and 5.4 below.

**Remark 2.2.** Our study can be extended for  $X_1(\Omega) = [a, b]$  with  $a < b$  finite. Using the change of variables  $x = F(y)$  with  $y \in X_1(\Omega) = [a, b]$ , we get

$$c_{j,k} = \int_{[0,1]} g(x)\phi_{j,k}(x)dx = \int_{[a,b]} \phi_{j,k}(F(x))dx.$$

80 So we consider the last integral over  $[a, b]$  instead of  $[0, 1]$ .

Based on  $\hat{c}_{j,k}$  and  $\hat{d}_{j,k}$  given in (2.4) and (2.5), respectively, we consider two kinds of wavelet estimators for  $g(x)$  : a linear wavelet estimator  $\hat{g}_L(x)$  and a hard thresholding wavelet estimator  $\hat{g}_H(x)$ , both defined below.

85 **Linear wavelet estimator.** We define the linear wavelet estimator  $\hat{g}_L(x)$  by

$$\hat{g}_L(x) = \sum_{k=0}^{2^{j_0}-1} \hat{c}_{j_0,k} \phi_{j_0,k}(x), \quad x \in [0, 1], \quad (2.6)$$

where  $j_0$  is a positive integer chosen a posteriori (see Theorems 3.1 and 3.3).

**Hard thresholding wavelet estimator.** We define the hard thresholding wavelet estimator  $\hat{g}_H(x)$  by

$$\hat{g}_H(x) = \sum_{k=0}^{2^\tau-1} \hat{c}_{\tau,k} \phi_{\tau,k}(x) + \sum_{j=\tau}^{j_1} \sum_{k=0}^{2^j-1} \hat{d}_{j,k} \mathbf{1}_{\{|\hat{d}_{j,k}| \geq \lambda_j\}} \psi_{j,k}(x), \quad x \in [0, 1], \quad (2.7)$$

90 where  $\hat{c}_{j,k}$  and  $\hat{d}_{j,k}$  are defined by (2.4) and (2.5),  $j_1$  is a positive integer and  $\lambda_j$  represents a threshold. Both  $j_1$  and  $\lambda_j$  will be chosen a posteriori (see Theorems 3.2 and 3.4)

The construction of  $\hat{g}_H(x)$  exploits the sparse nature of the wavelet decomposition of  $g(x)$  : only the wavelet coefficients  $d_{j,k}$  with large magnitude contain the main information (in terms of details) of  $g$ . Hence  $\hat{g}_H(x)$  aims to estimate only the larger coefficients and remove the other (or estimate it by 0). Further aspects and explanation related to this selection techniques can be found in [3],  
95 [21] and [50].

As usual in wavelet estimation, we will suppose that the unknown function  $g(x)$  belongs to Besov balls defined below.

100 **Besov balls.** Let  $M > 0$ ,  $s > 0$ ,  $r \geq 1$  and  $q \geq 1$ . We say that  $g(x)$  belongs to the Besov ball  $B_{r,q}^s(M)$  if there exists a constant  $M^* > 0$  (depending on  $M$ ) such that (2.1) satisfy

$$\left( \sum_{k=0}^{2^\tau-1} |c_{\tau,k}|^r \right)^{1/r} + \left( \sum_{j=\tau}^{\infty} \left( 2^{j(s+1/2-1/r)} \left( \sum_{k=0}^{2^j-1} |d_{j,k}|^r \right)^{1/r} \right)^q \right)^{1/q} \leq M^*,$$

with the usual modifications if  $r = \infty$  or  $q = \infty$ .

In this expression,  $s$  is a smoothness parameter and  $r$  and  $q$  are norm parameters. Details on Besov balls can be found in [29] and [21, Chapter 9].

### 105 3. Theoretical results

#### 3.1. First results

This section is devoted to the study of performance of wavelet estimators  $\hat{g}_L(x)$  and  $\hat{g}_H(x)$ .

Theorem 3.1 determines the rates of convergence attained by  $\hat{g}_L(x)$  under the  $\mathbb{L}_p$ -risk over Besov balls.

**Theorem 3.1.** *Let  $p \geq 1$ . Assume that  $g \in \mathbb{L}_{\max(r,2)}([0,1]) \cap B_{r,q}^s(M)$  with  $s > 1/r$ ,  $r \geq 1$  and  $q \geq 1$ . Set  $s_* = \min(s, s - 1/r + 1/p)$  and let  $\hat{g}_L(x)$  be as in (2.6) with  $j_0$  being the integer such that*

$$n^{1/(2s_*+4)} < 2^{j_0+1} \leq 2n^{1/(2s_*+4)}.$$

*Then there exists a constant  $C > 0$  such that*

$$\mathbb{E} \left( \int_{[0,1]} |\hat{g}_L(x) - g(x)|^p dx \right) \leq C n^{-s_*p/(2s_*+4)}.$$

110 The proof is based on statistical properties of  $\hat{c}_{j,k}$  and  $\hat{d}_{j,k}$  (see Lemmas 5.1 and 5.2), and technical bounds related to wavelet series and the  $\mathbb{L}_p$  norm. At this stage, let us consider the rate of convergence  $n^{-s_*p/(2s_*+4)}$  as a benchmark. This aspect will be discussed later.

Theorem 3.2 explores the rates of convergence of  $\hat{g}_H(x)$  under the  $\mathbb{L}_p$ -risk over Besov balls.

**Theorem 3.2.** Let  $p \geq 1$  and  $\hat{g}_H$  be as in (2.7) with  $j_1$  being the integer satisfying

$$\left(\frac{n}{\ln(n)}\right)^{1/4} < 2^{j_1+1} \leq 2 \left(\frac{n}{\ln(n)}\right)^{1/4},$$

and  $\lambda_j$  being the threshold :

$$\lambda_j = K 2^{3j/2} \sqrt{2p} \sqrt{\frac{\ln(n)}{n}}, \quad (3.1)$$

115 with  $K = \sup_{x \in [0,1]} |\psi'(x)|$ .

Suppose that  $g \in \mathbb{L}_{\max(r,2)}([0,1]) \cap B_{r,q}^s(M)$  with  $s > 1/r$ ,  $r \geq 1$  and  $q \geq 1$ . Then there exists a constant  $C > 0$  such that

$$\mathbb{E} \left( \int_{[0,1]} |\hat{g}_H(x) - g(x)|^p dx \right) \leq C \varphi_n,$$

where

$$\varphi_n = \begin{cases} \left(\frac{\ln(n)}{n}\right)^{sp/(2s+4)}, & \text{for } rs > 2(p-r), \\ \left(\frac{\ln(n)}{n}\right)^{(s-1/r+1/p)p/(2s-2/r+4)}, & \text{for } rs < 2(p-r), \\ \left(\frac{\ln(n)}{n}\right)^{(s-1/r+1/p)p/(2s-2/r+4)} (\ln(n))^{(p-r/q)+}, & \text{for } rs = 2(p-r). \end{cases}$$

The proof is based on statistical properties of  $\hat{c}_{j,k}$  and  $\hat{d}_{j,k}$  (see Lemmas 5.3 and 5.4), and a general result on the  $\mathbb{L}_p$  risk of the hard thresholding wavelet estimator which can be proved by combining Theorem 5.1 of [25] and Theorem 4.2 of [8].

120 If we do a global comparison between the results of Theorems 3.1 and 3.2, the rates of convergence achieved by  $\hat{g}_H(x)$  are better than the one achieved by  $\hat{g}_L(x)$ . Moreover, let us recall that  $\hat{g}_H(x)$  is adaptive while  $\hat{g}_L(x)$  is not adaptive due to its dependence on  $s$  in its construction.

In comparison to the standard density estimation problem, the rates of convergence obtained in Theorems 3.1 and 3.2 are slower. To be more specific,

- 125
- for the wavelet linear estimation, the standard rate of convergence is  $n^{-s_*p/(2s_*+1)}$ , against  $n^{-s_*p/(2s_*+4)}$  in Theorem 3.1 (see [21, Section 10.2]).
  - for the wavelet nonlinear estimation, the standard rate of convergence is similar to  $\varphi_n$  but with "+1" instead of "+4" in the exponent (see [13]).

130 The rest of the study proves that, under an additional assumption on  $g(x)$ , the rates of convergence obtained above can be improved and be made equal to the standard one.

### 3.2. Improved results but with an additional assumption

We now introduce the following Lipschitz(1/2) assumption :

**(A)** there exists a constant  $C_* > 0$  such that, for any  $(x, y) \in [0, 1]^2$ ,

$$|g(x) - g(y)| \leq C_* \sqrt{|x - y|}.$$

Theorems 3.3 and 3.4 below show that, under **(A)**, one can construct more efficient linear and hard thresholding wavelet estimators than those presented in Theorems 3.1 and 3.2.

**Theorem 3.3.** *Let  $p \geq 1$ . Suppose that **(A)** is satisfied and  $g \in B_{r,q}^s(M)$  with  $s > 1/r$ ,  $r \geq 1$  and  $q \geq 1$  such that  $\min(s, s - 1/r + 1/p) > 1/2$ . Set  $s_* = \min(s, s - 1/r + 1/p)$  and  $\hat{g}_L(x)$  be as in (2.6) with  $j_0$  being the integer such that*

$$n^{1/(2s_*+1)} < 2^{j_0+1} \leq 2n^{1/(2s_*+1)}.$$

Then there exists a constant  $C > 0$  such that

$$\mathbb{E} \left( \int_{[0,1]} |\hat{g}_L(x) - g(x)|^p dx \right) \leq C n^{-s_* p / (2s_* + 1)}.$$

135

The proof is similar to the one of Theorem 3.1. The techniques involved in the proof make use of statistical results on  $\hat{c}_{j,k}$  and  $\hat{d}_{j,k}$  derived by [26] for the estimation of the regression function . These statistical results justify the consideration of **(A)** and a restriction on  $j_0$ , i.e.,  $2^{j_0} \leq \sqrt{n/\ln(n)}$ .

**Theorem 3.4.** *Let  $p \geq 1$ . Suppose that **(A)** is satisfied. Let  $\hat{g}_H(x)$  be (2.7) with  $j_1$  being the integer satisfying*

$$\sqrt{\frac{n}{\ln(n)}} < 2^{j_1+1} \leq 2\sqrt{\frac{n}{\ln(n)}},$$

and  $\lambda_j$  being the threshold :

$$\lambda_j = \kappa \sqrt{\frac{\ln(n)}{n}}, \tag{3.2}$$

where  $\kappa$  is a large enough constant (depending, among other, on  $C_*$  and  $\psi$ ). Suppose that  $g \in B_{r,q}^s(M)$  with  $s > 1/r$ ,  $r \geq 1$  and  $q \geq 1$ . Then there exists a constant  $C > 0$  such that

$$\mathbb{E} \left( \int_{[0,1]} |\hat{g}_H(x) - g(x)|^p dx \right) \leq C \Psi_n,$$

where

$$\Psi_n = \begin{cases} \left(\frac{\ln(n)}{n}\right)^{sp/(2s+1)}, & \text{for } 2rs > (p-r), \\ \left(\frac{\ln(n)}{n}\right)^{(s-1/r+1/p)p/(2s-2/r+1)}, & \text{for } (r, s, p) \in \mathcal{D}, \end{cases}$$

140 where  $\mathcal{D} = \{(r, s, q) \in [1, \infty) \times (1/r, \infty) \times [1, \infty); 1/2 + 1/r \leq s \leq (p-r)/(2r), r \leq (p-2)/(2(s-1/r) + 1)\}$ .

The proof uses arguments similar to those in Theorem 3.2. Again, the main originality is the use of new statistical results on  $\hat{c}_{j,k}$  and  $\hat{d}_{j,k}$  derived from the results proved by [26].

Let us remark that  $\Psi_n$  corresponds to the standard rate of convergence for the standard density  
145 estimation problem via the hard thresholding wavelet method (see [13]).

The next section explores the numerical performances of our wavelet estimators and compares them with the estimators developed by [23] and [45].

#### 4. Simulation Study

We consider the Beta distribution and the Generalized Lambda Distributions (GLD). It is  
150 easy to see that when parameters in Beta distribution were chosen from  $(0, 1)$ , the corresponding quantile density function satisfies all the conditions required to prove the results. On the other hand GLD has four different parameters, *i.e.*,  $\lambda_1, \lambda_2, \lambda_3$  and  $\lambda_4$ . The parameters  $\lambda_1$  and  $\lambda_2$  are, respectively, location and scale parameters, while  $\lambda_3$  and  $\lambda_4$  determine the skewness and kurtosis of the  $\text{GLD}(\lambda_1, \lambda_2, \lambda_3, \lambda_4)$ , see [24]. [19, Section 3] noted that GLD is very rich in the variety  
155 of density and tail shapes. It contains unimodal, U-shaped, J-shaped and monotone probability density functions. These can be symmetric or asymmetric and their tails can be smooth, abrupt, or truncated, and long, medium or short depending on the choice of parameters. [24, page 43] showed that when  $\lambda_3 > 0$  and  $\lambda_4 > 0$  the support of GLD is  $[\lambda_1 - 1/\lambda_2, \lambda_1 + 1/\lambda_2]$ . On the other hand, it is easy to see from the closed form of the quantile function of GLD that when  $\lambda_3 > 1$  and  $\lambda_4 > 1$ ,  
160 we have  $g \in \mathbb{L}_2([0, 1])$ .

We consider performance of linear wavelet estimator  $\hat{g}_L(x)$  and the hard thresholding wavelet estimator  $\hat{g}_H(x)$  presented in Section 2 and compare them with a linear wavelet estimator after local linear smoothing  $\hat{g}_{LS}(x)$  proposed by [36]. The new smooth linear wavelet estimator has been adapted from [17, 18]. [1, 2], [9, 10] and [42, 43] have proposed this version of wavelet estimators

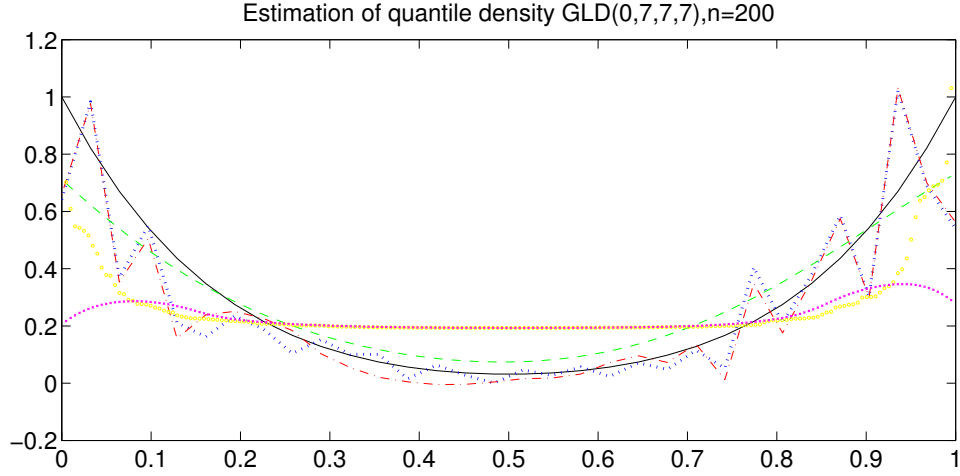

Figure 1: Estimation of quantile density. The black curve is the true GLD, the blue dotted line is linear wavelet estimator,  $\hat{g}_L(x)$ , the red dashed dot line is threshold wavelet estimator,  $\hat{g}_H(x)$ , the green dashed line is smooth version of our estimator,  $\hat{g}_{LS}(x)$ , the yellow line with circles is Jones' estimator,  $\hat{g}_{j1}(x)$ , and the magenta line with crosses is  $\hat{g}_S(x)$ .

165 and showed that it performs better than  $\hat{g}_L(x)$  in different applications. Let us mention that it depends on a bandwidth  $h(n)$  (equal to 0.15 if there is no mention). Integrals in wavelet coefficient estimators introduced in (2.4) and (2.5) have been approximated by Simpson's rule. Coarsest level,  $j_0$ , is chosen as 5. The parameters  $j_1$  and  $\lambda_j$  are as given in Theorem 3.4 (according to the value of  $n$ ). Following [36], the constant  $\kappa$  of threshold is chosen as a scaled absolute median of  
 170 empirical wavelet coefficients. We employ Daubechies-Lagarias algorithm and write the codes in Matlab which are adapted from [36]. We compare these three estimators with  $\hat{g}_{j1}(x)$  and  $\hat{g}_S(x)$ , two estimators given in (1.4) and (1.6), respectively. Following [45], the kernel function chosen is Triangular,  $K(x) = (1 - |x|)\mathbf{1}_{\{|x| \leq 1\}}$  and  $h(n) = 0.15$  if there is no mention.

Figures 1, 2 and 3 show the results of simulation for the Generalized Lambda Distributions  
 175 : GLD(0,7,7,7), GLD(0.5,1,2,6) and the Beta distribution - Beta (0.5, 0.5), respectively. In each figure, the black curve is the true quantile density function, the blue dotted line is linear wavelet estimator  $\hat{g}_L(x)$ , the red dashed dot line is threshold wavelet estimator  $\hat{g}_H(x)$ , the green dashed line is smooth version of our estimator  $\hat{g}_{LS}(x)$ , the yellow line with circles is Jones' estimator  $\hat{g}_{j1}(x)$  and the magenta line with crosses is Soni-Dewan-Jain's estimator  $\hat{g}_S(x)$ . From these three figures  
 180 we conclude that the smooth version of the proposed wavelet estimators is closer to the unknown

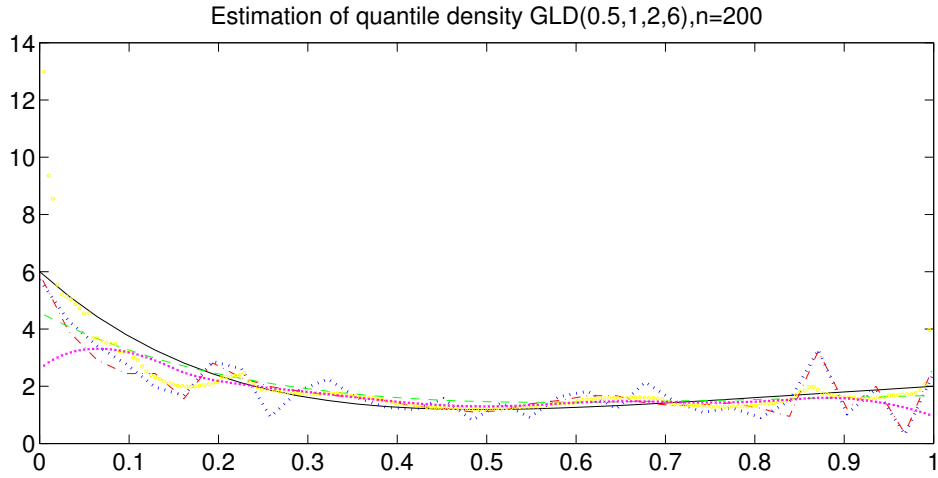

Figure 2: Estimation of quantile density. The black curve is the true GLD, the blue dotted line is linear wavelet estimator,  $\hat{g}_L(x)$ , the red dashed dot line is threshold wavelet estimator,  $\hat{g}_H(x)$ , the green dashed line is smooth version of our estimator,  $\hat{g}_{LS}(x)$ , the yellow line with circles is Jones' estimator,  $\hat{g}_{j1}(x)$ , and the magenta line with crosses is  $\hat{g}_S(x)$ .

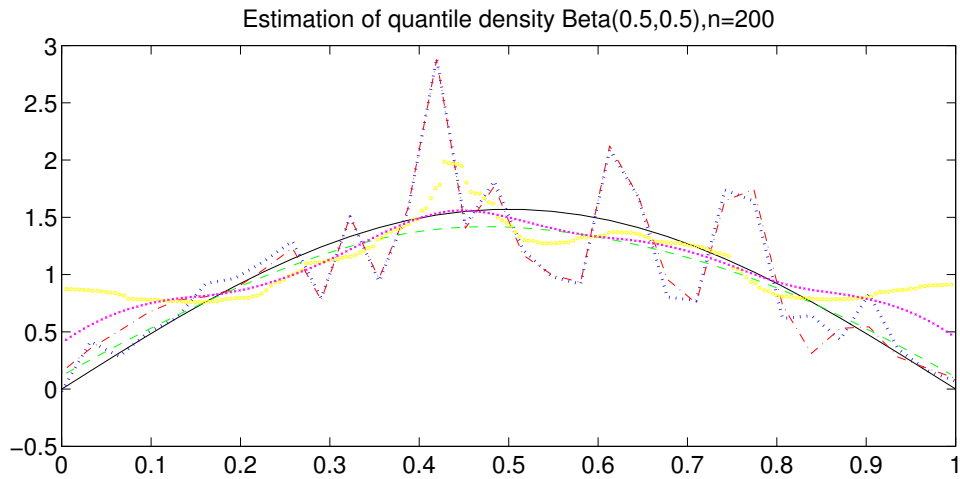

Figure 3: Estimation of quantile density. The black curve is the true Beta (0.5,0.5), the blue dotted line is linear wavelet estimator,  $\hat{g}_L(x)$ , the red dashed dot line is threshold wavelet estimator,  $\hat{g}_H(x)$ , the green dashed line is smooth version of our estimator,  $\hat{g}_{LS}(x)$ , the yellow line with circles is Jones' estimator,  $\hat{g}_{j1}(x)$ , and the magenta line with crosses is  $\hat{g}_S(x)$ .

Table 1: MISE for different estimators based on 500 replications

Estimator	GLD(0,7,7,7)		GLD(0.5,2,1.5,1.5)		GLD(0.1.5,1.5,1.5)		GLD(0.5,1,2,6)		Beta(0.5,0.5)	
	n=200	n=500	n=200	n=500	n=200	n=500	n=200	n=500	n=200	n=500
$\hat{g}_{LS}(x)$	<b>0.0078</b>	<b>0.0067</b>	<b>0.0101</b>	<b>0.0050</b>	<b>0.0189</b>	<b>0.0093</b>	<b>0.1149</b>	<b>0.0886</b>	<b>0.0252</b>	<b>0.0167</b>
$\hat{g}_{j1}(x)$	0.0268	0.0273	0.0648	0.0521	0.1088	0.0797	0.4718	0.2798	0.1259	0.1011
$\hat{g}_S(x)$	0.0512	0.0530	0.0127	0.0064	0.0256	0.0127	0.3758	0.3343	0.0604	0.0459

quantile density function as compared to the other four estimators we have studied.

Next we consider the mean integrated square error (MISE) of the smooth linear estimator of the quantile density function  $\hat{g}_{LS}(x)$ ,  $\hat{g}_{j1}(x)$  and  $\hat{g}_S(x)$  for Beta distributions (Beta (0.5, 0.5)) and Generalized Lambda Distributions (GLD) GLD(0,7,7,7), GLD(0.5,2,1.5,1.5), GLD(0,1.5,1.5,1.5) and GLD(0.5,1,2,6).

Table 1 shows the estimation of Mean Integrated Square Error (MISE) for GLDs for four different choices of parameters and Beta(0.5, 0.5). The results in this Table 1 are based on 500 replications and sample sizes  $n = 200$  and  $n = 500$ . We use the formula :

$$MISE = \frac{n-1}{500(n+1)^2} \sum_{i=1}^{500} \sum_{j=1}^n \left( \hat{f}_i \left( \frac{j}{n+1} \right) - f \left( \frac{j}{n+1} \right) \right)^2,$$

where  $\hat{f}_i$  is the quantile density estimator in  $i$ th replication and  $f$  is true quantile density function.

Tables 2, 3 and 4 show the Mean Square Error (MSE) for different choices of fixed  $x \in [0, 1]$  and different bandwidth parameters :  $h(n) = 0.15, 0.19, 0.25$ . We calculate the MSE of these estimators by generating 500 samples from GLD(0.5,1,2,6), Beta (0.5,0.5) and GLD(0,7,7,7), respectively. The sample size in each case is  $n = 200$ .

From Figures 1-3 and Tables 1-4 we conclude that

- (i) our wavelet based estimator performs well in estimation of unknown quantile density. The performance of smooth version of linear wavelet estimator works the best.
- (ii) our wavelet estimators perform well in the tails whereas [45] observed that the competitors

(1.4) and (1.6) suffer from boundary effect.

(iii) in majority of cases, the MSEs for the smooth version of the wavelet estimator are smaller than those of the competitors.

(iv) the MSEs and MISEs decrease as the sample size increases.

200 (v) the MSEs are bigger for  $x$  close to the tails.

(vi) the MISEs of smooth version of wavelet estimators are smaller than the MISEs of the competitors.

## 5. Proofs

### 5.1. Auxiliary results

The following lemmas show several statistical properties (moments and concentration inequalities) of the estimators  $\hat{c}_{j,k}$  and  $\hat{d}_{j,k}$  given in (2.4) and (2.5), respectively. The proofs or appropriate  
 210 references are given in the next sub-section.

**Lemma 5.1.** *Let  $p \geq 1$ ,  $\hat{c}_{j,k}$  be defined by (2.4) and  $\hat{d}_{j,k}$  be defined by (2.5). Then*

- *there exists a constant  $C > 0$  such that*

$$\mathbb{E}((\hat{c}_{j,k} - c_{j,k})^{2p}) \leq C 2^{3jp} \frac{1}{n^p}.$$

- *there exists a constant  $C > 0$  such that*

$$\mathbb{E}((\hat{d}_{j,k} - d_{j,k})^{2p}) \leq C 2^{3jp} \frac{1}{n^p}.$$

**Lemma 5.2.** *Let  $p \geq 1$ ,  $\hat{d}_{j,k}$  be defined by (2.5) and  $\lambda_j$  be defined by (3.1). Then*

$$\mathbb{P}\left(|\hat{d}_{j,k} - d_{j,k}| \geq \lambda_j\right) \leq 2 \frac{1}{n^p}.$$

215 **Lemma 5.3.** *Suppose that **(A)** is satisfied. Let  $p \geq 1$ ,  $j$  such that  $2^j \leq \sqrt{n/\ln(n)}$ ,  $\hat{c}_{j,k}$  be defined by (2.4) and  $\hat{d}_{j,k}$  be defined by (2.5). Then*

- *there exists a constant  $C > 0$  such that*

$$\mathbb{E}((\hat{c}_{j,k} - c_{j,k})^{2p}) \leq C \frac{1}{n^p}.$$

- *there exists a constant  $C > 0$  such that*

$$\mathbb{E}((\hat{d}_{j,k} - d_{j,k})^{2p}) \leq C \frac{1}{n^p}.$$

220 **Lemma 5.4.** *Suppose that **(A)** is satisfied. Let  $p \geq 1$ ,  $j$  such that  $2^j \leq \sqrt{n/\ln(n)}$ ,  $\hat{d}_{j,k}$  be defined by (2.5) and  $\lambda_j$  be defined by (3.2). Then*

$$\mathbb{P}\left(|\hat{d}_{j,k} - d_{j,k}| \geq \lambda_j\right) \leq 2 \frac{1}{n^p}.$$

In the rest of the paper, we use  $C$  to denote positive constants whose value may change from line to line.

5.2. Proofs of the auxiliary results

**Proof of Lemma 5.1.** Note that  $(\phi_{j,k}(x))' = 2^{3j/2}\phi'(2^jx - k)$  and  $K = \sup_{x \in [0,1]} |\phi'(x)| < \infty$ . The mean value theorem gives, for any  $(x, y) \in [0, 1]^2$ ,

$$|\phi_{j,k}(x) - \phi_{j,k}(y)| \leq 2^{3j/2}K|x - y|.$$

Therefore

$$\begin{aligned} |\hat{c}_{j,k} - c_{j,k}| &= \left| \int_{[0,1]} \left( \phi_{j,k}(\hat{F}(x)) - \phi_{j,k}(F(x)) \right) dx \right| \\ &\leq \int_{[0,1]} |\phi_{j,k}(\hat{F}(x)) - \phi_{j,k}(F(x))| dx \\ &\leq C2^{3j/2} \int_{[0,1]} |\hat{F}(x) - F(x)| dx. \end{aligned} \tag{5.1}$$

225 Using the Hölder inequality and the Fubini theorem, we have

$$\begin{aligned} \mathbb{E}((\hat{c}_{j,k} - c_{j,k})^{2p}) &\leq C2^{3jp} \mathbb{E} \left( \left( \int_{[0,1]} |\hat{F}(x) - F(x)| dx \right)^{2p} \right) \\ &\leq C2^{3jp} \left( \int_{[0,1]} \mathbb{E} \left( (\hat{F}(x) - F(x))^{2p} \right) dx \right). \end{aligned}$$

The Rosenthal inequality (see [38]) yields

$$\begin{aligned} &\mathbb{E} \left( (\hat{F}(x) - F(x))^{2p} \right) \\ &\leq C \left( \frac{(1 - F(x))^{2p}F(x) + (F(x))^{2p}(1 - F(x))}{n^{2p-1}} + \frac{(F(x)(1 - F(x)))^p}{n^p} \right) \\ &\leq C \frac{1}{n^p}. \end{aligned}$$

Hence

$$\mathbb{E}((\hat{c}_{j,k} - c_{j,k})^{2p}) \leq C2^{3jp} \frac{1}{n^p}.$$

Working with  $\psi$  instead of  $\phi$ , we show that

$$\mathbb{E}((\hat{d}_{j,k} - d_{j,k})^{2p}) \leq C2^{3jp} \frac{1}{n^p}.$$

The proof of Lemma 5.1 is complete. □

**Proof of Lemma 5.2.** By (5.1) with  $\psi$  instead of  $\phi$ , we obtain

$$\begin{aligned} |\hat{d}_{j,k} - d_{j,k}| &\leq K2^{3j/2} \int_{[0,1]} |\hat{F}(x) - F(x)| dx \\ &\leq K2^{3j/2} \sup_{x \in [0,1]} |\hat{F}(x) - F(x)|, \end{aligned}$$

with  $K = \sup_{x \in [0,1]} |\psi'(x)|$ . It follows from the Massart version of the Dvoretzky-Kiefer-Wolfowitz inequality (see [15] and [28]) and the definition of  $\lambda_j$  (3.1) that

$$\begin{aligned} &\mathbb{P} \left( |\hat{d}_{j,k} - d_{j,k}| \geq \frac{\lambda_j}{2} \right) \\ &\leq \mathbb{P} \left( K2^{3j/2} \sup_{x \in [0,1]} |\hat{F}(x) - F(x)| \geq \frac{1}{2} K2^{3j/2} \sqrt{2p} \sqrt{\frac{\ln(n)}{n}} \right) \\ &\leq \mathbb{P} \left( \sup_{x \in [0,1]} |\hat{F}(x) - F(x)| \geq \sqrt{\frac{p}{2}} \sqrt{\frac{\ln(n)}{n}} \right) \\ &\leq 2 \exp \left( -2n \left( \sqrt{\frac{p}{2}} \sqrt{\frac{\ln(n)}{n}} \right)^2 \right) = 2 \frac{1}{n^p}. \end{aligned}$$

This ends the proof of Lemma 5.2. □

**Proof of Lemmas 5.3 and 5.4.** By the change of variable  $x = Q(y)$ , let us observe that

$$\begin{aligned} \hat{d}_{j,k} - d_{j,k} &= \int_{[0,1]} \left( \psi_{j,k}(\hat{F}(x)) - \psi_{j,k}(F(x)) \right) dx \\ &= \int_{[0,1]} \left( \psi_{j,k}(\hat{U}(x)) - \psi_{j,k}(x) \right) g(x) dx, \end{aligned}$$

with

$$\hat{U}(x) = \frac{1}{n} \sum_{i=1}^n \mathbf{1}_{\{U_i \leq x\}}, \quad U_i = F(X_i).$$

235 Then the proofs of Lemmas 5.3 and 5.4 follow from the technical part of [26, Subsection 9.2.2. pages 1093 - 1098] with  $g$  instead of  $f(G^{-1})$ . Let us mention that for the validity of results we need to suppose **(A)** and a restriction on  $j$  is considered in our study, i.e.,  $2^j \leq \sqrt{n/\ln(n)}$ . □

### 5.3. Proofs of the main results

**Proof of Theorem 3.1.** We expand  $g$  on the wavelet basis  $\mathcal{W}$  as

$$g(x) = \sum_{k=0}^{2^{j_0}-1} c_{j_0,k} \phi_{j_0,k}(x) + \sum_{j=j_0}^{\infty} \sum_{k=0}^{2^j-1} d_{j,k} \psi_{j,k}(x),$$

where  $c_{j_0,k} = \int_{[0,1]} g(x)\phi_{j_0,k}(x)dx$  and  $d_{j,k} = \int_{[0,1]} g(x)\psi_{j,k}(x)dx$ . Hence

$$\hat{g}_L(x) - g(x) = \sum_{k=0}^{2^{j_0}-1} (\hat{c}_{j_0,k} - c_{j_0,k})\phi_{j_0,k}(x) - \sum_{j=j_0}^{\infty} \sum_{k=0}^{2^j-1} d_{j,k}\psi_{j,k}(x).$$

Using the inequality :  $|x + y|^p \leq 2^{p-1}(|x|^p + |y|^p)$ ,  $(x, y) \in \mathbb{R}^2$ , we obtain

$$\mathbb{E} \left( \int_{[0,1]} |\hat{g}_L(x) - g(x)|^p dx \right) \leq 2^{p-1}(F + G), \quad (5.2)$$

where

$$F = \mathbb{E} \left( \int_{[0,1]} \left| \sum_{k=0}^{2^{j_0}-1} (\hat{c}_{j_0,k} - c_{j_0,k})\phi_{j_0,k}(x) \right|^p dx \right)$$

and

$$G = \int_{[0,1]} \left| \sum_{j=j_0}^{\infty} \sum_{k=0}^{2^j-1} d_{j,k}\psi_{j,k}(x) \right|^p dx.$$

240 Using a  $\mathbb{L}_p$  norm result on wavelet series (see [21, Proposition 8.3]), the Cauchy-Schwarz inequality and Lemma 5.1, we obtain

$$\begin{aligned} F &\leq C2^{j_0(p/2-1)} \sum_{k=0}^{2^{j_0}-1} \mathbb{E} (|\hat{c}_{j_0,k} - c_{j_0,k}|^p) \\ &\leq C2^{j_0(p/2-1)} \sum_{k=0}^{2^{j_0}-1} (\mathbb{E} ((\hat{c}_{j_0,k} - c_{j_0,k})^{2p}))^{1/2} \\ &\leq C2^{j_0(p/2-1)} 2^{j_0} 2^{3j_0 p/2} \frac{1}{n^{p/2}} = C \left( \frac{2^{4j_0}}{n} \right)^{p/2}. \end{aligned} \quad (5.3)$$

On the other hand, using  $g \in B_{r,q}^s(M)$  and proceeding as in [14, eq. (24)], we have immediately

$$G \leq C2^{-j_0 s_* p}. \quad (5.4)$$

It follows from (5.2), (5.3), (5.4) and the definition of  $j_0$  that

$$\mathbb{E} \left( \int_{[0,1]} |\hat{g}_L(x) - g(x)|^p dx \right) \leq C \left( \left( \frac{2^{4j_0}}{n} \right)^{p/2} + 2^{-j_0 s_* p} \right) \leq Cn^{-s_* p / (2s_* + 4)}.$$

This ends the proof of Theorem 3.1.

245

□

**Proof of Theorem 3.2.** Theorem 3.2 is a consequence of Theorem 5.1 below with  $\nu = 3/2$  and Lemmas 5.1 and 5.2 above.

**Theorem 5.1.** Let  $h \in \mathbb{L}_2([0, 1])$  be an unknown function to be estimated from  $n$  observations and consider its wavelet decomposition. Let  $\hat{c}_{j,k}$  and  $\hat{d}_{j,k}$  be estimators of these wavelet coefficients  $c_{j,k}$  and  $d_{j,k}$  respectively. We suppose that there exist three constants  $\nu > 0$ ,  $C > 0$  and  $\kappa > 0$  such that the following inequalities hold :

**Moments inequalities :** for any  $j \geq \tau$  such that  $2^j \leq n$  and  $k \in \{0, \dots, 2^j - 1\}$ ,

$$\mathbb{E} \left( (\hat{c}_{j,k} - c_{j,k})^{2p} \right) \leq C 2^{2\nu j p} \left( \frac{\ln(n)}{n} \right)^p$$

and

$$\mathbb{E} \left( (\hat{d}_{j,k} - d_{j,k})^{2p} \right) \leq C 2^{2\nu j p} \left( \frac{\ln(n)}{n} \right)^p.$$

**Concentration inequality :** for any  $j \geq \tau$  such that  $2^j \leq n/\ln(n)$  and  $k \in \{0, \dots, 2^j - 1\}$ ,

$$\mathbb{P} \left( |\hat{d}_{j,k} - d_{j,k}| \geq \frac{\kappa}{2} 2^{\nu j} \sqrt{\frac{\ln(n)}{n}} \right) \leq C \left( \frac{\ln(n)}{n} \right)^p.$$

Let us define the hard thresholding wavelet estimator of  $h$  by

$$\hat{h}(x) = \sum_{k=0}^{2^\tau-1} \hat{c}_{\tau,k} \phi_{\tau,k}(x) + \sum_{j=\tau}^{j_1} \sum_{k=0}^{2^j-1} \hat{d}_{j,k} \mathbf{1}_{\left\{ |\hat{d}_{j,k}| \geq \kappa 2^{\nu j} \sqrt{\frac{\ln(n)}{n}} \right\}} \psi_{j,k}(x), \quad x \in [0, 1],$$

where  $j_1$  is the integer satisfying

$$\left( \frac{n}{\ln(n)} \right)^{1/(2\nu+1)} < 2^{j_1+1} \leq 2 \left( \frac{n}{\ln(n)} \right)^{1/(2\nu+1)}.$$

Suppose that  $h \in B_{r,q}^s(M)$  with  $s > 0$ ,  $r \geq 1$  and  $q \geq 1$ . Then there exists a constant  $C > 0$  such that

$$\mathbb{E} \left( \int_{[0,1]} |\hat{h}(x) - h(x)|^p dx \right) \leq C \Theta_{n,\nu},$$

where

$$\Theta_{n,\nu} = \begin{cases} \left( \frac{\ln(n)}{n} \right)^{sp/(2s+2\nu+1)}, & \text{for } rs > (\nu + 1/2)(p - r), \\ \left( \frac{\ln(n)}{n} \right)^{(s-1/r+1/p)p/(2s-2/r+2\nu+1)}, & \text{for } rs < (\nu + 1/2)(p - r), \\ \left( \frac{\ln(n)}{n} \right)^{(s-1/r+1/p)p/(2s-2/r+2\nu+1)} (\ln(n))^{(p-r/q)+}, & \text{for } rs = (\nu + 1/2)(p - r). \end{cases}$$

255 The general form of Theorem 5.1 can be proved using arguments similar to Theorem 5.1 of [25] for a bound of the  $\mathbb{L}_p$ -risk and Theorem 4.2 of [8] for the determination of the rates of convergence.

□

**Proof of Theorem 3.3.** The proof follows step by step the one of Theorem 3.1 with the use of Lemma 5.3 instead of Lemma 5.1. Thanks to the new definition of  $j_0$ , we finally obtain

$$\mathbb{E} \left( \int_{[0,1]} |\hat{g}_L(x) - g(x)|^p dx \right) \leq C \left( \left( \frac{2^{j_0}}{n} \right)^{p/2} + 2^{-j_0 s^* p} \right) \leq C n^{-s^* p / (2s^* + 1)}.$$

260

□

**Proof of Theorem 3.4.** The proof follows along the lines of that of Theorem 3.2 with the use of Lemmas 5.3 and 5.4 instead of Lemmas 5.1 and 5.2, and an adjustment on the rates of convergence as in [26, Proposition 2]. This minor modification is due to our definition of  $j_1$ .

□

265 **ACKNOWLEDGEMENTS** - We thank the associate editor and the referees for their critical comments which have led to the improved version of the paper.
