Introduction

By now, the increasing in energy demand, the decrease of fossil resources and the environmental and climate problems caused by these fossil resources are the main challenges of the researchers. To overcome this issues it is necessary to develop optimized and sustainable energy systems. The Compressed Air Energy Storage (CAES) and the development of Net Zero Building (Net ZEB) appear as an appropriate solution for island area with a tropical climate and no connected electric grid as Reunion island. The modelisation of a compressed Air Energy Storage system connected photovoltaic generator (PV), a building and the grid will be the main subject of this study.

Objectives

The main goal of this work is to model the Compressed Air Energy storage system supplied by the photovoltaic field and connected to a building (electric charge) which is also connected the Electric grid as shown the figure below.

The excess electricity produced by the PV is used to power the compressor for storing compressed air in a tank. This air will be used to power an air turbine to power the building's loads when demand rises or will be injected to the electric grid, different scenarios will be studied.

Methodology

The work will follow the diagram below:

State of air:

- GPI: Ideal gas with constant thermal capacity;
- GP: Ideal gas with variable thermal capacity;
- GR: Real gas;
- AH: Humid gas.

Condition of comparison:

<table>
<thead>
<tr>
<th>Component</th>
<th>Temperature (°C)</th>
<th>Pressure (bar)</th>
<th>humidity (%)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Compressor</td>
<td>Inlet</td>
<td>Outlet</td>
<td>Inlet</td>
</tr>
<tr>
<td>Turbine</td>
<td>30</td>
<td>-</td>
<td>1</td>
</tr>
<tr>
<td></td>
<td>50</td>
<td>-</td>
<td>50</td>
</tr>
</tbody>
</table>

Equation used:

\[ w_{\text{comp}} = h_{\text{out,comp}} - h_{\text{in,comp}} \] (1)
\[ w_{\text{comp}} = T_{\text{in,comp}} (s_{\text{out,comp}} - s_{\text{in,comp}}) \] (2)

The equation (1) is used for Isentropic model and equation (2) is used for Isothermal model. The compressor and turbine work is calculated with EES software; using the parameters contained in the table.

Results

The equation (1) is used for Isentropic model and equation (2) is used for Isothermal model.

The compressor and turbine work is calculated with EES software; using the parameters contained in the table.

Conclusion and perspective

For the continuation of this study we envisage a dynamic simulation of the overall system as indicated in the figure below.

Equation for simulation:

\[ \frac{dM_a}{dt} = m_{\text{comp}} - m_{\text{turb}} \] (3)

The equivalent equation is used to calculate the heat storage system, taking into account the eventual loss in the tank and at the heat exchangers. A dynamic coupling of CAES with a building and a renewable energy generation (photovoltaic) will be studied.
