Abstract

In this paper, we derive the crack opening displacement of a penny-shaped crack embedded in an infinite isotropic elastic medium and subjected to a remote constant stress gradient. The solution is derived by taking advantage of the solution of the equivalent ellipsoidal inclusion problem subjected to a linear polarization. The case of the penny-shaped crack is thereafter investigated by considering the case of a spheroidal cavity which has one principal axis infinitesimally small compared to both others. The derivation of the explicit solution for the inhomogeneity subjected to a remote stress gradient raises the problem of the inversion of a sixth order tensor. For the problem having a symmetry axis (this including the case of penny shaped crack), this problem can be tackled by using a decomposition on the canonical basis for transversely isotropic sixth order tensors.

Key words: Cracks, Sixth-order tensor, Anisotropy, Inhomogeneity problem

1 Introduction

This paper provides the explicit solution for the penny shaped crack opening displacement subjected to remote stress gradient. The problem of a crack in an infinite elastic body has been studied for a long time; there is an abundant literature on this subject which has been summarized in the classic books of [16,17,8]. Classically, the problem of crack submitted to an applied remote

strain (or equivalently stress) can be addressed using the Eshelby [3,4] formalism. Eshelby's solution for inclusions and for equivalent inhomogeneity problems are fundamental to many problems in material science, mechanics of composite, etc. In the terminology of Eshelby [3] and Mura [16], an inclusion denotes a subdomain subjected to an eigenstrain while an inhomogeneity is a subdomain whose elastic properties differ from those of the surrounding medium. The main Eshelby's result is well known for the case of a prescribed constant eigenstrain: it shows that a constant strain field is generated inside an ellipsoidal inclusion [3] while the exterior point solution (outside the inclusion) is heterogeneous [4]. The Eshelby's equivalent method handles the problem of a single ellipsoidal inhomogeneity by replacing it with an inclusion having properly chosen eigenstrains. The results for the penny shaped cracks are recovered when two semi-axes of the ellipsoidal inhomogeneity are equal and the last is infinitesimally small compared to the others.

Due to its simplicity, the Eshelby's solution is the basis of numerous ways to understand the behaviour of heterogeneous and cracked materials, and finally was used extensively to construct numerous constitutive equations of these materials. A few recent references show that this field of research is still active for studying cracked materials [11,9]. However, some works have shown also that taking into account the influence of strain (or stress) gradients is of fundamental significance when studying cracked materials, leading to the use of constitutive equations of gradient elasticity type [15,7]. So, extending the Eshelby's formalism to inclusions and cracks submitted to remote strain (or stress) gradients allows to provide a new fundamental background to the understanding of heterogeneous materials. Such a solution was provided in [12] for the case of an ellipsoidal inclusion submitted to a remote gradient, based on older fundamental results. Indeed, following Eshelby's work, Sendeckyj [19], Moschovidis [13], Asaro and Barnett [1], generalize Eshelby's solution to the case of prescribed polynomial fields. In these studies, the following result has been proved: *the strain in an ellipsoidal subdomain of an infinite linear elastic medium which undergoes an eigenstrain on the form of a polynomial of degree N , is also a polynomial with the same degree N .* The expansion of the eigenstrain and the interior point solution for the strain field along polynomial functions introduce tensors of order 2, 3, 4 etc and higher order Eshelby tensors of order 6, 8 etc. It has been pointed out in [16] that the strain disturbance due to a polynomial type remote strain field of degree N can be simulated by an appropriate polynomial eigenstrain field of degree N . If the inclusion problem can be traced back to these works, the related heterogeneity problem requires the inversion of high order tensors. For example, for a remote strain which is linear with coordinates, the problem involves the inversion of a sixth order tensor. Although this inversion can be performed numerically, it is obviously of interest to derive closed form solutions which can cover many applications, as performed in [12].

In the present paper, we use a canonical basis of transversely isotropic sixth order tensors [12] which has the advantage to reduce drastically the size of the

system for the case of a spheroidal inhomogeneity (ellipsoidal inhomogeneity with symmetry axis). It allows to provide an easy inversion of high order tensors and therefore to find an easy way to solve the heterogeneity problem. Thus, the linear system which is initially of dimension 18 reduces to five independent systems of dimension 1, 1, 2, 3 and 4. When the case of a void is considered the problem exhibits some impotent strains and degenerates into five independent systems of dimension 1, 1, 2, 2 and 3. Finally, the case of a penny shaped crack is considered by expanding the solution with respect to the aspect ratio of the spheroidal inhomogeneity.

2 Inhomogeneity problem with applied remote strain or stress gradient

Consider an ellipsoidal inhomogeneity embedded in an infinite elastic matrix and centered at the origin of the cartesian frame (x_1, x_2, x_3) . Let us denote by a_1, a_2, a_3 the semi-axes of the ellipsoid along the three axes of the cartesian frame. The subdomain Ω of the inhomogeneity is defined by:

$$U(x) = \eta_{ij}x_i x_j - 1 \leq 0 \quad (1)$$

with:

$$\eta_{ij} = \begin{cases} 0 & \text{if } i \neq j \\ 1/a_i^2 & \text{if } i = j \end{cases} \quad (2)$$

Both the inhomogeneity and the infinite domain are assumed to be isotropic and we denote by μ, λ and μ_0, λ_0 their respective Lamé coefficients. The inhomogeneity is subjected to a remote strain field taken on the form $\varepsilon_{ij}(x) = \varepsilon_{ijk}^\infty x_k$ or equivalently to the remote stress field $\sigma_{ij}(x) = \sigma_{ijk}^\infty x_k$ where ε_{ijk}^∞ and σ_{ijk}^∞ are constant ($\underline{x}$ -independent). This problem is called "second order heterogeneity problem" since a uniform gradient of strain (or stress) is applied instead of the constant strain considered by Eshelby in the first order problem. The strain and stress are related outside the heterogeneity by:

$$\sigma_{ijk}^\infty = C_{ijpq}^0 \varepsilon_{pqk}^\infty \quad (3)$$

At infinity, the equilibrium for the applied remote stress is:

$$\sigma_{ijj}^\infty = C_{ijpq}^0 \varepsilon_{pqj}^\infty = 0 \quad (4)$$

ε_{ijk}^∞ and σ_{ijk}^∞ being symmetric with respect to indices i and j and accounting for the equilibrium condition (4), we deduce that they both depend on 15 independent coefficients.

The strain disturbance due to the application of ε_{ijk}^∞ at infinity can be obtained by considering the following appropriate inclusion problem: an ellipsoidal domain, defined by (1), is subjected to a prescribed eigenstrain of the form $\varepsilon_{ij}^*(x) = e_{ijk}x_k$ (with $e_{ijk} = e_{jik}$). As shown in [19], [13] and also in [1] for the more general case of an anisotropic matrix, the solution is defined by a linear strain within the inclusion:

$$\varepsilon_{ij}(x) = S_{ijkpqr}e_{pqr}x_k \quad (5)$$

where S_{ijkpqr} are the components of a sixth-order Eshelby tensor (to make reference to the common fourth order Eshelby tensor when dealing with constant eigenstrain within the inclusion domain). The expression of the stress components (still within the inclusion) are:

$$\sigma_{ij}(x) = C_{ijmn}^0(S_{mnkpqr}e_{pqr} - e_{mnk})x_k \quad (6)$$

The components of the sixth order Eshelby tensor are:

$$\begin{aligned} 8\pi(1 - \nu_0)S_{ijkpqr} = & \{ \delta_{ij}\delta_{kr}\delta_{pq} [T_{IPR} + 2\nu_0 I_{IR}] \\ & + 2I_{ijpq}\delta_{kr} [T_{IJR} + (1 - \nu_0)(I_{IR} + I_{JR})] \\ & + 2I_{pqkr}\delta_{ij}T_{IKR} + 2I_{ijkp}\delta_{qr} [T_{IJP} + 2\nu_0 I_{IJ}] \\ & + 2(I_{ijpr}\delta_{kq} + I_{ijqr}\delta_{kp}) [T_{PQR} + (1 - \nu_0)I_{KR}] \\ & + 2(I_{ijkp}\delta_{qr} + I_{ijkq}\delta_{pr}) [T_{KPQ} + (1 - \nu_0)I_{KR}] \} a_R^2 \end{aligned} \quad (7)$$

In which some specific notations introduced in [16] have been also used: repeated lower case indices are summed from 1 to 3; upper case indices take on the same values as the corresponding lower case ones but are not summed. For example, in the monomial $a_i a_i b_I$, the repeated indice is i and the upper case indice takes the same value as i ; it gives: $a_i a_i b_I = a_1^2 b_1 + a_2^2 b_2 + a_3^2 b_3$. An other example is $a_i b_I$, here i is not summed and this monomial are the components of a thirist order tensor whose components are: $a_1 b_1, a_2 b_2, a_3 b_3$. In (7), I_{ij} and T_{ijk} are invariant by any permutation of their indices and they are defined in terms of elliptic integrals:

$$\begin{aligned} I_{ij} &= 2\pi a_1 a_2 a_3 \int_0^{+\infty} \frac{ds}{(a_i^2 + s)(a_j^2 + s)\Delta(s)} \\ T_{ijk} &= 2\pi a_1 a_2 a_3 \int_0^{+\infty} \frac{s ds}{(a_i^2 + s)(a_j^2 + s)(a_k^2 + s)\Delta(s)} \end{aligned} \quad (8)$$

with: $\Delta(s) = (a_1^2 + s)^{1/2}(a_2^2 + s)^{1/2}(a_3^2 + s)^{1/2}$. There are explicit expressions for these integrals when at least two semi-axes are equal (that corresponding to an oblate or a prolate spheroidal inclusion). These expressions are provided in appendix.

Let us now come back to the inhomogeneity problem. Using the equivalent Eshelby inclusion method, the eigenstrain $\varepsilon_{ij}^*(x)$ is chosen as:

$$\varepsilon_{ij}^*(x) = Y_{ijpq}\varepsilon_{pq}(x) \quad (9)$$

where Y_{ijpq} is defined by:

$$Y_{ijpq} = \alpha\delta_{ij}\delta_{pq}/3 + \beta(I_{ijpq} - \delta_{ij}\delta_{pq}/3) \quad (10)$$

with:

$$\alpha = 1 - \frac{k}{k_0}, \quad \beta = 1 - \frac{\mu}{\mu_0} \quad (11)$$

where $k = \lambda + 2\mu/3$ and $k_0 = \lambda_0 + 2\mu_0/3$ are the compressibility moduli of the inhomogeneity and of the infinite medium. The strain field in the ellipsoidal inhomogeneity is also linear according to the vector position and can then be written as $\varepsilon_{ij}(x) = a_{ijk}x_k$ where a_{ijk} are the components of a constant third-order tensor $\mathbf{a}$ which possesses the symmetry with respect to its two first indices. The strain field, solution of the inhomogeneity problem, is the sum of: (i) the prescribed remote strain field $\varepsilon_{ij}(x) = \varepsilon_{ijk}^\infty x_k$, (ii), the disturbed strain field due to the applied eigenstrain $\varepsilon_{ij}^*(x) = e_{ijk}x_k$ where e_{ijk} is related to a_{ijk} by $e_{ijk} = Y_{ijpq}a_{pqk}$. It follows that $\mathbf{a}$ is solution of the linear system:

$$[I_{ijkpqr} - S_{ijkmnr}Y_{mnpq}]a_{pqr} = \varepsilon_{ijk}^\infty \quad (12)$$

in which I_{ijkpqr} are the components of the sixth-order identity tensor given by:

$$I_{ijkpqr} = \frac{1}{2}(\delta_{ip}\delta_{jq} + \delta_{iq}\delta_{jp})\delta_{kr} \quad (13)$$

The resolution of equation (12) involves the inversion of a sixth order tensor, that constitutes the main difficulty when dealing with arbitrary ellipsoidal inhomogeneities. This equation can be also written by using the applied gradient of stress $\boldsymbol{\sigma}^\infty$ as second member in the linear system:

$$C_{ijuv}^0 [I_{uvkpqr} - S_{uvkmnr}Y_{mnpq}]a_{pqr} = \sigma_{ijk}^\infty \quad (14)$$

and can be recast into the following tensorial form:

$$\mathbb{A} \odot_3 \mathbf{a} = \boldsymbol{\sigma}^\infty \quad (15)$$

where $\mathbb{A}$ is the sixth order tensor whose components are:

$$A_{ijkpqr} = C_{ijuv}^0 [I_{uvkpqr} - S_{uvkmnr} Y_{mnpq}] \quad (16)$$

and $\odot_3$ denotes the inner product on three indices defined by $(\mathbb{A} \odot_3 \mathbf{a})_{ijk} = A_{ijkpqr} a_{pqr}$. Tensor $\mathbb{A}$ can be written with the following equivalent form:

$$\mathbb{A} = \mathbb{C}^0 \odot_3 (\mathbb{I} - \mathbb{S} \odot_3 \mathbb{Y}) \quad (17)$$

in which $\mathbb{I}$ is the sixth order identity tensor and $\mathbb{S}$ is the sixth order Eshelby tensor whose components are given by (13) and (7) respectively. In (17), $\mathbb{C}^0$ and $\mathbb{Y}$ are also two sixth order tensors; their components are $C_{ijkpqr}^0 = C_{ijpq}^0 \delta_{kr}$ and $Y_{ijkpqr} = Y_{ijpq} \delta_{kr}$ in which Y_{ijpq} are given by (10). Obviously, C_{ijpq}^0 and Y_{ijpq} are associated with fourth order tensors; however the introduction of sixth order tensors is more suitable since the computation of the components of $\mathbb{A}$ can be made in term of those of $\mathbb{C}^0$, $\mathbb{I}$, $\mathbb{S}$ and $\mathbb{Y}$ by using an irreducible representation with a canonical basis (this is detailed in the next section). Since any third order tensor with previously defined symmetries depends on 18 independent coefficients, the direct inversion of tensor $\mathbb{A}$ involves one of a matrix of dimensions 18×18 . Since the problem has symmetries, it is possible to represent sixth order tensors by using an irreducible basis, which reduces significantly the size of the system.

When dealing with the case of voids, particular attention must be paid since tensor $\mathbb{A}$ is singular and the linear system (15) has no more a unique solution for $\mathbf{a}$. This has been already pointed out by [6] (see also [16,18,22]). Indeed, in the case of a cavity we put $k = \mu = 0$ in (10), it follows that $\mathbb{Y} = \mathbb{I}$ and tensor $\mathbb{A}$ becomes:

$$\mathbb{A} = \mathbb{C}^0 \odot_3 (\mathbb{I} - \mathbb{S}) \quad (18)$$

Let $\mathcal{A}(\mathbf{a})$ being the linear application defined by $\mathcal{A}(\mathbf{a}) : \mathbf{a} \rightarrow \mathbb{A} \odot_3 \mathbf{a}$, the kernel of the linear application $\mathcal{A}(\mathbf{a})$ is the space of dimension 3:

$$\text{Ker}(\mathcal{A}) = \{\mathbf{a} | a_{ijk} = \theta_i \eta_{jk} + \theta_j \eta_{ik}\} \quad (19)$$

where θ_i are the components of an arbitrary vector and η_{ij} is related to the ellipsoid shape by (2). The kernel of $\mathcal{A}$ is associated with some impotent eigenstrains [6] which do not produce a stress field around the inhomogeneity. In the case of voids, the strain $\varepsilon_{ij}(x) = a_{ijk}x_k$ is obtained by making a continuation by continuity of the displacement field within the cavity; however, this continuation is not unique, since there exist some displacement fields which produce constant gradients of strain within the void and which are null on its boundary. These displacements read:

$$u_i(x) = \theta_i(\eta_{pq}x_px_q - 1) \quad (20)$$

where the term $\eta_{pq}x_px_q$ takes the value 1 for a point located on the boundary of the ellipsoidal void. The displacement (20) produces the strain $\varepsilon_{ij}(x) = \theta_i\eta_{jk}x_k + \theta_j\eta_{ik}x_k$ and then the constant gradient of strain $\theta_i\eta_{jk} + \theta_j\eta_{ik}$. On another hand, by examining the equilibrium condition for the stress field solution of the inclusion problem, that corresponding to $j = k$ in relation (6), we observe that:

$$A_{ijjppqr} = 0 \quad (21)$$

It follows that the image of the application $\mathcal{A}$ is defined by :

$$\text{Im}(\mathcal{A}(\mathbf{a})) = \{\mathbf{b} \mid b_{ijj} = 0\} \quad (22)$$

and is of dimension 15. We conclude that in the case of voids, the linear system degenerates into a problem of dimension 15.

3 Case of spheroidal inhomogeneities: decomposition on a canonical basis for transversely isotropic sixth order tensor

The case of spheroidal inhomogeneities corresponds to $a_1 = a_2$. In this case, the sixth order Eshelby tensor, and then also tensor $\mathbb{A}$, is invariant by any rotation around the axis Ox_3 and by the reflection related to the plane Ox_1x_2 . This corresponds to the transversely isotropic symmetry, for which decomposition of a sixth order tensor on a canonical basis is possible [12].

Any transversely isotropic sixth order $\mathbb{A}$ can be decomposed as follows:

$$\mathbb{A} = \sum_{n=1}^{n=31} a_n \mathbb{T}_n \quad (23)$$

where the a_n are the components of the tensor $\mathbb{A}$ in the basis $(\mathbb{T}_1, \dots, \mathbb{T}_{31})$. The definitions for tensors $\mathbb{T}_n$ can be found in [12]. The set of tensors $(\mathbb{T}_1, \dots, \mathbb{T}_{31})$ is constituted of 5 groups which are independent for the composition $\odot_3$. These groups are $\{\mathbb{T}_1\}$, $\{\mathbb{T}_2\}$, $\{\mathbb{T}_3, \dots, \mathbb{T}_6\}$, $\{\mathbb{T}_7, \dots, \mathbb{T}_{15}\}$, $\{\mathbb{T}_{16}, \dots, \mathbb{T}_{31}\}$, and define subspaces whose dimensions are respectively: 1, 1, 4, 9, 25. It follows that an alternative representation for $\mathbb{A}$ is:

$$\mathbb{A} = \{a_1, a_2, A_1, A_2, A_3\} \quad (24)$$

in which A_1 , A_2 et A_3 are matrices defined by :

$$A_1 = \begin{bmatrix} a_3 & a_4 \\ a_5 & a_6 \end{bmatrix}, \quad A_2 = \begin{bmatrix} a_7 & a_8 & a_9 \\ a_{10} & a_{11} & a_{12} \\ a_{13} & a_{14} & a_{15} \end{bmatrix}, \quad A_3 = \begin{bmatrix} a_{16} & a_{17} & a_{18} & a_{19} \\ a_{20} & a_{21} & a_{22} & a_{23} \\ a_{24} & a_{25} & a_{26} & a_{27} \\ a_{28} & a_{29} & a_{30} & a_{31} \end{bmatrix} \quad (25)$$

and is called compact representation of $\mathbb{A}$ since this form is irreducible for such a symmetry.

These notations are very useful for performing the usual tensorial operations. For instance the product between two sixth order tensors $\mathbb{A}$ and $\mathbb{B}$ are obtained by making the product of the elements of their respective compact representation:

$$\mathbb{A} \odot_3 \mathbb{B} = \{a_1 b_1, a_2 b_2, A_1 B_1, A_2 B_2, A_3 B_3\} \quad (26)$$

and the inverse of $\mathbb{A}$ is:

$$\mathbb{A}^{-1} = \left\{ \frac{1}{a_1}, \frac{1}{a_2}, A_1^{-1}, A_2^{-1}, A_3^{-1} \right\} \quad (27)$$

with the following invertibility condition $a_1 a_2 \det(A_1) \det(A_2) \det(A_3) \neq 0$. Coming back now to the inhomogeneity problem, the inversion of $\mathbb{A}$ is effected with relation (27), where the expressions of the elements of its compact representation are obtained by the sum and product of tensors $\mathbb{I}$, $\mathbb{S}$ and $\mathbb{Y}$. The elements of the compact representation of tensor $\mathbb{A}$ given by (17), are:

$$\begin{aligned} a_1 &= 2\mu_0(1 - \beta s_1), \quad a_2 = 2\mu_0(1 - \beta s_2), \quad A_1 = C_1^0(I_2 - S_2 Y_2), \\ A_2 &= C_2^0(I_3 - S_3 Y_3), \quad A_3 = C_3^0(I_4 - S_3 Y_3) \end{aligned} \quad (28)$$

in which I_2 , I_3 and I_4 are the identity matrices of dimension 2, 3 and 4 respectively. Matrices S_2 , S_3 , S_4 and Y_2 , Y_3 , Y_4 and also C_1^0 , C_2^0 , C_3^0 can be found in

appendix.

The relationship $\boldsymbol{\sigma}^\infty = \mathbb{A} \odot_3 \mathbf{a}$ can be put into the form:

$$\begin{aligned} \sigma_1^\infty &= a_1 \mathbf{a}_I, \quad \sigma_2^\infty = a_2 \mathbf{a}_{II}, \quad \begin{bmatrix} \sigma_{III}^\infty \\ \sigma_{IV}^\infty \end{bmatrix} = A_1 \begin{bmatrix} \mathbf{a}_{III} \\ \mathbf{a}_{IV} \end{bmatrix}, \\ \begin{bmatrix} \sigma_V^\infty \\ \sigma_{VI}^\infty \\ \sigma_{VII}^\infty \end{bmatrix} &= A_2 \begin{bmatrix} a_V \\ a_{VI} \\ a_{VII} \end{bmatrix}, \quad \begin{bmatrix} \sigma_{VIII}^\infty \\ \sigma_{IX}^\infty \\ \sigma_X^\infty \\ \sigma_{XI}^\infty \end{bmatrix} = A_3 \begin{bmatrix} \mathbf{a}_{VIII} \\ \mathbf{a}_{IX} \\ \mathbf{a}_X \\ \mathbf{a}_{XI} \end{bmatrix} \end{aligned} \quad (29)$$

where the following notations have been used:

$$\begin{aligned} \mathbf{a}_I &= \begin{bmatrix} (a_{112} + 2a_{121} - a_{222})/4 \\ (a_{221} + 2a_{122} - a_{111})/4 \end{bmatrix}, \quad a_{II} = a_{132} - a_{231}, \\ \mathbf{a}_{III} &= \begin{bmatrix} (a_{113} - a_{223})/2 \\ a_{123} \end{bmatrix}, \quad \mathbf{a}_{IV} = \begin{bmatrix} a_{131} - a_{232} \\ a_{132} + a_{231} \end{bmatrix}, \\ a_V &= (a_{113} + a_{223})/2, \quad a_{VI} = a_{131} + a_{232}, \quad a_{VII} = a_{333}, \\ \mathbf{a}_{VIII} &= \begin{bmatrix} (a_{111} - a_{221})/2 + a_{122} \\ (a_{222} - a_{112})/2 + a_{121} \end{bmatrix}, \quad \mathbf{a}_{IX} = \begin{bmatrix} (a_{111} + 3a_{221})/4 - a_{122}/2 \\ (a_{222} + 3a_{112})/4 - a_{121}/2 \end{bmatrix}, \\ \mathbf{a}_X &= \begin{bmatrix} a_{331} \\ a_{332} \end{bmatrix}, \quad \mathbf{a}_{XI} = \begin{bmatrix} a_{133} \\ a_{233} \end{bmatrix} \end{aligned} \quad (30)$$

and the same notations are considered for the applied stress gradient $\boldsymbol{\sigma}^\infty$. It provides a direct link between the components of $\boldsymbol{\sigma}^\infty$ and those of tensor $\mathbf{a}$ when they are written in the cartesian frame aligned with the axis of transverse isotropy (axis Ox_3).

The computation of the components of the strain for an interior point as a function of the applied remote stress gradient then involves the inversion of two scalars and matrices of dimension 2, 3 and 4. With this compact representation, the size of the problem is significantly reduced. When the case of voids is considered, the problem can be again reduced since, as mentioned in the previous section, the problem initially of dimension 18 degenerates to a problem of dimension 15.

Let us examine the case of void more precisely. The elements of the compact representation of $\mathbb{A}$ are obtained by putting $\beta = 1$ and Y_1, Y_2 and Y_3 are the identity matrices. This leads to:

$$\begin{aligned} a_1 &= 2\mu_0(1 - s_1), \quad a_2 = 2\mu_0(1 - s_2), \quad A_1 = C_1^0(I_2 - S_2), \\ A_2 &= C_2^0(I_3 - S_3), \quad A_3 = C_3^0(I_4 - S_3) \end{aligned} \quad (31)$$

a_1, a_2 and all the components of A_1, A_2, A_3 are given in appendix. The components of matrices A_2 and A_3 which are formally given by (25) comply with the following relations:

$$\begin{aligned} \left\{ \begin{array}{l} a_9\epsilon^2 + a_8 = 0 \\ a_{12}\epsilon^2 + a_{11} = 0 \\ a_{15}\epsilon^2 + a_{14} = 0 \end{array} \right. \text{group (a)} & \quad \left\{ \begin{array}{l} a_{10} + a_{13} = 0 \\ a_{11} + a_{14} = 0 \\ a_{12} + a_{15} = 0 \end{array} \right. \text{group (b)} \\ \left\{ \begin{array}{l} 2a_{16}\epsilon^2 + a_{19} = 0 \\ 2a_{20}\epsilon^2 + a_{23} = 0 \\ 2a_{24}\epsilon^2 + a_{27} = 0 \\ 2a_{24}\epsilon^2 + a_{31} = 0 \end{array} \right. \text{group (c)} & \quad \left\{ \begin{array}{l} 3a_{16} + 2a_{20} + 2a_{24} = 0 \\ 3a_{17} + 2a_{21} + 2a_{25} = 0 \\ 3a_{18} + 2a_{22} + 2a_{26} = 0 \\ 3a_{19} + 2a_{23} + 2a_{27} = 0 \end{array} \right. \text{group (d)} \end{aligned} \quad (32)$$

in which we have introduced the aspect ratio:

$$\epsilon = \frac{a}{b} \quad (33)$$

The group of equations (a) and (c) shows that the solution for $\mathbf{a}$ is not unique, because the second and the third columns of matrix A_2 are proportional, as are the first and last columns of A_3 .

In fact, this set of equations contains some impotent strains which read for the spheroidal inhomogeneity:

$$\begin{aligned} \mathbf{a}_I &= 0, \quad a_{II} = 0, \quad \mathbf{a}_{III} = 0, \quad \mathbf{a}_{IV} = 0, \quad a_V = 0, \quad a_{VI} = \frac{2}{b^2}\theta_3, \\ a_{VII} &= \frac{2}{a^2}\theta_3, \quad \mathbf{a}_{VIII} = \frac{2}{b^2} \begin{bmatrix} \theta_1 \\ \theta_2 \end{bmatrix}, \quad \mathbf{a}_{IX} = 0, \quad \mathbf{a}_X = 0, \quad \mathbf{a}_{XI} = \frac{1}{a^2} \begin{bmatrix} \theta_1 \\ \theta_2 \end{bmatrix} \end{aligned} \quad (34)$$

From another point of view, the group of equations (b) and (d) is the detailed expression of the equilibrium condition (21).

By eliminating the equilibrium and the impotent components of $\mathbf{a}$ we obtain the following reduced linear system for the spheroidal cavities:

$$\begin{aligned}
\sigma_I^\infty &= a_1 \mathbf{a}_I, \quad \sigma_{II}^\infty = a_2 a_{II}, \quad \begin{bmatrix} \sigma_{III}^\infty \\ \sigma_{IV}^\infty \end{bmatrix} = A_1 \begin{bmatrix} \mathbf{a}_{III} \\ \mathbf{a}_{IV} \end{bmatrix}, \\
\begin{bmatrix} \sigma_V^\infty \\ \sigma_{VI}^\infty \end{bmatrix} &= \overline{A}_2 \begin{bmatrix} a_V \\ a_{VI} - \epsilon^2 a_{VII} \end{bmatrix}, \quad \begin{bmatrix} \sigma_{VIII}^\infty \\ \sigma_{IX}^\infty \\ \sigma_X^\infty \end{bmatrix} = \overline{A}_3 \begin{bmatrix} \mathbf{a}_{VIII} - \epsilon^2 \mathbf{a}_{XI} \\ \mathbf{a}_{IX} \\ \mathbf{a}_X \end{bmatrix}
\end{aligned} \tag{35}$$

which corresponds to 15 scalar coefficients.

In addition, the reduced matrices $\overline{A}_2$ and $\overline{A}_3$ are defined by:

$$\overline{A}_2 = \begin{bmatrix} a_7 & a_8 \\ a_{10} & a_{11} \end{bmatrix}, \quad \overline{A}_3 = \begin{bmatrix} a_{16} & a_{17} & a_{18} \\ a_{20} & a_{21} & a_{22} \\ a_{24} & a_{25} & a_{26} \end{bmatrix} \tag{36}$$

In the case of void, the resolution of the linear system consists then in the inversion of two scalars (a_1 and a_2), two matrices of dimension 2 (A_1 and $\overline{A}_2$) and one matrix of dimension 3 ($\overline{A}_3$). Explicit solutions are now provided in the case of the penny shaped crack.

4 Solution for the penny-shaped crack

The case of a penny-shaped crack is the special case of an oblate spheroidal void when its radius a along the Ox_3 axis vanishes. Taking the limit $\epsilon \rightarrow 0$ in a_1 , a_2 and in matrices A_1 , $\overline{A}_2$, $\overline{A}_3$, we obtain the following expressions at the first order:

$$\begin{aligned}
a_1 &= 2\mu_0 - \frac{3\pi}{16} \frac{7 - 8\nu_0}{1 - \nu_0} \epsilon + o(\epsilon), \\
a_2 &= \frac{3\mu_0\pi}{2} \epsilon + o(\epsilon), \\
A_1 &= A_1^{(0)} + \epsilon A_1^{(1)} + o(\epsilon), \\
\overline{A}_2 &= \overline{A}_2^{(0)} + \epsilon \overline{A}_2^{(1)} + o(\epsilon), \\
\overline{A}_3 &= \overline{A}_3^{(0)} + \epsilon \overline{A}_3^{(1)} + o(\epsilon)
\end{aligned} \tag{37}$$

with:

$$\begin{aligned}
A_1^{(0)} &= 2\mu_0 \begin{bmatrix} 1 & -1 \\ 0 & 0 \end{bmatrix}, \quad A_1^{(1)} = \frac{3\mu_0\pi}{8(1-\nu_0)} \begin{bmatrix} 0 & 5-4\nu_0 \\ 0 & 2(2-\nu_0) \end{bmatrix}, \\
\overline{A}_2^{(0)} &= \frac{2\mu_0(1+\nu_0)}{1-\nu_0} \begin{bmatrix} 1 & -1 \\ 0 & 0 \end{bmatrix}, \quad \overline{A}_2^{(1)} = \frac{3\mu_0\pi}{4(1-\nu_0)} \begin{bmatrix} 0 & 3+2\nu_0 \\ 0 & 2 \end{bmatrix} \\
\overline{A}_3^{(0)} &= \frac{2\mu_0}{1-\nu_0} \begin{bmatrix} 1-\nu_0 & 0 & 0 \\ \nu_0 & 1+\nu_0 & 0 \\ 0 & 0 & 0 \end{bmatrix}, \\
\overline{A}_3^{(1)} &= \frac{3\mu_0\pi}{16(1-\nu_0)} \begin{bmatrix} -2(5-4\nu_0) & -6 & 2(1-2\nu_0) \\ -(1+\nu_0) & -(3+8\nu_0) & (1+6\nu_0) \\ 4 & 4(1+2\nu_0) & 4 \end{bmatrix}
\end{aligned} \tag{38}$$

The limit $\epsilon \rightarrow 0$ corresponds to two very close circular surface across which a jump of the displacement field is generated. This jump can be deduced from the interior point solution for the strain. Indeed, when the limit $\epsilon \rightarrow 0$ is taken, the strain can be expanded as a power series in ϵ :

$$\mathbf{a} = \frac{1}{\epsilon} \mathbf{a}^{(-1)} + \mathbf{a}^{(0)} + \epsilon \mathbf{a}^{(1)} + \dots \tag{39}$$

where the dominant term $\mathbf{a}^{(-1)}$ is associated with the singularity. Accounting for the decomposition (24) and collecting all the terms with the same power in ϵ in the linear system (35), we obtain a hierarchy of problems for all the components of $\mathbf{a}$ at every order. The resolution of each linear system leads to the following expressions for the dominant terms:

$$\begin{aligned}
\mathbf{a}_I^{(-1)} &= 0, \quad \mathbf{a}_{II}^{(-1)} = \frac{2}{3\mu_0\pi} \sigma_{II}^\infty, \quad \mathbf{a}_{III}^{(-1)} = \mathbf{a}_{IV}^{(-1)} = \frac{4(1-\nu_0)}{3\mu_0\pi(2-\nu_0)} \boldsymbol{\sigma}_{IV}^\infty, \\
\mathbf{a}_V^{(-1)} &= \mathbf{a}_{VI}^{(-1)} = \frac{2(1-\nu_0)}{3\mu_0\pi} \sigma_{VI}^\infty, \quad \mathbf{a}_{VIII}^{(-1)} = \mathbf{a}_{IX}^{(-1)} = 0, \quad \mathbf{a}_X^{(-1)} = \frac{4(1-\nu_0)}{3\mu_0\pi} \boldsymbol{\sigma}_X^\infty
\end{aligned} \tag{40}$$

The terms $\mathbf{a}_{VII}^{(-1)}$ and $\mathbf{a}_{XI}^{(-1)}$, which are associated to impotent strains, remain undetermined. From (40) with definitions (30), we obtain the following expressions for the components of $\mathbf{a}$ in the cartesian frame:

$$\begin{aligned}
a_{111}^{(-1)} &= a_{112}^{(-1)} = a_{121}^{(-1)} = a_{122}^{(-1)} = a_{221}^{(-1)} = a_{222}^{(-1)} = 0 \\
a_{131}^{(-1)} &= \frac{1 - \nu_0}{3\pi\mu_0(2 - \nu_0)} [(4 - \nu_0)\sigma_{131}^\infty - \nu_0\sigma_{232}^\infty] \\
a_{132}^{(-1)} &= \frac{1}{3\pi\mu_0(2 - \nu_0)} [(4 - 3\nu_0)\sigma_{132}^\infty - \nu_0\sigma_{231}^\infty] \\
a_{231}^{(-1)} &= \frac{1}{3\pi\mu_0(2 - \nu_0)} [(4 - 3\nu_0)\sigma_{231}^\infty - \nu_0\sigma_{132}^\infty] \\
a_{232}^{(-1)} &= \frac{1 - \nu_0}{3\pi\mu_0(2 - \nu_0)} [(4 - \nu_0)\sigma_{232}^\infty - \nu_0\sigma_{131}^\infty] \\
a_{331}^{(-1)} &= \frac{4(1 - \nu_0)}{3\mu_0\pi}\sigma_{331}^\infty, \quad a_{332}^{(-1)} = \frac{4(1 - \nu_0)}{3\mu_0\pi}\sigma_{332}^\infty \\
a_{113}^{(-1)} &= 2a_{131}^{(-1)}, \quad a_{223}^{(-1)} = 2a_{232}^{(-1)}, \quad a_{123}^{(-1)} = a_{132}^{(-1)} + a_{231}^{(-1)}
\end{aligned} \tag{41}$$

The strain field being determined for the interior points, one can deduce the solution for the displacement at the surface of the crack. The strain field being linear with respect to the coordinates, the components of the displacement field for the interior points are:

$$u_i = U_i + \frac{1}{2}K_{ijk}x_jx_k \tag{42}$$

The components K_{ijk} can be easily computed from:

$$a_{ijk} = \frac{1}{2}(u_{i,jk} + u_{j,ik}) = \frac{1}{2}(K_{ijk} + K_{jik}) \tag{43}$$

which, by inversion, leads to:

$$K_{ijk} = a_{ijk} + a_{ikj} - a_{jki} \tag{44}$$

It is not necessary to compute the constants U_i for $i = 1..3$ since they do not enter in the expression of the displacement jump vector. Let us now introduce the cylindrical coordinates (r, θ, z) centered at the origin and such that $z \equiv x_3$. The radial coordinate r denotes the distance between the crack center and a current position. For a given value of r and θ we can define the two opposite positions z_+ and z_- on the surface of the spheroid (see figure 1). Those positions are:

$$z_+ = \epsilon\sqrt{b^2 - r^2}, \quad z_- = -\epsilon\sqrt{b^2 - r^2} \tag{45}$$

The jump of displacement across the crack can be obtained by comparing the value of the displacements for two opposite points taken on the surface of the spheroid, then by taking the limit $\epsilon \rightarrow 0$:

$$[\underline{u}] = \lim_{\epsilon \rightarrow 0} \left[\underline{u}(r, \theta, \epsilon\sqrt{b^2 - r^2}) - \underline{u}(r, \theta, -\epsilon\sqrt{b^2 - r^2}) \right] \quad (46)$$

Fig. 1. Radial coordinate and heights z_+ and z_- for two opposite points taken on the surface of a spheroid

Denoting the displacement jump by:

$$\Delta \underline{u} = \underline{u}(r, \theta, \epsilon\sqrt{b^2 - r^2}) - \underline{u}(r, \theta, -\epsilon\sqrt{b^2 - r^2}) \quad (47)$$

It can be found, from (42) together with (44), that:

$$\begin{aligned} \Delta u_1 &= 2r\epsilon\sqrt{b^2 - r^2} \left[a_{113} \cos(\theta) + (a_{132} + a_{123} - a_{231}) \sin(\theta) \right] \\ \Delta u_2 &= 2r\epsilon\sqrt{b^2 - r^2} \left[(a_{123} + a_{231} - a_{132}) \cos(\theta) + a_{223} \sin(\theta) \right] \\ \Delta u_3 &= 2r\epsilon\sqrt{b^2 - r^2} \left[(a_{331} \cos(\theta) + a_{332} \sin(\theta)) \right] \end{aligned} \quad (48)$$

Finally, replacing the components of a_{ijk} by (39) together with (41) and taking the limit $\epsilon \rightarrow 0$, we obtain:

$$\begin{aligned}
[u_1] &= \frac{4}{3\pi\mu_0(2-\nu_0)}r\sqrt{b^2-r^2}\left[(1-\nu_0)((4-\nu_0)\sigma_{131}^\infty - \nu_0\sigma_{232}^\infty)\cos(\theta) \right. \\
&\quad \left. + ((4-3\nu_0)\sigma_{132}^\infty - \nu_0\sigma_{231}^\infty)\sin(\theta)\right] \\
[u_2] &= \frac{4}{3\pi\mu_0(2-\nu_0)}r\sqrt{b^2-r^2}\left[(4-3\nu_0)\sigma_{231}^\infty - \nu_0\sigma_{132}^\infty)\cos(\theta) \right. \\
&\quad \left. + (1-\nu_0)((4-\nu_0)\sigma_{232}^\infty - \nu_0\sigma_{131}^\infty)\sin(\theta)\right] \\
[u_3] &= \frac{8(1-\nu_0)}{3\pi\mu_0}r\sqrt{b^2-r^2}\left[\sigma_{331}^\infty\cos(\theta) + \sigma_{332}^\infty\sin(\theta)\right]
\end{aligned} \tag{49}$$

Note that the solution at the first order shows that the displacement jump vector depends only on the stress components acting on the plane of the crack i.e. σ_{13}^∞ , σ_{23}^∞ and σ_{33}^∞ . When a stress gradient is applied at infinity, the solution for the sliding mode gives a dependence of $[u_1]$ and $[u_2]$ with the derivatives of the shear stress components along the x_1 and x_2 directions. Considering the opening mode, $[u_3]$, it depends on the derivatives of the normal stress along the x_1 and x_2 directions.

5 Conclusion

In this paper we have derived the displacement jump vector occurring across a penny-shaped crack embedded in an infinite elastic matrix and subjected to a remote gradient of strain, extending older results corresponding to displacement jumps induced by a constant strain at infinity. The method takes advantage of the problem of the inclusion subjected to a polarization that is linear with the coordinates. The problem is thus reduced to the inversion of a sixth order tensor. This inversion is formally equivalent to the resolution of a system of dimension 18. For the case of a spheroidal inhomogeneity, the problem has been proved to be greatly reduced by using a canonical basis for transversely isotropic sixth order tensors. More particularly, attention has been focused on cavities for which the problem becomes singular which is attributed to the presence of impotent strains which remain undetermined. Eliminating the impotent strains leads to a reduced linear system which has been also formulated for the case of cavities.

Finally, the particular case of penny-shaped cracks is studied and the closed form solution for the crack opening displacement has been provided. This extends the classical solution for the jump induced across a penny-shaped crack when a constant strain field is applied at infinity.

A Elements of the compact representation of tensors $\mathbb{S}$, $\mathbb{Y}$, $\mathbb{C}^0$ and $\mathbb{A}$

The elliptic integrals, given by relation (8), are given by:

$$\begin{aligned}
I_{11} &= I_{22} = I_{12} = \frac{\pi(3(\eta - 1) + 2\epsilon^2)}{2b^2(\epsilon^2 - 1)}, \quad I_{13} = I_{23} = \frac{2\pi(1 - 3\eta)}{b^2(\epsilon^2 - 1)} \\
I_{33} &= \frac{4\pi(3\eta\epsilon^2 - 1)}{3b^2\epsilon^2(\epsilon^2 - 1)} \\
T_{111} &= T_{112} = T_{122} = T_{222} = \frac{\pi(6\epsilon^2(2 - 3\eta) + 3(\eta - 1) - 4a^4)}{12b^2(\epsilon^2 - 1)^2} \\
T_{113} &= T_{123} = T_{223} = \frac{\pi(3(\eta - 1) + 12\eta\epsilon^2 - 2\epsilon^2)}{2b^2(\epsilon^2 - b^2)^2} \\
T_{133} &= T_{233} = \frac{2\pi(5 - 9\eta - 6\epsilon^2\eta)}{3(\epsilon^2 - 1)^2} \\
T_{333} &= \frac{4\pi(3\epsilon^2(5\eta - 1) - 2)}{15b^2\epsilon^2(\epsilon^2 - 1)^2}
\end{aligned} \tag{A.1}$$

where η is defined by:

$$\eta = \begin{cases} \frac{\epsilon}{(\epsilon^2 - 1)^{3/2}} \operatorname{arctanh} \left\{ \frac{\sqrt{\epsilon^2 - 1}}{\epsilon} \right\} - \frac{1}{\epsilon^2 - 1} & \text{(prolate spheroid)} \\ -\frac{\epsilon}{(1 - \epsilon^2)^{3/2}} \operatorname{arctan} \left\{ \frac{\sqrt{1 - \epsilon^2}}{\epsilon} \right\} + \frac{1}{1 - \epsilon^2} & \text{(oblate spheroid)} \end{cases} \tag{A.2}$$

The introduction of η allows to produce various equations which are valid for both the case of an oblate spheroid ($\epsilon \leq 1$) and a prolate spheroid ($\epsilon \geq 1$). The components of the sixth order Eshelby tensor, written in the canonical basis, are:

$$\begin{aligned}
s_1 &= \frac{(6 - 8\nu_0)(1 - p) - q}{8(1 - \nu_0)}, & s_2 &= p, \\
s_3 &= \frac{q + 8p(1 - \nu_0)}{4(1 - \nu_0)}\epsilon^2, & s_4 &= \frac{q + 4p(1 - \nu_0)}{4(1 - \nu_0)}, \\
s_5 &= \frac{q + 4p(1 - \nu_0)}{2(1 - \nu_0)}\epsilon^2, & s_6 &= \frac{1}{2} + \frac{q + p(1 - \nu_0)}{2(1 - \nu_0)}, \\
s_7 &= \frac{q + 4p}{2(1 - \nu_0)}\epsilon^2, & s_8 &= \frac{q + 2p(1 - \nu_0)}{2(1 - \nu_0)}, \\
s_9 &= -\frac{q + 2p(1 - \nu_0)}{2(1 - \nu_0)}\epsilon^2, & s_{10} &= \frac{q + 2p(1 + \nu_0)}{1 - \nu_0}\epsilon^2, \\
s_{11} &= 1 + \frac{q}{(1 - \nu_0)}, & s_{12} &= -\frac{q}{1 - \nu_0}\epsilon^2, \\
s_{13} &= \frac{2\nu_0 - (q + 2p + 4p\nu_0)\epsilon^2}{1 - \nu_0}, & s_{14} &= -\frac{q + 2p\nu_0}{(1 - \nu_0)}, \\
s_{15} &= 1 + \frac{q + 2p\nu_0}{1 - \nu_0}\epsilon^2, & s_{16} &= 1 - \frac{q + 4p(1 - \nu_0)}{4(1 - \nu_0)}, \\
s_{17} &= \frac{-q - 2p + 2}{4(1 - \nu_0)}, & s_{18} &= \frac{q - 2\nu_0(p - 1)}{4(1 - \nu_0)}, \\
s_{19} &= \frac{q + 4p(1 - \nu_0)}{2(1 - \nu_0)}\epsilon^2, & s_{20} &= -\frac{q}{8(1 - \nu_0)}, \\
s_{21} &= -\frac{q + 2(p - 1)}{8(1 - \nu_0)}, & s_{22} &= \frac{q - 2\nu_0(p - 1)}{8(1 - \nu_0)}, \\
s_{23} &= \frac{q}{1 - \nu_0}\epsilon^2, & s_{24} &= \frac{q + 2p\nu_0}{2(1 - \nu_0)}, \\
s_{25} &= \frac{q + 4p\nu_0}{2(1 - \nu_0)}, & s_{26} &= \frac{-q + 2p(1 - \nu_0)}{2(1 - \nu_0)}, \\
s_{27} &= -\frac{q + 2p\nu_0}{1 - \nu_0}\epsilon^2, & s_{28} &= -\frac{-q + p(\nu_0 - 3)}{2(1 - \nu_0)}, \\
s_{29} &= \frac{q + 2p(1 + \nu_0)}{2(1 - \nu_0)}, & s_{30} &= -\frac{q}{2(1 - \nu_0)}, \\
s_{31} &= 1 + \frac{-q + p(\nu_0 - 3)}{1 - \nu_0}\epsilon^2
\end{aligned} \tag{A.3}$$

in which p and q are two functions of the aspect ratio ϵ given by:

$$p = \frac{1 - 3\eta}{2(\epsilon^2 - 1)}, \quad q = \frac{3(\eta - 1) + 12\eta\epsilon^2 - 2\epsilon^2}{2(\epsilon^2 - b^2)^2} \tag{A.4}$$

In the case of cracks, the expansion series of p and q at $\epsilon = 0$ is:

$$p = 1 - \frac{3\pi}{4}\epsilon + o(\epsilon), \quad q = -\frac{3\pi}{4}\epsilon + o(\epsilon) \quad (\text{A.5})$$

The element of the compact representation of $\mathbb{Y}$ are $\{\beta, \beta, Y_1, Y_2, Y_3\}$ with:

$$\begin{aligned} Y_1 &= \begin{bmatrix} \beta & 0 \\ 0 & \beta \end{bmatrix}, \quad Y_2 = \frac{1}{3} \begin{bmatrix} 2\alpha + \beta & 0 & \alpha - \beta \\ 0 & 3\beta & 0 \\ \alpha - \beta & 0 & 2\alpha + \beta \end{bmatrix}, \\ Y_3 &= \frac{1}{3} \begin{bmatrix} 3\beta & 0 & 0 & 0 \\ \alpha - \beta & (2\alpha + \beta) & \alpha - \beta & 0 \\ \alpha - \beta & 2(\alpha - \beta) & 2\alpha + \beta & 0 \\ 0 & 0 & 0 & 3\beta \end{bmatrix} \end{aligned} \quad (\text{A.6})$$

The element of the compact representation of $\mathbb{C}^0$ are $\{2\mu_0, 2\mu_0, C_1^0, C_2^0, C_3^0\}$ with:

$$\begin{aligned} C_1^0 &= 2\mu_0 \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}, \quad C_2^0 = \frac{2\mu_0}{1 - 2\nu_0} \begin{bmatrix} 1 & 0 & \nu_0 \\ 0 & 1 - 2\nu_0 & 0 \\ \nu_0 & 0 & 1 \end{bmatrix}, \\ C_3^0 &= \frac{2\mu_0}{1 - 2\nu_0} \begin{bmatrix} 1 - 2\nu_0 & 0 & 0 & 0 \\ \nu_0 & 1 & \nu_0 & 0 \\ \nu_0 & 2\nu_0 & 1 & 0 \\ 0 & 0 & 0 & 1 - 2\nu_0 \end{bmatrix} \end{aligned} \quad (\text{A.7})$$

In the case of a cavity, the components of $\mathbb{A}$ are:

$$\begin{aligned}
a_1 &= \mu_0 \frac{2+q+(6-8\nu_0)p}{4(1-\nu_0)} & a_2 &= 2\mu_0(1-p) \\
a_3 &= 2\mu_0 - \mu_0 \frac{q+8p(1-\nu_0)}{2(1-\nu_0)} \epsilon^2 & a_4 &= -\mu_0 \frac{q+4p(1-\nu_0)}{2(1-\nu_0)} \\
a_5 &= -\mu_0 \frac{q+4p(1-\nu_0)}{1-\nu_0} \epsilon^2 & a_6 &= \mu_0 - \mu_0 \frac{q+p(1-\nu_0)}{1-\nu_0} \\
a_7 &= -\mu_0 \frac{(2(1+\nu_0)(2p\epsilon^2-1)+q\epsilon^2)}{1-\nu_0} & a_8 &= -\mu_0 \frac{q+2p(1+\nu_0)}{1-\nu_0} \\
a_9 &= \mu_0 \frac{q+2p(1+\nu_0)}{1-\nu_0} \epsilon^2 & a_{10} &= -2\mu_0 \frac{q+2p(1+\nu_0)}{1-\nu_0} \epsilon^2 \\
a_{11} &= -2\mu_0 \frac{q}{1-\nu_0} & a_{12} &= 2\mu_0 \frac{q}{1-\nu_0} \epsilon^2 \\
a_{13} &= 2\mu_0 \frac{q+2p(1+\nu_0)}{(1-\nu_0)} \epsilon^2 & a_{14} &= 2\mu_0 \frac{q}{1-\nu_0} \\
a_{15} &= -2\mu_0 \frac{q}{(1-\nu_0)} \epsilon^2 & a_{16} &= \mu_0 \frac{q+4p(1-\nu_0)}{2(1-\nu_0)} \\
a_{17} &= \mu_0 \frac{q+2(p-1)}{2(1-\nu_0)} & a_{18} &= \mu_0 \frac{-q+2(p-1)\nu_0}{2(1-\nu_0)} \\
a_{19} &= -\mu_0 \frac{q+4p(1-\nu_0)}{(1-\nu_0)} \epsilon^2 & a_{20} &= \mu_0 \frac{q+8p\nu_0}{4(1-\nu_0)} \\
a_{21} &= \mu_0 \frac{6+q+2p+8p\nu_0}{4(1-\nu_0)} & a_{22} &= -\mu_0 \frac{q+6(p-1)\nu_0}{4(1-\nu_0)} \\
a_{23} &= -\mu_0 \frac{q+8p\nu_0}{2(1-\nu_0)} \epsilon^2 & a_{24} &= -\mu_0 \frac{q}{1-\nu_0} \\
a_{25} &= -\mu_0 \frac{q+2(p-1)\nu_0}{(1-\nu_0)} & a_{26} &= \mu_0 \frac{q+2(1-p)}{1-\nu_0} \\
a_{27} &= 2\mu_0 \frac{q}{1-\nu_0} \epsilon^2 & a_{28} &= -\mu_0 \frac{q+p(3-\nu_0)}{(1-\nu_0)} \\
a_{29} &= -\mu_0 \frac{q+2p(1+\nu_0)}{(1-\nu_0)} & a_{30} &= \mu_0 \frac{q}{1-\nu_0} \\
a_{31} &= 2\mu_0 \frac{q+p(3-\nu_0)}{(1-\nu_0)} \epsilon^2 & &
\end{aligned} \tag{A.8}$$

In the case of a penny-shaped crack, the expansion series of a_n for $n = 1..31$ with respect to the aspect ratio ϵ can be obtained by replacing p and q by (A.4) in the above expressions.
