HAL is a multi-disciplinary open access archive for the deposit and dissemination of scientific research documents, whether they are published or not. The documents may come from teaching and research institutions in France or abroad, or from public or private research centers.

L’archive ouverte pluridisciplinaire HAL, est destinée au dépôt et à la diffusion de documents scientifiques de niveau recherche, publiés ou non, émanant des établissements d’enseignement et de recherche français ou étrangers, des laboratoires publics ou privés.
ABSTRACT

This paper describes our attempt to make the Hidden Markov Model (HMM) score following system developed at Ircam sensible to past experiences in order to obtain better audio to score real-time alignment for musical applications. A new observation modeling based on Gaussian Mixture Models is developed which is trainable using a learning algorithm we would call automatic discriminative training. The novelty of this system lies in the fact that this method, unlike classical methods for HMM training, is not concerned with modeling the music signal but with correctly choosing the sequence of music events that was performed. Besides obtaining better alignment, new system’s parameters are controllable in a physical manner and the training algorithm learns different styles of music performance as discussed.

1. INTRODUCTION

Score following is the real-time alignment of a known musical score to the audio signal produced by a musician playing this score. Score following has been studied for almost 20 years now. The goal is to simulate the behavior of a musician playing with another, a “synthetic performer,” to create a virtual accompanist that follows the score of the human musician. For an introduction and state of the art on score following and details of the the system developed by Ircam’s Real-Time Applications team, we refer the curious reader to [1] and Chapter 1 in [2]. In this paper, we introduce the learning algorithm used for Ircam’s score follower and its outcomes.

We begin this paper by a review of past attempts in score following literature, focusing on the adaptability and learning aspects of the algorithms, specially of importance for our work. This section is followed by an overview of our approach and objective towards training leading to a new observation modeling for score following. After reviewing the proposed architecture, we introduce a learning algorithm called automatic discriminative training which conforms to the practical criteria of a score following system. The novelty of this system lies in the fact that this method, unlike classical methods for HMM training, is not concerned with modeling the music signal but with correctly choosing the sequence of music events that was performed. In this manner, using a discrimination process we attempt to model class boundaries rather than constructing an accurate model for each class. Finally, we demonstrate some results and evaluations of the new system.

2. BACKGROUND

The first debate on learning in the context of score following occurred in Vercoe and Puckette’s historical article [3]. Their learning method, interestingly statistical, allows the synthetic performer to rehearse a work with the live performer and thus produce an effective performance, called “post-performance memory messaging.” This non real-time program begins by calculating the mean of all onset detections, and subsequently tempo matching the mean-corrected deviations to the original score. The standard deviation of the original onset regularities is then computed and used to weaken the importance of each performed event. When subsequent rehearsal takes place, the system uses these weighted values to influence the computation of its least-square fit for metrical prediction. While in Roger Dannenberg’s works before 1997 (or more precisely before the move to a statistical system) there is no report of an explicit training, in Puckette’s article [4], there is evidence of off-line parameter control in three instances: defining the weights used on each constant-Q filter associated with a partial of a pitch in the score, the curve-fitting procedure used to obtain a sharper estimate of fo and threshold used for the input level of the sung voice. According to the article, he did not envision any learning methods to obtain the mentioned parameters. In the first two instances he uses trial and error to obtain global parameters satisfying desired behavior and the threshold is set by hand during performance. Note that in different performances of the same piece, it is this hand-setting of parameters which correlates to the performance style of the musician.

By moving to the probabilistic or statistical score followers, the concept of training becomes more inherent. In Dannenberg and Grubb’s score follower [5], the probability density functions (PDFs) should be obtained in advance and are good candidates for an automatic learning algorithm. In their article, they report three different PDFs in use and they define alternative methods to obtain them, using information based on intuition and experience and information based on empirical investigations of actual performances. A total of 20 recorded performances were used and their pitch detected and labeled time alignment is used to provide an observation distribution for actual pitch given a scored pitch and the required PDFs would be calculated from these hand-discriminated data.

In the HMM score following system of Raphael [6], he trains his statistics (or features in our system’s terminology) using a posterior marginal distribution \( p(x_k | y) \) to re-estimate his feature probabilities in an iterative manner. In his iterative training he uses signatures assigned to each frame for discrimination but no parsing is applied beforehand.

This work was done in the framework of the project SemanticHIFI, funded by the European Commission.
3. APPROACH

Training in the context of score following is to adapt its parameters to a certain style of performance and a certain piece of music. As developed for music performance situations, this system is created to realize the music as opposed to selecting music to demonstrate the technology.

In this respect, we envision a system which adapts itself to correct parameters using a database of sound files of previous performances of the same piece or in the case of a creation, of recorded rehearsals. After the offline and automatic learning, the system is adapted to a certain style of performance, and thus provides better alignment with the score in real-time.

Figure 1 shows a general diagram of Ircam’s current score follower as a refinement of the model described in [7]. In our approach to the described problem, we have refined the observation modeling (upper block) in order to obtain the desired architecture. The decision and alignment block (lower block) is described in detail in [7].

4. OBSERVATION MODELING

Observation in the context of our system consists of calculating features from the audio spectrum in real-time and associate the features as vector valued functions, mapping the high dimensional space into a much lower dimensional space. A more formal one would be to look at the observation process is to consider it as a probability mapping between the feature values and low-level state probabilities. A diagram of the observation process is demonstrated in Figure 2.

In this model, we calculate the low-level feature probabilities associated with each feature which in terms would be multiplied to obtain a certain low-level state probability. As an example, the Log of Energy feature will give three probabilities Log of Energy for Attack, Log of Energy for Sustain and Log of Energy for Rests.

In order to calculate probabilities, each low-level state feature probability (third layer in Figure 2) is using probability mapping functions from a database of stored trained parameters. The probability mapping is derived from Gaussians in forms of cumulative distribution functions (CDFs), inverse cumulative distribution functions or PDFs depending on the heuristics associated with each feature state. This architecture is inspired by Gaussian Mixture Models. Note that the dimension of each model used is one at this time.

By this modeling we have assumed that the low-level states’ attributes are global which is not totally true and would probably fail in extreme cases. However, due to a probabilistic approach, training the parameters over these cases would solve the problem in most cases we have encountered. Another assumption made is the conditional independence among the features, responsible for the final multiplication of the feature as in Figure 2.

5. TRAINING THE SCORE FOLLOWER

In an ideal training, the system runs on a huge database of aligned sound files and adapts its parameters to the performance. In this case, the training is usually supervised and is dependent on system architecture. However, in a musical situation dealing with traditions of music rehearsals and performances, such an ideal procedure would not be possible [2]. In this context, the training will be offline and would use the audio data recorded during rehearsals to train itself.

5.1. The automatic discriminative training

In score following we are not concerned with estimating the joint density of the music data, but are interested in the posterior probability of a musical sequence using the acoustic data. More formally, we are not finally concerned with modeling the music signal, but with correctly choosing the sequence of music events that was performed. Translating this concern to a local level, rather than constructing the set of PDFs that best describe the data, we are interested in ensuring that the correct HMM state is the most probable (according to the model) for each frame.

This leads us to a discriminative training criterion. This criterion has been described in [8] among others. Discriminative training attempts to model the class boundaries — learn the distinction...
between classes — rather than construct as accurate a model as possible for each class. In practice this results in an algorithm that minimizes the likelihood of incorrect, competing models as well as maximizing the likelihood of the correct model.

While most discriminative training methods are supervised, for portability and practical issues, it should be automatic if not unsupervised. For this reason, we introduce an automatic supervision over training by constructing a discrimination knowledge by an alternative algorithm which forces each model to its boundaries and discriminates feature observations. Yin [9] has been chosen as this algorithm to provide discrimination knowledge.

Figure 3 shows a diagram of different steps of this training. The inputs of this training are audio files plus a music score. There are two main cores to this system: Discrimination and Training.

5.2. Discrimination

Using discrimination, we aim to distinguish low-level states in the feature domain. In this process, as part of the training, a set of states and their corresponding observations would be obtained without actually segmenting or labeling the performance. The Yin algorithm [9] is used as the base knowledge. Yin is originally a monophonic fundamental frequency estimator and provides fairly good measures of aperiodicity of each analysis frame. By a one-to-one correspondence between the observed data frames and Yin’s analysis frames, and using Yin’s information for each frame we decide on the type of the associated low-level state (Attack, sustain and release) for each note in the score.

Note that discrimination in this context is implicit and has little to do with the literature on speech discriminative training algorithms. As an analogy, this work is comparable to unsupervised model adaptation algorithms in speech where model parameters are adjusted on the basis of unlabeled training data by making a preliminary recognition. In this way, discrimination knowledge refers to unsupervised labeling of the audio file associated with HMM low-level states.

Figure 4 shows Yin’s \( f_0 \) output together with score information as bands for each different note in the score (an extract of En Echo by Philippe Manoury). These bands are used to find which notes the frame indices belong to. The aperiodicity measure for each frame discriminates release and note events and if the detected note meets a minimum time length, about 20 frames, proximity of the first index would be marked as the attack frame indices as well as the rest for sustain frames. Using these indices, we discriminate attack, release and sustain frames from each feature’s observation. Obviously, each observation frame is assumed to have only one state type.

![Discrimination using Yin](image)

A final remark on Figure 4 is the noisiness of Yin’s measurement which underlies why it is not being used on the first hand in the system itself and the fact that this noisiness will be uncovered during training due to the statistical nature of the algorithm.

5.3. Training

Having all features discriminated, we are ready to train the Gaussians. We evade using fitting algorithms due for robustness issues and use EM Algorithm [10] to construct the Gaussians on observed discriminated features.

The result of the training is a set of PDFs that correspond to each low-level state feature. We go further and construct structures containing \( \mu \) and \( \sigma \) values for each PDF as well as the corresponding type of probability mapping for each state feature. This data will be stored in a database which will be used in the real-time score follower’s observation block as shown in Figure 2.

6. EVALUATION AND RESULTS

An evaluation of a score following system is a wide topic. Recently, we discussed the issue of evaluation in an article published at the NIME conference [1], where objective and subjective evaluation was discussed, suggesting a framework for evaluation of different existing systems.

Evaluating the proposed system along with training results would limit the developers to a subjective evaluation and comparison to previous alignment results and on critical musical phrases. Figure 5 demonstrates this evaluation for two critical music phrases from Philippe Manoury’s piece En Echo for Soprano and live electronics for the previous system used for Ircam’s score follower de-
Fig. 5. Alignment results of the previous system and new system, using the proposed observation block and training results, on measure 39 and measures 29-32 of part I of En Echo. Vertical lines with numbers demonstrate the segmentations associated with the note number in the score.

scribed in [1] and the system proposed in this article after training. Vertical lines show the segmentation results. In overall, the stability of the system has increased and noisiness has been reduced, essential features for real-time following. Alignment is also improved in general and specially for fast phrases.

One important outcome of this learning algorithm is the ability to model and differentiate different styles of performance of a piece specific to different musicians. For a detailed discussion of this feature, we refer the curious reader to our other article in [11]. This algorithm is independent of the system’s architecture.

7. CONCLUSION

In this paper and in the context of a statistical HMM score follower developed at Ircam, we present a new approach for the observation modeling which can articulate specific behavior of the musician in a controllable manner.

Using this approach, a learning algorithm called automatic discriminative training was implemented which conforms to the practical criteria of a score following system. The novelty of this system lies in the fact that this method, unlike classical methods for HMM training, is not concerned with modeling the music signal but with correctly choosing the sequence of music events that was performed. The proposed training is independent of system’s architecture and has led to improvements in real-time alignment. The system tends to model the margins of different styles of performance to a good extent and moreover, might be a point of departure for further studies in the context of learning algorithms for audio signal processing.

8. ACKNOWLEDGMENTS

We are grateful to Philippe Manoury, Serge Lemouton and Andrew Gerzso without whose valuable comments and presence during test sessions the project could not have advanced. We would like to acknowledge Nicola Orio’s ground laying work as the founder of this research project.
