HAL is a multi-disciplinary open access archive for the deposit and dissemination of scientific research documents, whether they are published or not. The documents may come from teaching and research institutions in France or abroad, or from public or private research centers. L’archive ouverte pluridisciplinaire HAL, est destinée au dépôt et à la diffusion de documents scientifiques de niveau recherche, publiés ou non, émanant des établissements d’enseignement et de recherche français ou étrangers, des laboratoires publics ou privés.
ON THE INTERVAL OF STRONG PARTIAL CLONES OF BOOLEAN FUNCTIONS CONTAINING \( \text{Pol}\{(0,0), (0,1), (1,0)\} \)

MIGUEL COUCEIRO, LUCIEN HADDAD, KARSTEN SCHÖLZEL, AND TAMÁS WALDHÄUSER

Abstract. D. Lau raised the problem of determining the cardinality of the set of all partial clones of Boolean functions whose total part is a given Boolean clone. The key step in the solution of this problem, which was obtained recently by the authors, was to show that the sublattice of strong partial clones on \(\{0,1\}\) that contain all total functions preserving the relation \(\rho_{0,2} = \{(0,0), (0,1), (1,0)\}\) is of continuum cardinality. In this paper we represent relations derived from \(\rho_{0,2}\) in terms of graphs, and we define a suitable closure operator on graphs such that the lattice of closed sets of graphs is isomorphic to the dual of this uncountable sublattice of strong partial clones. With the help of this duality, we provide a rough description of the structure of this lattice, and we also obtain a new proof for its uncountability.

1. Introduction

Let \(A\) be a finite non-singleton set. Without loss of generality we assume that \(A = k := \{0, \ldots, k - 1\}\). For a positive integer \(n\), an \(n\)-ary partial function on \(k\) is a map \(f: \text{dom}(f) \to k\) where \(\text{dom}(f)\) is a subset of \(k^n\) called the domain of \(f\). If \(\text{dom}(f) = k^n\), then \(f\) is a total function (or operation) on \(k\). Let \(\text{Par}^{(n)}(k)\) denote the set of all \(n\)-ary partial functions on \(k\) and let \(\text{Par}(k) := \bigcup_{n \geq 1} \text{Par}^{(n)}(k)\). The set of all total operations on \(k\) is denoted by \(\text{Op}(k)\).

For \(n, m \geq 1\), \(f \in \text{Par}^{(n)}(k)\) and \(g_1, \ldots, g_n \in \text{Par}^{(m)}(k)\), the composition of \(f\) and \(g_1, \ldots, g_n\), denoted by \(f[g_1, \ldots, g_n] \in \text{Par}^{(m)}(k)\), is defined by

\[
\text{dom}(f[g_1, \ldots, g_n]) := \left\{ a \in k^m : a = \sum_{i=1}^{n} \text{dom}(g_i) \right\} 
\]

and

\[
f[g_1, \ldots, g_n](a) := f(g_1(a), \ldots, g_n(a))
\]

for all \(a \in \text{dom}(f[g_1, \ldots, g_n])\).

For every positive integer \(n\) and each \(1 \leq i \leq n\), let \(e_i^n\) denote the \(n\)-ary \(i\)-th projection function defined by \(e_i^n(a_1, \ldots, a_n) = a_i\) for all \((a_1, \ldots, a_n) \in k^n\). Furthermore, let

\[
J_k := \{ e_i^n : 1 \leq i \leq n \}
\]

be the set of all (total) projections on \(k\).

Definition 1.1. A partial clone on \(k\) is a composition closed subset of \(\text{Par}(k)\) containing \(J_k\).

The partial clones on \(k\), ordered by inclusion, form a complete lattice \(\mathcal{L}_{\text{Pa}}\) in which the infimum is the set-theoretical intersection. That means that the intersection of an arbitrary family of partial clones on \(k\) is also a partial clone on \(k\).

Waldhauser is supported by the Hungarian National Foundation for Scientific Research under grant no. K104251 and by the János Bolyai Research Scholarship.
Examples.
(1) \( \Omega_k := \bigcup_{n \geq 1} \{ f \in \text{Par}^{(n)}(k) : \text{dom}(f) \neq \emptyset \Rightarrow \text{dom}(f) = k^n \} \) is a partial clone on \( k \).

(2) For \( a = 0, 1 \) let \( T_a \) be the set of all total functions satisfying \( f(a, \ldots, a) = a \), let \( M \) be the set of all monotone total functions and \( S \) be the set of all self-dual total functions on \( 2 = \{0, 1\} \). Then \( T_0, T_1, M \) and \( S \) are (total) clones on \( 2 \).

(3) Let
\[
T_{0,2} := \{ f \in \text{Op}(2) : [(a_1, b_1) \neq (1, 1), \ldots, (a_n, b_n) \neq (1, 1)] \Rightarrow (f(a_1, \ldots, a_n), f(b_1, \ldots, b_n)) \neq (1, 1) \}.
\]
Then \( T_{0,2} \) is a (total) clone on \( 2 \).

(4) Let
\[
\tilde{S} := \{ f \in \text{Par}(2) : [(a_1, \ldots, a_n), (\neg a_1, \ldots, \neg a_n)] \subseteq \text{dom}(f) \Rightarrow f(\neg a_1, \ldots, \neg a_n) = \neg f(a_1, \ldots, a_n) \},
\]
where \( \neg \) is the negation on \( 2 \). Then \( \tilde{S} \) is a partial clone on \( 2 \).

Definition 1.2. For \( h \geq 1 \), let \( \rho \) be an \( h \)-ary relation on \( k \) and \( f \) be an \( n \)-ary partial function on \( k \). We say that \( f \) preserves \( \rho \) if for every \( h \times n \) matrix \( M = [M_{ij}] \) whose columns \( M_{ij} \in \rho \) (\( j = 1, \ldots, n \)) and whose rows \( M_{is} \in \text{dom}(f) \) (\( i = 1, \ldots, h \)), the \( h \)-tuple \( (f(M_{1s}), \ldots, f(M_{hs})) \in \rho \). Define
\[
p\text{Pol}(\rho) := \{ f \in \text{Par}(k) : f \text{ preserves } \rho \}.
\]

It is well known that \( p\text{Pol} \) is a partial clone called the partial clone determined by the relation \( \rho \). Note that if there is no \( h \times n \) matrix \( M = [M_{ij}] \) whose columns \( M_{ij} \in \rho \) and whose rows \( M_{is} \in \text{dom}(f) \), then \( f \in p\text{Pol}(\rho) \). We can naturally extend the \( p\text{Pol} \) operator to sets of relations: if \( \mathcal{R} \) is a set of relations, then \( p\text{Pol}(\mathcal{R}) = \bigcap_{\rho \in \mathcal{R}} p\text{Pol}(\rho) \). We denote the total part of \( p\text{Pol}(\mathcal{R}) \) by \( \text{Pol}(\mathcal{R}) \), i.e., \( \text{Pol}(\mathcal{R}) = p\text{Pol}(\mathcal{R}) \cap \text{Op}(k) \).

We say that \( g \in \text{Par}(k) \) is a subfunction of \( f \in \text{Par}(k) \) if \( \text{dom}(g) \subseteq \text{dom}(f) \) and \( g \) is the restriction of \( f \) to \( \text{dom}(g) \).

Definition 1.3. A strong partial clone is a partial clone that is closed under taking subfunctions.

A partial clone is strong if and only if it contains all partial projections (subfunctions of projections). For a set \( P \subseteq \text{Par}(k) \) we denote the least strong partial clone containing \( P \) by \( \text{Str}(P) \). Observe that if \( C \subseteq \text{Op}(k) \) is a total clone, then \( \text{Str}(C) \) is just the set of all subfunctions of members of \( C \). It is easy to see that if a partial function \( f \) preserves a relation \( \rho \), then all subfunctions of \( f \) also preserve \( \rho \). Thus every partial clone of the form \( p\text{Pol}(\rho) \) is strong.

In the examples above \( T_a = \text{Pol}(\{a\}) \), \( M = \text{Pol}(\leq) \), \( S = \text{Pol}(\neq) \), \( T_{0,2} = \text{Pol}(\rho_{0,2}) \) and \( \tilde{S} = p\text{Pol}(\neq) \), whereas \( \Omega_k \) is not a strong partial clone. Here, for simplicity, we write \( \leq \) for \( \{\{0,0\}, \{0,1\}, \{1,1\}\} \), \( \rho_{0,2} \) for \( \{\{0,0\}, \{0,1\}, \{1,0\}\} \) and \( \neq \) for \( \{\{0,1\}, \{1,0\}\} \).

The study of partial clones on \( 2 := \{0, 1\} \) was initiated by R. V. Freivald [8]. Among other things, he showed that the set of all monotone partial functions and the set of all self-dual partial functions are both maximal partial clones on \( 2 \). In fact, Freivald showed that there are exactly eight maximal partial clones on \( 2 \). To state Freivald’s result, we introduce the following two relations: let
\[
R_1 = \{ (x, x, y, y) : x, y \in 2 \} \cup \{ (x, y, y, x) : x, y \in 2 \}
\]
\[
R_2 = R_1 \cup \{ (x, y, x, y) : x, y \in 2 \}.
\]

Theorem 1.4 (8). There are 8 maximal partial clones on \( 2 \): \( p\text{Pol}(\{0\}) \), \( p\text{Pol}(\{1\}) \), \( p\text{Pol}(\leq) \), \( p\text{Pol}(\neq) \), \( p\text{Pol}(R_1) \), \( p\text{Pol}(R_2) \) and \( \Omega_2 \).

Note that the set of total functions preserving \( R_2 \) form the maximal clone of all (total) linear functions over \( 2 \).
Also interesting is to determine the intersections of maximal partial clones. It is shown in [1] that the set of all partial clones on 2 that contain the maximal clone consisting of all total linear functions on 2 is of continuum cardinality (for details see [1] and Theorem 20.7.13 of [17]). A consequence of this is that the interval of partial clones \([pPol(R_2) \cap \Omega_2, \Par(2)]\) is of continuum cardinality.

A similar result, (but slightly easier to prove) is established in [10] where it is shown that the interval of partial clones \([pPol(R_1) \cap \Omega_2, \Par(2)]\) is also of continuum cardinality. Notice that the three maximal partial clones \(pPol R_1\), \(pPol R_2\) and \(\Omega_2\) contain all unary functions (i.e., maps) on 2. Such partial clones are called \(\textit{Slupecki type}\) partial clones in \([11, 21]\). These are the only three maximal partial clones of Slupecki type on 2.

For a complete study of the pairwise intersections of all maximal partial clones of Slupecki type on a finite non-singleton set \(k\), see [11]. The papers \([12, 13, 18, 23, 24]\) focus on the case \(k = 2\) where various interesting, and sometimes hard to obtain, results are established. For instance, the intervals

\[
[pPol(\{0\}) \cap pPol(\{1\}) \cap pPol(\{(0, 1)\}) \cap pPol(\leq), \Par(2)]
\]

and

\[
[pPol(\{0\}) \cap pPol(\{1\}) \cap pPol(\{(0, 1)\}) \cap pPol(\neq), \Par(2)]
\]

are shown to be finite and are completely described in [12]. Some of the results in [12] are included in [23, 24] where partial clones on 2 are handled via the one point extension approach (see section 20.2 in [17]).

In view of results from [1, 10, 12, 23, 24], it was thought that if \(2 \leq i \leq 5\) and \(M_1, \ldots, M_i\) are non-Slupecki maximal partial clones on 2, then the interval \([M_1 \cap \cdots \cap M_i, \Par(2)]\) is either finite or countably infinite. It was shown in [13] that the interval of partial clones \([\text{pPol}(\leq) \cap \text{pPol}(\neq), \Par(2)]\) is infinite. However, it remained an open problem to determine whether \([\text{pPol}(\leq) \cap \text{pPol}(\neq), \Par(2)]\) is countably or uncountably infinite. This problem was settled in [3]:

**Theorem 1.5** ([3]). The interval of partial clones \([\text{pPol}(\leq) \cap \text{pPol}(\neq), \Par(2)]\) that contain the strong partial clone of monotone self-dual partial functions, is of continuum cardinality on 2.

The main construction in proving this result was later adapted in [3] to solve an intrinsically related problem that was first considered by D. Lau [16], and tackled recently by several authors, namely: Given a total clone \(C\) on 2, describe the interval of all partial clones on 2 whose total component is \(C\). Let us introduce a notation for this interval and several variants:

\[
\mathcal{I}(C) := \{ P \subseteq \Par(2) : P \text{ is a partial clone and } C = P \cap \Op(2) \};
\]

\[
\mathcal{I}_{\text{Str}}(C) := \{ P \subseteq \Par(2) : P \text{ is a strong partial clone and } C = P \cap \Op(2) \};
\]

\[
\mathcal{I}_{\text{Str}}^C(\Par(2)) := \{ P \subseteq \Par(2) : P \text{ is a strong partial clone and } C \subseteq P \cap \Op(2) \}.
\]

In [3] we established a complete classification of all intervals of the form \(\mathcal{I}(C)\), for a total clone \(C\) on 2, and showed that each such \(\mathcal{I}(C)\) is either finite or of continuum cardinality. Given the previous results by several authors, the missing case was settled by the following theorem. (Note that \(\mathcal{I}(T_{0,2}) \supseteq \mathcal{I}_{\text{Str}}(T_{0,2})\), hence if \(\mathcal{I}_{\text{Str}}(T_{0,2})\) has continuum cardinality, then it follows that \(\mathcal{I}(T_{0,2})\) is also uncountable.)

**Theorem 1.6** ([3]). The interval of strong partial clones \(\mathcal{I}_{\text{Str}}(T_{0,2})\) is of continuum cardinality.

Lau’s problem is equivalent to the problem of determining the cardinalities of intervals of weak relational clones generating a given relational clone (see Subsection 2.1). This problem is important in the study of complexity of constraint satisfaction problems (CSPs), and has been posed in [15].

In this paper we provide an alternative proof of Theorem 1.6 based on a representation of relations that are invariant under \(T_{0,2}\) by graphs. By defining an appropriate closure operator on graphs, we will show that there are a continuum of such closed sets of graphs,
which in turn are in a one-to-one correspondence with strong partial clones containing $T_{0.2}$. As we will see, this construction will contribute to a better understanding of the structure of this uncountable sublattice of partial clones.

This paper is organised as follows. In Section 2 we recall some basic notions and preliminary results on relations and graphs that will be needed throughout. In Section 3 we introduce a representation of relations by graphs, and we show that the lattice $\mathcal{I}_{\text{Str}}^{\leq}(T_{0.2})$ is dually isomorphic to the lattice of classes of graphs that are closed under some natural constructions such as disjoint unions and quotients. Motivated by this duality, in Section 4 we introduce a representation of relations by graphs, and we show that the lattice of classes of graphs that are closed under some natural constructions such as disjoint unions and quotients. Motivated by this duality, in Section 4 and Section 5 we focus on this lattice of closed sets of graphs, and obtain some results about its structure. These results (after dualizing) yield the following information about $\mathcal{I}_{\text{Str}}^{\leq}(T_{0.2})$:

(a) $\mathcal{I}_{\text{Str}}^{\leq}(T_{0.2})$ has a two-element chain at the bottom and a three-element chain at the top (Theorem 1.4);

(b) between these chains there is an uncountable “jungle” (see Figure 1), in which there is a continuum of elements below and above every element (Theorems 5.15 and 5.21);

(c) for each $n \in \{0, 1, 2, \ldots, 80\}$, there exist elements in $\mathcal{I}_{\text{Str}}^{\leq}(T_{0.2})$ with exactly $n$ lower covers (Theorem 5.13).

This paper is an extended version of the conference paper [5] presented at the 44th IEEE International Symposium on Multiple-Valued Logic, where (a) has been proved as well as a weaker form of (b).

2. Preliminaries

2.1. Relations. An $n$-ary relation $\rho \subseteq k^n$ over $k$ can be regarded as a map $k^n \to \{0, 1\}$, such that $\rho(a_1, \ldots, a_n)$ is 1 iff $(a_1, \ldots, a_n) \in \rho$. This allows us to speak about inessential coordinates: the $i$-th coordinate of $\rho$ is inessential if the corresponding map $k^n \to \{0, 1\}$ does not depend on its $i$-th variable. Sometimes it will be convenient to think of a relation $\rho$ as an $n \times |\rho|$ matrix, whose columns are the tuples belonging to $\rho$ (the order of the columns is irrelevant).

For a set $\mathcal{R}$ of relations, let $\langle \mathcal{R} \rangle_\rho$ denote the set of relations definable by quantifier-free primitive positive formulas over $\mathcal{R} \cup \{\omega_k\}$, where $\omega_k = \{(a, a) : a \in k\}$ is the equality relation on $k$. Formally, an $n$-ary relation $\sigma$ belongs to $\langle \mathcal{R} \rangle_\rho$ if and only if there exist relations $\rho_1, \ldots, \rho_t \in \mathcal{R} \cup \{\omega_k\}$ of arities $r_1, \ldots, r_t$, respectively, and there are variables $z_{ij} \in \{x_1, x_2, \ldots, x_n\}$ ($j = 1, \ldots, t; i = 1, \ldots, r_j$) such that

$$\sigma(x_1, \ldots, x_n) = \bigwedge_{j=1}^t \rho_j(z_{1j}, \ldots, z_{r_j}).$$

We say that $\mathcal{R}$ is a weak relational clone if $\mathcal{R}$ is closed under quantifier-free primitive positive definability, i.e., $\langle \mathcal{R} \rangle_\rho = \mathcal{R}$. (The terms weak partial co-clone and weak co-clone are also used for this notion.)

Let $\text{Inv}(P)$ denote the set of invariant relations of a set $P \subseteq \text{Par}(k)$ of partial functions:

$$\text{Inv}(P) := \{\rho \subseteq k^n : \rho \text{ is preserved by each } f \in P\}.$$  

The operators $\text{pPol}$ and $\text{Inv}$ give rise to a Galois connection between partial functions and relations, and the corresponding Galois closed classes are strong partial clones and weak relational clones.

Theorem 2.1 ([20]). For any set $P \subseteq \text{Par}(k)$ of partial functions and for any set $\mathcal{R}$ of relations on $k$, we have

$$\text{Str}(P) = \text{pPol Inv}(P) \quad \text{and} \quad \langle \mathcal{R} \rangle_\rho = \text{Inv pPol}(\mathcal{R}).$$

Remark 2.2. Theorem 2.1 implies that the lattice of strong partial clones is dually isomorphic to the lattice of weak relational clones. In particular, for any total Boolean clone $C$, the interval $\mathcal{I}_{\text{Str}}(C)$ is dually isomorphic to the interval $\{\mathcal{R} : \langle \mathcal{R} \rangle_\rho = \mathcal{R} \text{ and } \text{Pol}(\mathcal{R}) = C\}$ in the lattice of weak relational clones.
Now we introduce some simple constructions for relations that allow us to give an alternative description of the closure $⟨R⟩_R$.

- For $ρ ⊆ k^n$ and $σ ⊆ k^m$, the direct product of $ρ$ and $σ$ is the relation $ρ × σ ⊆ k^{n+m}$ defined by
  $$ρ × σ = \{(a_1, \ldots, a_{n+m}) ∈ k^{n+m} : (a_1, \ldots, a_n) ∈ ρ, (a_{n+1}, \ldots, a_{n+m}) ∈ σ\}.$$
- Let $ρ ⊆ k^n$ and let $ε$ be an equivalence relation on $\{1, 2, \ldots, n\}$. Define $Δ_ε(ρ) ⊆ k^n$ by
  $$Δ_ε(ρ) = \{(a_1, \ldots, a_n) ∈ ρ : a_i = a_j \text{ whenever } (i, j) ∈ ε\}.$$

We say that $Δ_ε(ρ)$ is obtained from $ρ$ by diagonalization.

- If two relations $ρ$ and $σ$, considered as matrices, can be obtained from each other by permuting rows, by adding or deleting repeated rows, and by adding or deleting inessential coordinates, then a partial function $f$ preserves $ρ$ if and only if $f$ preserves $σ$. In this case we say that $ρ$ and $σ$ are essentially the same, and we write $ρ ≈ σ$. Observe that the relations $k$ (binary total relation) and $ω_k$ (binary equality relation) are essentially the same.

The following characterization of weak relational clones is straightforward to verify.

**Fact 2.3.** For an arbitrary set $R$ of relations on $k$, we have $⟨R⟩_R = R$ if and only if the following conditions are satisfied:

(i) if $ρ, σ ∈ R$, then $ρ × σ ∈ R$;
(ii) if $ρ ∈ R$, then $Δ_ε(ρ) ∈ R$ (for all appropriate equivalence relations $ε$);
(iii) $k ∈ R$ (here $k$ is the unary total relation);
(iv) if $ρ, σ ∈ R$ and $σ ≈ ω_k$, then $σ ∈ R$.

2.2. Graphs. We consider finite undirected graphs without multiple edges. For any graph $G$, let $V(G)$ and $E(G)$ denote the set of vertices and edges of $G$, respectively. An edge $uv ∈ E(G)$ is called a loop if $u = v$. A map $ϕ : V(G) → V(H)$ is a homomorphism from $G$ to $H$ if for all $uv ∈ E(G)$ we have $ϕ(u)ϕ(v) ∈ E(H)$. We use the notation $G → H$ to denote the fact that there is a homomorphism from $G$ to $H$. The homomorphic image of $G$ under $ϕ$ is the subgraph $ϕ(G)$ of $H$ given by $V(ϕ(G)) = \{ϕ(v) : v ∈ V(G)\}$ and $E(ϕ(G)) = \{ϕ(u)ϕ(v) : uv ∈ E(G)\}$. If $ϕ(G)$ is an induced subgraph of $H$, then we say that $ϕ$ is a faithful homomorphism; this means that every edge of $H$ between two vertices in $ϕ(V(G))$ is the image of an edge of $G$ under $ϕ$. If $ϕ : G → H$ is a surjective faithful homomorphism, then $ϕ$ is said to be a complete homomorphism. In this case $H$ is the homomorphic image of $G$ under $ϕ$ (i.e., $H = ϕ(G)$), and we shall denote this by $G → H$.

If $ε$ is an equivalence relation on the set of vertices $V(G)$ of a graph $G$, then we can form the quotient graph $G/ε$ as follows: the vertices of $G/ε$ are the equivalence classes of $ε$, and two such equivalence classes $C, D$ are connected by an edge in $G/ε$ if and only if there exist $u ∈ C, v ∈ D$ such that $uv ∈ E(G)$. Note that a vertex of $G/ε$ has no loop if and only if the corresponding equivalence class is an independent set in $G$ (i.e., there are no edges inside this equivalence class in $G$). There is a canonical correspondence between quotients and homomorphic images: the quotient $G/ε$ is a homomorphic image of $G$ (under the natural homomorphism sending every vertex to the $ε$-class to which it belongs), and if $ϕ : G → H$ is a complete homomorphism, then $H$ is isomorphic to the quotient of $G$ corresponding to the kernel of $ϕ$.

For $n ∈ N$, the complete graph $K_n$ is the graph on $n$ vertices that has no loops but has an edge between any two distinct vertices, i.e.,

$$E(K_n) = \{uv : u, v ∈ V(K_n) \text{ and } u ≠ v\}.$$

Note that this defines $K_n$ only up to isomorphism (as the vertex set is not specified). In fact, in the following we will not distinguish between isomorphic graphs. For $n = 1$ we get the graph $K_1$ consisting of a single isolated vertex. We will denote the one-vertex graph with a loop by $L$. 
The disjoint union of graphs $G$ and $H$ will be denoted by $G \oplus H$. Observe that there exist natural homomorphisms $G \rightarrow G \oplus H$ and $H \rightarrow G \oplus H$. By $k \cdot G := G \oplus \cdots \oplus G$ we denote the disjoint union of $k$ copies of $G$.

A homomorphism $G \rightarrow K_n$ is a proper coloring of $G$ by $n$ colors (regard the vertices of $K_n$ as $n$ different colors; properness means that adjacent vertices of $G$ must receive different colors). The chromatic number $\chi (G)$ of a loopless graph is the least number of colors required in a proper coloring of $G$. Observe that if $G \rightarrow H$, then $\chi (G) \leq \chi (H)$, since $G \rightarrow H \rightarrow K_n$ implies $G \rightarrow K_n$ for all natural numbers $n$. A graph is bipartite if and only if $\chi (G) \leq 2$, i.e., $G$ is 2-colorable.

The girth of a graph is the length of its shortest cycle (if there is a cycle at all), and the odd girth of a graph is the length of the shortest cycle of odd length in $G$ (is there is an odd cycle at all, i.e., if $G$ is not bipartite). The odd girth can be described in terms of homomorphisms as follows. Let $C_n$ denote the cycle of length $n$ without loops (just like $K_n$, this graph is defined only up to isomorphism). Then the odd girth of a non-bipartite graph $G$ is the least odd number $n$ such that $C_n \rightarrow G$. It follows that if $G \rightarrow H$, then the odd girth of $H$ is at most as large as the odd girth of $G$. P. Erdős has proved that for any pair of natural numbers $(k, g)$ with $k, g \geq 3$ there exists a graph with chromatic number $k$ and girth $g$ [17].

Since the relation $\rightarrow$ is reflexive and transitive, it is a quasiorder on the set of all (isomorphism types of) finite graphs. The corresponding equivalence relation is called homomorphic equivalence, and factoring out by this equivalence, we obtain the homomorphism order of graphs. The above mentioned theorem of Erdős implies that this homomorphism order has infinite width: if $G_k$ is a graph with chromatic number and odd girth equal to $2k + 1$ for each $k \in \mathbb{N}$, then $\{G_1, G_2, \ldots \}$ is an infinite antichain. The homomorphism order is dense almost everywhere: E. Welzl showed that if $G$ is strictly less than $H$ (that is $G \rightarrow H$ and $H \nrightarrow G$), then there exists a graph lying between $G$ and $H$, except in the case when $G$ and $H$ are homomorphically equivalent to $K_1$ and $K_2$, respectively [23].

Let $G$ denote the set of (isomorphism types of) finite undirected graphs without multiple edges and without isolated vertices. We make one exception to the ban on isolated vertices: we include the one-point graph $K_1$ in $G$. We allow loops, and a vertex having a loop is not considered as isolated; in particular, $L \in G$. In Section 3 we will work only with loopless non-bipartite graphs, so let us introduce the notation $G_1$ for the set of loopless non-bipartite members of $G$. Observe that no graph from $G_1$ is homomorphically equivalent to $K_1$ or $K_2$, hence Welzl’s theorem implies that $G_1$ is a dense quasiordered set. We shall need the following strengthening of this density result.

**Theorem 2.4** ([19]). If $G, H \in G_1$ such that $G \rightarrow H$ and $H \nrightarrow G$, then there exists an infinite antichain $\{T_1, T_2, \ldots \} \subseteq G_1$ between $G$ and $H$, i.e., $G \rightarrow T_i \rightarrow H$ and $T_i \nrightarrow T_j$ for all $i, j \in \mathbb{N}, i \neq j$.

### 3. Representing relations in $(\rho_{0,2})_\#$ by graphs

Recall that $\rho_{0,2}$ is the binary relation $\rho_{0,2} = \{0, 1\}^2 \setminus \{(1, 1)\}$ on $2$, and $T_{0,2} = \text{Pol} (\rho_{0,2})$ is the corresponding total clone. The interval $\mathcal{I}_{\text{Str}} (T_{0,2})$ is dually isomorphic to the interval $\{R : \langle R \rangle_\# = \mathcal{R} \text{ and } T_{0,2} \subseteq \text{pol} (\mathcal{R})\}$ in the lattice of weak relational clones (cf. Remark 2.2). According to the next proposition, this latter interval is in turn isomorphic to the lattice of weak relational subclones of $(\rho_{0,2})_\#$.

**Proposition 3.1.** For any weak relational clone $\mathcal{R}$ on $2$, we have $T_{0,2} \subseteq \text{Pol} (\mathcal{R})$ if and only if $\mathcal{R} \subseteq (\rho_{0,2})_\#$.

**Proof.** The condition $T_{0,2} \subseteq \text{pol} (\mathcal{R})$ is equivalent to $\text{Str} (T_{0,2}) \subseteq \text{pPol} (\mathcal{R})$, whereas $\mathcal{R} \subseteq (\rho_{0,2})_\#$ is equivalent to $\text{pPol} (\rho_{0,2}) \subseteq \text{pPol} (\mathcal{R})$. Therefore, it suffices to prove that $\text{pPol} (\rho_{0,2}) = \text{Str} (T_{0,2})$, i.e., that if a partial function $f$ preserves $\rho_{0,2}$, then it extends to a total function $\tilde{f}$ still preserving $\rho_{0,2}$. It is easy to see that setting $\tilde{f} (a) = 0$ for all $a \notin \text{dom} (f)$ gives the required extension of $f$. \qed
Let us write $\text{Sub}(\langle \rho_{0,2} \rangle_\beta)$ for the lattice of weak relational clones contained in $\langle \rho_{0,2} \rangle_\beta$. By Proposition 3.1, $\text{Sub}(\langle \rho_{0,2} \rangle_\beta)$ is dually isomorphic to $\mathcal{I}_{\text{Str}}(T_{0,2})$. Since the only Boolean clones properly containing $T_{0,2}$ are $T_0$ and $\text{Op}(2)$, we have $\mathcal{I}_{\text{Str}}(T_{0,2}) = \mathcal{I}_{\text{Str}}(T_0) \cup \mathcal{I}_{\text{Str}}(\text{Op}(2))$. The intervals $\mathcal{I}_{\text{Str}}(T_0)$ and $\mathcal{I}_{\text{Str}}(\text{Op}(2))$ are singletons (see [1]), but we will also reprove these facts in Remark 4.5, hence the main task is to describe the structure of $\mathcal{I}_{\text{Str}}(T_{0,2})$.

We will represent relations in $\langle \rho_{0,2} \rangle_\beta$ by graphs, and we will introduce an appropriate closure operator on graphs such that the closed sets of graphs are in a one-to-one correspondence with the $\langle \rho_{0,2} \rangle_\beta$-closed subsets of $\langle \rho_{0,2} \rangle_\beta$. This will allow us to give a simple proof for the uncountability of $\mathcal{I}_{\text{Str}}(T_{0,2})$ and to obtain some new results about the structure of this lattice.

If $G \in \mathcal{G}$ is a graph with $V(G) = \{v_1, \ldots, v_n\}$, then we can define a relation $\text{rel}(G) \subseteq 2^n$ by

$$\text{rel}(G) \langle x_1, \ldots, x_n \rangle = \bigwedge_{v_i v_j \in E(G)} \rho_{0,2}(x_i, x_j).$$

Note that if we enumerate the vertices of $G$ in a different way, then we may obtain a different relation; however, these two relations differ only in the order of their rows, hence they are essentially the same. Clearly, $\text{rel}(G) \in \langle \rho_{0,2} \rangle_\beta$ for every $G \in \mathcal{G}$; moreover, for any $\sigma \in \langle \rho_{0,2} \rangle_\beta$ there exists $G \in \mathcal{G}$ such that $\sigma$ and $\text{rel}(G)$ are essentially the same. Indeed, $\sigma \in \langle \rho_{0,2} \rangle_\beta$ implies that $\sigma$ is of the form

$$\sigma(x_1, \ldots, x_n) = \bigwedge_{j=1}^t \rho_{0,2}(x_{u_j}, x_{v_j}) \land \bigwedge_{j=t+1}^s (x_{u_j} = x_{v_j}),$$

where $u_j, v_j \in \{1, 2, \ldots, n\}$ ($j = 1, \ldots, s$). Now if we define a graph $G$ by $V(G) = \{1, 2, \ldots, n\}$ and

$$E(G) = \{u_1 v_1, \ldots, u_s v_s\},$$

then we have $\sigma \approx \text{rel}(G/\varepsilon)$, where $\varepsilon$ is the least equivalence relation on $V(G)$ that contains the pairs $(u_{t+1}, v_{t+1}), \ldots, (u_s, v_s)$. Removing isolated vertices (if there are any) from $G/\varepsilon$, we obtain a graph $G' \in \mathcal{G}$ such that $\sigma \approx \text{rel}(G')$. (Recall that isolated vertices are not allowed in $\mathcal{G}$ with the sole exception of $K_1$. This does not result in a loss of generality, since isolated vertices in a graph $H$ correspond to inessential coordinates in the relation $\text{rel}(H)$.)

It may happen that nonisomorphic graphs induce essentially the same relation. This is captured by the following equivalence relation. Let us say that the graphs $G, H \in \mathcal{G}$ are loopvivalent (notation: $G \circ H$) if the following two conditions are satisfied:

- $G$ has a loop if and only if $H$ has a loop;
- the subgraphs spanned by the edges connecting loopless vertices in $G$ and $H$ are isomorphic.

**Remark 3.2.** Observe that for loopless graphs loopvivalence is equivalent to isomorphy. If $G$ has a loop, then we can obtain a canonical representative of the loopvivalence class of $G$ as follows. Delete all looped vertices from $G$, and if any of the remaining vertices become isolated, then delete these isolated vertices, too. Denoting the resulting (loopless) graph by $G^*$, we have $G \circ G^* \subseteq L$; furthermore, $G^* \subseteq L$ is the “simplest” graph that is loopvivalent to $G$. As an example, consider a graph $G$ on two vertices, which are connected by an edge, and at least one of them has a loop. Then $G^*$ is empty (cf. [1]), hence $G$ is loopvivalent to $L$.

**Lemma 3.3.** For any $G, H \in \mathcal{G}$, we have $\text{rel}(G) \approx \text{rel}(H) \iff G \circ H$.

**Proof.** Let $G \in \mathcal{G}$ be an arbitrary graph with $V(G) = \{v_1, \ldots, v_n\}$. Since $\rho_{0,2} = 2^2 \setminus \{(1,1)\}$, a tuple $a = (a_1, \ldots, a_n) \in 2^n$ belongs to $\text{rel}(G)$ if and only if $a^{-1}(1) := \{v_i : a_i = 1\} \subseteq V(G)$ is an independent set. Thus the tuples in $\text{rel}(G)$ are in a one-to-one correspondence with the independent sets of $G$. Therefore, for any $G, H \in \mathcal{G}$ with $V(G) = V(H) = \{v_1, \ldots, v_n\}$, we have $\text{rel}(G) = \text{rel}(H)$ if and only if $G$ and $H$ have the
same independent sets. This holds if and only if $G$ and $H$ have the same loops and they have the same edges between loopless vertices. Indeed, a vertex $v_i$ has a loop if and only if the set $\{v_i\}$ is not independent, and there is an edge between loopless vertices $v_i$ and $v_j$ if and only if the set $\{v_i, v_j\}$ is not independent. Moreover, edges between a looped vertex and any other vertex are irrelevant in determining independent sets, since a set containing a looped vertex can never be independent.

Now let us determine the possible repeated rows of the matrix of rel ($G$). If two vertices $v_i$ and $v_j$ both have a loop, then the $i$-th and the $j$-th rows of the matrix of rel ($G$) are identical (in fact, they are constant 0, as a looped vertex cannot belong to any independent set). On the other hand, if, say, $v_i$ does not have a loop, then $\{v_i\}$ is an independent set, and the corresponding tuple $a \in \text{rel}(G)$ satisfies $1 = a_i \neq a_j = 0$, hence the $i$-th and the $j$-th rows of the matrix of rel ($G$) are different. Thus the matrix of rel ($G$) has repeated rows if and only if $G$ has more than one loop, and in this case the repeated rows are the constant 0 rows corresponding to the looped vertices.

From the above considerations it follows that for any $G, H \in \mathcal{G}$ we have rel ($G$) $\approx$ rel ($H$) if and only if $G \cap H$.

Now let us translate the four conditions of Fact 2.3 to an appropriate closure operator on $\mathcal{G}$. Let us say that a set $K \subseteq G$ of graphs is $\approx$-closed if it is closed under disjoint unions, homomorphic images and loopvivalance, and contains $K_1$:

(i) if $G, H \in K$, then $G \oplus H \in K$;
(ii) if $G \in K$ and $G \approx H$, then $H \in K$;
(iii) $K_1 \in K$;
(iv) if $G \in K$ and $G \approx H$, then $H \in K$.

The $\approx$-closure of $K \subseteq \mathcal{G}$ is the smallest $\approx$-closed set $\langle K \rangle _\approx$ that contains $K$. Let us denote the lattice of $\approx$-closed subsets of $\mathcal{G}$ by $\text{Sub} (\mathcal{G})$. Later we shall also need another closure operator on loopless graphs, which we call $\cong$-closure. We say that a set $K \subseteq \mathcal{G}_1$ is $\cong$-closed if it is closed under disjoint unions and loopless homomorphic images:

(i) if $G, H \in K$, then $G \oplus H \in K$;
(ii) if $G \in K$ and $G \approx H$, then $H \in K$, provided that $H$ has no loops.

The least $\cong$-closed subset of $\mathcal{G}_1$ containing $K$ will be denoted by $\langle K \rangle _\cong$.

The next lemma gives a visual interpretation of $\cong$-closure that we will often use in the sequel: a graph $G$ belongs to $\langle K \rangle _\cong$ if and only if $G$ can be built by “gluing together” loopless homomorphic images of members of $K$.

**Lemma 3.4.** For arbitrary $K \subseteq \mathcal{G}_1$ and $G \in \mathcal{G}_1$ the following three conditions are equivalent:

(i) $G \in \langle K \rangle _\cong$;
(ii) $H_1 \oplus \cdots \oplus H_k \rightarrow G$ for some $k \in \mathbb{N}$ and $H_1, \ldots, H_k \in K$;
(iii) every edge of $G$ is contained in a subgraph that is a homomorphic image of a member of $K$.

**Proof.** It is easy to see that a disjoint union of quotients of some graphs is also a quotient of the disjoint union of these graphs, thus (i) $\implies$ (ii). To prove (ii) $\implies$ (iii), suppose that $H_1, \ldots, H_k \in K$ and $\varphi: H_1 \oplus \cdots \oplus H_k \rightarrow G$ is a complete homomorphism, and let $e$ be an arbitrary edge of $G$. By completeness of $\varphi$, the edge $e$ is contained in $\varphi(H_i)$ for some $i$, and then $\varphi(H_i)$ is the required subgraph of $G$.

Finally, for (iii) $\implies$ (i), assume that for every edge $e \in E(G)$ there is a (not necessarily induced) subgraph $S_e$ of $G$ that is the homomorphic image of some member of $K$ and $e \in E(S_e)$. Clearly, this implies $S_e \in \langle K \rangle _\cong$, so it suffices to prove that $G \in \{\langle S_e: e \in E(G) \rangle \}_\cong$. Let $\iota_e: S_e \rightarrow G$ be the inclusion map for every $e \in E(G)$, and let us combine these maps into a homomorphism $\varphi: \bigoplus_{e \in E(G)} S_e \rightarrow G$. Since $e$ is included in the image of $S_e$, the homomorphism $\varphi$ is complete, and this shows that $G$ indeed belongs to the $\cong$-closure of $\{S_e: e \in E(G)\}$.
Remark 3.5. Note that the (proof of) implication (iii) $\implies$ (i) of Lemma 3.4 applies also to $\triangleright$-closure. As an illustration, observe that any graph without isolated vertices can be built from edges and looped vertices, hence $G = (K_2, L)_{\triangleright} = (K_2)_{\triangleright}$ (we can omit $L$ as it is a homomorphic image of $K_2$).

As the main result of this section, we prove that $\triangleright$-closure is indeed the appropriate closure operator on $G$ that reflects the structure of the lattices $\text{Sub}(\langle \rho_0, 2 \rangle_\triangleright)$ and $\mathcal{I}_{\text{Str}}(T_{0, 2})$.

Proposition 3.6. The lattice $\text{Sub}(\langle \rho_0, 2 \rangle_\triangleright)$ of weak relational subclones of $\langle \rho_0, 2 \rangle_\triangleright$ is isomorphic to the lattice $\text{Sub}(G)$ of $\triangleright$-closed subsets of $G$.

Proof. For $K \subseteq G$ and $R \subseteq \langle \rho_0, 2 \rangle_\triangleright$, let

$$\Phi(K) = \{ \sigma \in \langle \rho_0, 2 \rangle_\triangleright : \exists G \in K \text{ such that } \sigma \approx \text{rel}(G) \};$$

$$\Psi(R) = \{ G \in G : \text{rel}(G) \in R \}.$$

Observe that $\text{rel}(G \uplus H) \approx \text{rel}(G) \times \text{rel}(H)$ and $\text{rel}(G/\varepsilon) \approx \Delta_x(\text{rel}(G))$ for all $G, H \in G$ and for every equivalence relation $\varepsilon$ on $V(G)$, and we have $\text{rel}(K_1) \approx 2$. Using these observations it is straightforward to verify that $\langle K \rangle_{\triangleright} = K \implies \langle \Phi(K) \rangle_{\triangleright} = \Phi(K)$ and $\langle R \rangle_{\triangleright} = R \implies \langle \Psi(R) \rangle_{\triangleright} = \Psi(R)$. Thus we have obtained maps $\Phi : \text{Sub}(G) \to \text{Sub}(\langle \rho_0, 2 \rangle_\triangleright)$ and $\Psi : \text{Sub}(\langle \rho_0, 2 \rangle_\triangleright) \to \text{Sub}(G)$, and it is clear that both maps are order-preserving. Therefore, it only remains to show that $\Phi$ and $\Psi$ are inverses of each other: for every $K \subseteq \text{Sub}(G)$ and $R \subseteq \text{Sub}(\langle \rho_0, 2 \rangle_\triangleright)$ we have

$$\Phi \Psi(K) = \{ G \in G : \text{rel}(G) \in \Phi(K) \} = \{ G \in G : \exists H \in K \text{ such that } \text{rel}(G) \approx \text{rel}(H) \} = \{ G \in G : \exists H \in K \text{ such that } G \triangleright H \} = K;$$

$$\Psi \Phi(R) = \{ \sigma \in \langle \rho_0, 2 \rangle_\triangleright : \exists G \in \Psi(R) \text{ such that } \sigma \approx \text{rel}(G) \} = \{ \sigma \in \langle \rho_0, 2 \rangle_\triangleright : \exists G \in G \text{ such that } \text{rel}(G) \in R \text{ and } \sigma \approx \text{rel}(G) \} = R.$$

Corollary 3.7. The lattice $\mathcal{I}_{\text{Str}}(T_{0, 2})$ of strong partial clones containing $T_{0, 2}$ is dually isomorphic to the lattice $\text{Sub}(G)$ of $\triangleright$-closed subsets of $G$ (see Figure 1).

4. The Bottom and the Top of $\text{Sub}(G)$

Building upon Corollary 3.7 in the rest of the paper we study the lattice of $\triangleright$-closed subsets of $G$. In this section we take a closer look at the bottom and the top of the lattice: we prove that there is a 3-element chain at the bottom and a 2-element chain at the top of $\text{Sub}(G)$; see Figure 1. Between these chains there is a “jungle” that embeds the power set of a countably infinite set, hence it has continuum cardinality. We shall explore this jungle in Section 5.

The smallest $\triangleright$-closed subset of $G$ is $\langle \emptyset \rangle_{\triangleright} = \langle K_1 \rangle_{\triangleright} = \{ K_1 \}$. Any graph containing an edge has $L$ (the graph having only one vertex with a loop on it) as a homomorphic image, hence the second smallest $\triangleright$-closed set is $\langle L \rangle_{\triangleright}$, which consists of all graphs having a loop and no edges between loopless vertices. In the next lemma we prove that the third smallest $\triangleright$-closed subset of $G$ is $\langle K_2 \oplus L \rangle_{\triangleright}$. It is easy to see with the help of Remark 3.5 that $\langle K_2 \oplus L \rangle_{\triangleright} \setminus \{ K_1 \}$ is the set of all graphs containing at least one loop.

Lemma 4.1. At the bottom of the lattice $\text{Sub}(G)$ we have the three-element chain $\langle K_1 \rangle_{\triangleright} < \langle L \rangle_{\triangleright} < \langle K_2 \oplus L \rangle_{\triangleright}$. All other $\triangleright$-closed subsets of $G$ contain $\langle K_2 \oplus L \rangle_{\triangleright}$.

Proof. Let $K \subseteq G$ be a $\triangleright$-closed set such that $\langle L \rangle_{\triangleright} \subset K$. Then $K$ contains a graph $G$ with an edge $uv$ where $u$ and $v$ are distinct loopless vertices. Let us form the disjoint union $G \oplus L$, and let us identify all vertices of this graph except for $u$ and $v$. Then we obtain a graph $G' \in K$ with $V(G') = \{ u, v, w \}$ and $\{ u, v, w \} \subset E(G') \subset \{ u, v, w, uw, vw \}$. 
Deleting the edges \( uv \) and \( vw \) (if they are present) we arrive at a graph \( G'' \) with \( V(G'') = \{u, v, w\} \) and \( E(G'') = \{uw, vw\} \). Since \( G'' \) is isomorphic to \( K_2 \oplus L \), we have \( G'' \in \mathcal{K} \); moreover, \( G'' \) is isomorphic to \( K_2 \oplus L \), hence \( \langle K_2 \oplus L \rangle \subseteq \mathcal{K} \). This proves that \( \langle K_2 \oplus L \rangle \) is the third smallest \( \triangleleft \)-closed subset of \( \mathcal{G} \). \( \square \)

As we will see later, we have to stop our climbing up in the lattice here, as there is no fourth smallest \( \triangleleft \)-closed set, so let us now focus on the top of the lattice \( \text{Sub}(\mathcal{G}) \). The largest \( \triangleleft \)-closed set is clearly \( \mathcal{G} \), which, as we observed in Remark 3.5, can be generated by \( K_2 \). The following lemma describes the second largest \( \triangleleft \)-closed set (recall that \( \mathcal{G}_1 \) denotes the set of all loopless non-bipartite members of \( \mathcal{G} \)).

**Lemma 4.2.** At the top of the lattice \( \text{Sub}(\mathcal{G}) \) we have the two-element chain \( \mathcal{G} = \langle K_2 \rangle \triangleright \langle K_2 \oplus L \rangle \cup \mathcal{G}_1 \). All other \( \triangleleft \)-closed subsets of \( \mathcal{G} \) are contained in \( \langle K_2 \oplus L \rangle \cup \mathcal{G}_1 \).

**Proof.** Let us consider a \( \triangleleft \)-closed set \( \mathcal{K} \) such that \( \langle K_2 \oplus L \rangle \subseteq \mathcal{K} \). If \( \mathcal{K} \) contains a graph \( G \) that is bipartite and has at least one edge (which cannot be a loop, because of bipartiteness), then we have \( G \triangleright K_2 \in \mathcal{K} \). Then we can conclude \( \mathcal{K} \supseteq \langle K_2 \rangle = \mathcal{G} \) (cf. Remark 3.5). Thus every proper \( \triangleleft \)-closed subset of \( \mathcal{G} \) must be contained in \( \langle K_2 \oplus L \rangle \cup \mathcal{G}_1 \). It remains to show that the set \( \langle K_2 \oplus L \rangle \cup \mathcal{G}_1 \) is \( \triangleleft \)-closed. To verify this, one just needs to observe that if at least one of \( G \) and \( H \) is not bipartite, then \( G \oplus H \) is not bipartite either; furthermore, if \( G \) is not bipartite and \( G \triangleright H \), then \( H \) is not bipartite either (otherwise we would have \( G \triangleright H \rightarrow K_2 \), hence \( G \rightarrow K_2 \), contradicting the non-bipartiteness of \( G \)). Therefore, the second largest \( \triangleleft \)-closed subset of \( \mathcal{G} \) is indeed \( \langle K_2 \oplus L \rangle \cup \mathcal{G}_1 \). \( \square \)

We will see in the next section that there is no third largest \( \triangleleft \)-closed subset of \( \mathcal{G} \), therefore we finish our climbing down here and summarize our findings in the following theorem.

**Theorem 4.3.** A set \( \mathcal{K} \subseteq \mathcal{G} \) is \( \triangleleft \)-closed if and only if either

(i) \( \mathcal{K} = \langle K_1 \rangle = \{K_1\} \), or

(ii) \( \mathcal{K} = \langle L \rangle \), or

(iii) \( \mathcal{K} = \langle K_2 \rangle = \mathcal{G} \), or

(iv) \( \mathcal{K} = \langle K_2 \oplus L \rangle \cup \mathcal{H} \), where \( \mathcal{H} \subseteq \mathcal{G}_1 \) is \( \triangleright \)-closed.
Proof. By Lemmas [1.1] and [1.2] the sets listed in the first three items are \( \circ \)-closed (as well as the fourth item with \( \mathcal{H} = \emptyset \) and \( \mathcal{H} = \mathcal{G}_1 \)); moreover, any other \( \circ \)-closed set \( \mathcal{K} \) satisfies \( (K_2 \oplus L) \cup \mathcal{G}_1 \subseteq \mathcal{K} \subseteq (K_2 \oplus L) \cup \mathcal{G}_1 \). Let \( \mathcal{K} \) be such a set, and let \( \mathcal{H} \subseteq \mathcal{G}_1 \) be the set of all loopless non-bipartite members of \( \mathcal{K} \); then we have \( \mathcal{K} = (K_2 \oplus L) \cup \mathcal{H} \). To finish the proof, one just has to verify that \( \mathcal{K} \) is \( \circ \)-closed if and only if \( \mathcal{H} \) is closed under disjoint unions and loopless homomorphic images.

We conclude this section with the description of the bottom and the top of \( I_{\text{Str}}(T_{0,2}) \). It is immediate from Theorem 4.3 and Corollary 3.7 that there is a three-element chain at the top, and a two-element chain at the bottom of \( I_{\text{Str}}(T_{0,2}) \). In the next theorem we describe explicitly the five strong partial clones in these chains.

**Theorem 4.4.** At the top of the lattice \( I_{\text{Str}}(T_{0,2}) \) we have a three-element chain \( \text{Par(2)} \supset \text{Str}(T_0) \supset \text{Str}(T_{0,2}) \cup \{f \in \text{Par(2)} : (0, \ldots, 0) \notin \text{dom}(f)\} \), while at the bottom we have the two-element chain \( \text{Str}(T_{0,2}) \prec \text{Str}(T_{0,2}) \cup \{g\} \), where \( g \) is the binary partial function defined by \( \text{dom}(g) = \{(0, 1), (1, 0)\} \) and \( g(0, 1) = g(1, 0) = 1 \). All other strong partial clones in \( I_{\text{Str}}(T_{0,2}) \) lie between these two chains (see Figure 2).

Proof. We just need to translate the results of Lemma 1.1 and Lemma 1.2 to the lattice \( \text{Sub}(\{\rho_{0,2}\}) \) with the help of Proposition 3.6 and then pass to the lattice \( I_{\text{Str}}(T_{0,2}) \) by the operator \( p\text{Pol} \) (note that this last step turns the lattice upside down).

It is obvious that \( \Phi((K_1)_{\circ}) = (\mathbf{2})_{\circ} \) is the trivial relational clone, and the corresponding strong partial clone is \( p\text{Pol}(\mathbf{2}) = \text{Par}(2) \). Similarly, since \( \text{rel}(L) \) is the unary relation \( \{0\} \), we have \( \Phi((L)_{\circ}) = \{(0, 1)\}_{\circ} \), and \( p\text{Pol}(\{0\}) = \text{Str}(T_0) \). The relation corresponding to \( K_2 \oplus L \) is

\[ \text{rel}(K_2 \oplus L) = \{(0, 0, 0), (0, 1, 0), (1, 0, 0)\} = \rho_{0,2} \times \{0\} \]

All partial functions with \( (0, \ldots, 0) \notin \text{dom}(f) \) automatically preserve this relation, and it is straightforward to verify that if \( (0, \ldots, 0) \in \text{dom}(f) \), then \( f \in p\text{Pol}(\rho_{0,2} \times \{0\}) \) holds if and only if \( f \in p\text{Pol}(\rho_{0,2}) = \text{Str}(T_{0,2}) \).

For the chain at the bottom, observe that \( \text{rel}(K_2) = \rho_{0,2} \), thus we have \( \Phi((K_2)_{\circ}) = (\rho_{0,2})_{\circ} \), and the corresponding strong partial clone is clearly \( p\text{Pol}(\rho_{0,2}) = \text{Str}(T_{0,2}) \). Finally, let us consider the strong partial clone \( \mathcal{C} := p\text{Pol}(\Phi((K_2 \oplus L)_{\circ} \cup \mathcal{G}_1)) \). The function \( g \) defined in the statement of the theorem does not preserve \( \rho_{0,2} \), therefore \( \text{Str}(T_{0,2}) \subset \text{Str}(T_{0,2} \cup \{g\}) \). It follows from Theorem 4.3 that \( \mathcal{C} \) is the unique upper cover of \( \text{Str}(T_{0,2}) \), hence it suffices to verify that \( \text{Str}(T_{0,2} \cup \{g\}) \subseteq \mathcal{C} \), i.e., that \( g \) preserves \( \text{rel}(K_2 \oplus L) \) and \( \text{rel}(G) \) for all \( G \in \mathcal{G}_1 \). The former is trivial, as \( (0, 0) \notin \text{dom}(f) \). For the latter, let us consider an arbitrary non-bipartite graph \( G \) with \( V(G) = \{v_1, \ldots, v_n\} \), and let \( a, b \in \{0, 1\}^n \) such that \( a, b \in \text{rel}(G) \) and \( (a, b) \in \text{dom}(g) \) for every \( i \). Since \( \text{dom}(g) = \{(0, 1), (1, 0)\} \), the sets \( a^{-1}(1) \) and \( b^{-1}(1) \) form a partition of \( V(G) \), and both sets are independent by the definition of \( \text{rel}(G) \) (cf. the proof of Lemma 3.3). However, this means that \( G \) is 2-colorable, contradicting the non-bipartiteness of \( G \). Thus Definition 1.2 is satisfied emptyly: there is no matrix \( M \) such that its columns belong to \( \text{rel}(G) \) and its rows belong to \( \text{dom}(g) \).

**Remark 4.5.** The total parts of \( \text{Par}(2) \) and \( \text{Str}(T_0) \) are \( \text{Op}(2) \) and \( T_0 \), while the total part of \( \text{Str}(T_{0,2}) \cup \{f \in \text{Par(2)} : (0, \ldots, 0) \notin \text{dom}(f)\} \) is \( T_{0,2} \). Therefore, we have \( I_{\text{Str}}(\text{Op}(2)) = \{\text{Par}(2)\} \) and \( I_{\text{Str}}(T_0) = \{\text{Str}(T_0)\} \), while \( I_{\text{Str}}(T_{0,2}) \) can be obtained from \( I_{\text{Str}}(T_{0,2}) \) by removing these two elements from the top of the lattice.

5. The jungle

After Theorem 4.3, it remains to describe the structure of the interval

\[ [(K_2 \oplus L)_{\circ}, (K_2 \oplus L)_{\circ} \cup \mathcal{G}_1] \]

of \( \text{Sub}(\mathcal{G}) \). By Theorem 4.3, the map \( (K_2 \oplus L)_{\circ} \cup \mathcal{H} \mapsto \mathcal{H} \) is an isomorphism from this interval to the lattice of \( \circ \)-closed subsets of \( \mathcal{G}_1 \), which we shall denote by \( \text{Sub}(\mathcal{G}_1) \). Therefore, in this section we focus on the lattice \( \text{Sub}(\mathcal{G}_1) \). Thus, in the sequel we will
assume that all homomorphisms map to loopless graphs; in particular, we never identify vertices connected by an edge. We will prove several properties of \( \text{Sub}(G) \) indicating that this lattice is quite complicated, hence it deserves to be called a jungle.

5.1. **Decomposing the jungle.** Let us consider the partition \( G_1 = A \cup B \), where

\[
A = \{ G \in G_1 : \text{all components of } G \text{ are non-bipartite} \}, \\
B = \{ G \in G_1 : \text{at least one component of } G \text{ is bipartite} \}.
\]

Observe that \( \langle A \rangle_\cup = A \), but \( B \) is not \( \cup \)-closed. In this subsection we show that for any \( H \subseteq G_1 \), one can determine \( \langle H \rangle_\cup \) by computing the \( \cup \)-closure of \( H \cap A \) and \( H \cap B \) separately; moreover, \( \langle H \cap B \rangle_\cup \) is particularly easy to describe, since it is just an upset in the homomorphism order of graphs (see Theorem 5.4). As a corollary, we obtain that \( \text{Sub}(G_1) \) can be embedded into the direct product of the lattice of \( \cup \)-closed subsets of \( A \) and the lattice of upsets of the quasiordered set \((A; \rightarrow)\) (see Corollary 5.8). First we introduce some notation, and then we prove some preparatory results about the connection between \( \cup \)-closure and upsets.

For any graph \( H \in G_1 \), let \( H_A \in A \) be the sum of the non-bipartite components of \( H \). If \( H \in A \) then \( H_A = H \), whereas for \( H \in B \) we have \( H = H_A \oplus B \) with some bipartite graph \( B \). Note that \( H_A \) is never empty, as every graph in \( G_1 \) is non-bipartite. For a set \( H \subseteq G_1 \), let \( H^\uparrow \) denote the upset generated by \( H \) in the quasiordered set \((G_1; \rightarrow)\), i.e., let \( H^\uparrow = \{ G \in G_1 : H \rightarrow G \text{ for some } H \in H \} \).

**Lemma 5.1.** For every \( H \subseteq G_1 \), we have \( \langle H \rangle_\cup \subseteq H^\uparrow \); consequently, if \( H \subseteq G_1 \) is an upset in \((G_1; \rightarrow)\), then \( \langle H \rangle_\cup = H \).

**Proof.** If \( G \in \langle H \rangle_\cup \), then, by Lemma 5.4, there is a complete homomorphism \( \varphi : H_1 \oplus \cdots \oplus H_k \rightarrow G \) for some \( k \in \mathbb{N} \) and \( H_1, \ldots, H_k \in H \). Restricting \( \varphi \) to \( H_1 \), we get a homomorphism (not necessarily complete) \( H_1 \rightarrow G \), which shows that \( G \in H^\uparrow \). If \( H \) is an upset, then \( \langle H \rangle_\cup \subseteq H^\uparrow = H \), therefore \( \langle H \rangle_\cup = H \). \hfill \Box

**Remark 5.2.** It follows from Lemma 5.1 that if \( \{ H_1, H_2, \ldots \} \subseteq G_1 \) is an infinite antichain in the homomorphism order, then the map \( I \mapsto \{ H_i : i \in I \} \) embeds the power set of \( \mathbb{N} \) into \( \text{Sub}(G_1) \). As mentioned in Subsection 2.2 such antichains do exist, hence \( \text{Sub}(G_1) \) has continuum cardinality.

**Lemma 5.3.** For every \( H \in B \), the graphs \( H \) and \( H_A \oplus K_2 \) are homomorphically equivalent, and \( \langle H \rangle_\cup = \langle H_A \oplus K_2 \rangle_\cup = H^\uparrow \).

**Proof.** Let \( H \in B \), and let us consider the decomposition \( H = H_A \oplus B \), where \( B \) is the sum of the bipartite components of \( H \). Since \( H \) has no isolated vertices, \( B \) has at least one edge, hence \( K_2 \rightarrow B \), and also \( B \rightarrow K_2 \), as \( B \) is bipartite. This implies that the graphs \( H = H_A \oplus B \) and \( H_A \oplus K_2 \) are homomorphically equivalent.

For the other statements of the lemma, let us verify the following chain of containments:

\[
(H_A \oplus K_2)^\uparrow \subseteq \langle H_A \oplus K_2 \rangle_\cup \subseteq \langle H \rangle_\cup \subseteq H^\uparrow.
\]

To prove the first containment, let \( G \in G_1 \) such that \( H_A \oplus K_2 \rightarrow G \); then there is also a homomorphism \( \varphi : H_A \rightarrow G \). For every edge \( e = uv \in E(G) \), let \( S_e \) denote the subgraph of \( G \) that is obtained by adding the edge \( e \) to \( \varphi(H_A) \): \( V(S_e) = V(\varphi(H_A)) \cup \{ u, v \} \) and \( E(S_e) = E(\varphi(H_A)) \cup \{ e \} \). We can extend \( \varphi \) to a homomorphism \( \varphi \circ : H_A \oplus K_2 \rightarrow S_e \) that maps the edge of \( K_2 \) onto \( e \). This shows that condition (iii) of Lemma 5.4 is satisfied with \( H = \{ H_A \oplus K_2 \} \), therefore \( G \in \langle H_A \oplus K_2 \rangle_\cup \).

The second containment of (5.1) follows from the fact that \( H_A \oplus K_2 \) is a homomorphic image of \( H = H_A \oplus B \), since \( B \rightarrow K_2 \). The third containment is immediate from Lemma 5.1.

To finish the proof, recall that \( H \) and \( H_A \oplus K_2 \) are homomorphically equivalent, hence \( (H_A \oplus K_2)^\uparrow = H^\uparrow \), and then all containments of (5.1) are actually equalities. \hfill \Box
Theorem 5.4. For every set $\mathcal{H} \subseteq \mathcal{G}_1$, we have

$$\langle \mathcal{H} \rangle \not\leftrightarrow = \langle \mathcal{H} \cap \mathcal{A} \rangle \not\leftrightarrow \cup \langle \mathcal{H} \cap \mathcal{B} \rangle \not\leftrightarrow.$$

Proof. If $G \in \langle \mathcal{H} \rangle \not\leftrightarrow$, then $H_1 \oplus \cdots \oplus H_k \rightarrow G$ for some $k \in \mathbb{N}$ and $H_1, \ldots, H_k \in \mathcal{H}$, by Lemma 3.4. If $H_i \in \mathcal{A}$ for every $i$, then $G \in \langle \mathcal{H} \cap \mathcal{A} \rangle \not\leftrightarrow$. Otherwise there is an $i$ such that $H_i \in \mathcal{B}$, and then $H_i \rightarrow G$. This proves that $\langle \mathcal{H} \rangle \not\leftrightarrow \subseteq \langle \mathcal{H} \cap \mathcal{A} \rangle \not\leftrightarrow \cup \langle \mathcal{H} \cap \mathcal{B} \rangle \not\leftrightarrow$.

For the reverse containment, let us suppose that $G \in \langle \mathcal{H} \cap \mathcal{A} \rangle \not\leftrightarrow \cup \langle \mathcal{H} \cap \mathcal{B} \rangle \not\leftrightarrow$. If $G \in \langle \mathcal{H} \cap \mathcal{A} \rangle \not\leftrightarrow$, then we have obviously $G \in \langle \mathcal{H} \rangle \not\leftrightarrow$, as $\langle \mathcal{H} \cap \mathcal{A} \rangle \not\leftrightarrow \subseteq \langle \mathcal{H} \rangle \not\leftrightarrow$. Otherwise there exists $H \in \mathcal{H} \cap \mathcal{B}$ such that $H \rightarrow G$. It follows from Lemma 5.3 that $G \in \langle H \rangle \not\leftrightarrow$, and then $G \in \langle \mathcal{H} \rangle \not\leftrightarrow$. □

Remark 5.5. In view of Lemma 5.3, we may identify the graphs $H$ and $H \oplus K_2$ for every $H \in \mathcal{B}$, when investigating homomorphisms and $\not\leftrightarrow$-closed sets in $\mathcal{G}_1$, i.e., we can assume without loss of generality that the bipartite components (if any) of our graphs are always $K_2$. Therefore, we will write subsets of $\mathcal{B}$ in the form $H \oplus K_2 := \{H \oplus K_2 : H \in \mathcal{H}\}$ with $\mathcal{H} \subseteq \mathcal{A}$. In particular, we have $\mathcal{B} = \mathcal{A} \oplus K_2$. (If one does not wish to make the aforementioned identification, then $\mathcal{H} \oplus K_2$ should be interpreted as the set of all graphs of the form $H \oplus B$, where $H \in \mathcal{H}$ and $B$ is a bipartite graph without isolated vertices.)

Theorem 5.6. A set $\mathcal{H} \subseteq \mathcal{G}_1$ is $\not\leftrightarrow$-closed if and only if there exist $\mathcal{H}_1, \mathcal{H}_2 \subseteq \mathcal{A}$ such that

(i) $\mathcal{H} = \mathcal{H}_1 \cup \mathcal{H}_2 \oplus K_2$;
(ii) $\mathcal{H}_1$ is $\not\leftrightarrow$-closed;
(iii) $\mathcal{H}_2$ is an upset (order filter) in $(\mathcal{A}; \rightarrow)$, i.e., $\mathcal{H}_2 \uparrow \mathcal{A} = \mathcal{H}_2$;
(iv) $\mathcal{H}_2 \subseteq \mathcal{H}_1$.

Proof. Let us put $\mathcal{H}_1 = \mathcal{H} \cap \mathcal{A}$, and let $\mathcal{H}_2$ denote the collection of the non-bipartite parts of the members of $\mathcal{H} \cap \mathcal{B}$, i.e., $\mathcal{H}_2 = \{H_A : H \in \mathcal{H} \cap \mathcal{B}\}$. Then, performing the identification of Remark 5.5 we have $\mathcal{H} \cap \mathcal{B} = \mathcal{H}_2 \oplus K_2$, hence $\mathcal{H} = \mathcal{H}_1 \cup \mathcal{H}_2 \oplus K_2$. For every graph $G$ with at least one edge, $G$ and $G \oplus K_2$ are homomorphically equivalent; therefore, $(\mathcal{H} \cap \mathcal{B}) \uparrow = (\mathcal{H}_2 \oplus K_2) \uparrow = \mathcal{H}_2 \uparrow \mathcal{A}$. By the same token, we have $\mathcal{H}_1 \cap \mathcal{B} = (\mathcal{H}_2 \cap \mathcal{A}) \oplus K_2$.

By Theorem 5.4 and by the above observations, we have

$$\langle \mathcal{H} \rangle \not\leftrightarrow = \langle \mathcal{H}_1 \rangle \not\leftrightarrow \cup \mathcal{H}_2 \oplus K_2 = \langle \mathcal{H}_1 \rangle \not\leftrightarrow \cup (\mathcal{H}_2 \cap \mathcal{A}) \oplus K_2.$$

Figure 2. The structure of a $\not\leftrightarrow$-closed subset of $\mathcal{G}_1$
Both cases of Theorem 5.10 do appear: if \( \langle H \rangle \nrightarrow A \) and \( \langle H \rangle \nrightarrow B \), then the interval \( \langle H \rangle \nrightarrow A \implies \langle H \rangle \nrightarrow B \). From Definition 5.2 we see that \( \langle H \rangle \nrightarrow B = (H_1 \cap A)^{\oplus K_2} \), thus \( \langle H \rangle \nrightarrow A \subseteq H \nrightarrow B \iff (H_1 \cap A)^{\oplus K_2} \subseteq H_2^{\oplus K_2} \implies H_1 \cap A \subseteq H_2 \), which is equivalent to (iii). Again from Definition 5.2 we have \( \langle H \rangle \nrightarrow A = \langle H_1 \rangle \nrightarrow (H_2 \cap A) \), hence \( \langle H \rangle \nrightarrow A \subseteq \langle H \rangle \nrightarrow A \iff \langle H_1 \rangle \nrightarrow H_1 \text{ and } H_2 \cap A \subseteq H_1 \), which, taking (iii) also into account, is equivalent to (ii) and (iv).

**Remark 5.7.** The structure of \( \nrightarrow \)-closed subsets of \( G_1 \) as described by Theorem 5.6 can be visualized as follows (see Figure 2): we take an upset \( H_2 \in (A; \rightarrow) \); then the interval \( \langle H \rangle \nrightarrow A \) contains two comparable graphs: there exist \( H_1 \in \langle H \rangle \nrightarrow A \text{ and } H_2 \cap A \subseteq H_1 \), depending on whether \( K_2 \cap H_2 \) is finite or has continuum cardinality.

**Corollary 5.8.** The lattice \( \text{Sub} (G_1) \) is isomorphic to the sublattice \( \{ \langle H_1, H_2 \rangle : H_2 \subseteq H_1 \} \subseteq \text{Sub} (A) \times \text{Upsets} (A) \) of the direct product of the lattice of \( \nrightarrow \)-closed subsets of \( A \) and the lattice of upsets of the quasiordered set \( (A; \rightarrow) \).

**Theorem 5.9.** The interval \( [A, G_1] \) in \( \text{Sub} (G_1) \) is isomorphic to \( \text{Upsets} (A) \).

**Proof.** Using the notation of Theorem 5.6 the map \( H \mapsto H_2 \) establishes the required isomorphism.

Observe that the union of two upsets is an upset, hence the lattice \([A, G_1] \) is distributive. Building upon the isomorphism given in Theorem 5.9 we show that each subinterval of \([A, G_1] \) is either finite or has continuum cardinality.

**Theorem 5.10.** If \( H \) and \( K \) are \( \nrightarrow \)-closed subsets of \( G_1 \) such that \( A \subseteq H \subset K \), then the interval \( [H, K] \) is either a finite Boolean lattice or it embeds the power set of \( \mathbb{N} \).

**Proof.** According to Theorem 5.9 we can work in the lattice \( \text{Upsets} (A) \); let \( H_2 \) and \( K_2 \) be the upsets corresponding to \( H \) and \( K \). Assume first that the difference \( K_2 \setminus H_2 \) contains two comparable graphs: there exist \( G, H \in K_2 \setminus H_2 \) such that \( G \rightarrow H \) and \( H \rightarrow G \). By Theorem 2.4 there is an infinite antichain between \( G \) and \( H \), i.e., there are graphs \( T_1, T_2, \ldots \) such that \( G \rightarrow T_i \rightarrow H \) and \( T_i \) and \( T_j \) are incomparable for all \( i, j \in \mathbb{N}, i \neq j \). For every set \( S \subseteq \mathbb{N} \) we can construct an upset \( U_S = H_2 \cup \{ T_i : i \in S \} \), and it is straightforward to verify that the map \( S \mapsto U_S \) embeds the power set of \( \mathbb{N} \) into the interval \( [H_2, K_2] \) of the lattice of upsets of \( (A; \rightarrow) \).

Now let us assume that \( K_2 \setminus H_2 \) contains no comparable elements, i.e., it is an antichain. Then the interval \( [H_2, K_2] \) is isomorphic to the power set of \( K_2 \setminus H_2 \). Depending on whether \( K_2 \setminus H_2 \) is finite or infinite, we obtain either a finite Boolean lattice or the power set of \( \mathbb{N} \).

**Remark 5.11.** Both cases of Theorem 5.10 do appear: if \( G, H \in A \) are such that \( G \rightarrow H \) and \( H \rightarrow G \), then the interval \( [H^\uparrow, G^\downarrow] \) in \( \text{Upsets} (A) \) embeds the power set of \( \mathbb{N} \), while if \( T_1, \ldots, T_n \) is an antichain in \( A \) then the interval between \( H = T_1^\uparrow \cup \cdots \cup T_n^\uparrow \setminus \{ T_1, \ldots, T_n \} \) and \( K = T_1^\downarrow \cup \cdots \cup T_n^\downarrow \) is isomorphic to the power set of \( \{ 1, \ldots, n \} \).

**Corollary 5.12.** Every interval above \( A \) in \( \text{Sub} (G_1) \) is either finite or has continuum cardinality.
Theorem 5.13. For each $n \in \{0,1,2,\ldots,\aleph_0\}$, there exist elements in $\text{Sub}(G_1)$ with exactly $n$ upper covers.

Proof. By Theorem 5.9, if $\mathcal{H} \subseteq \mathcal{A}$ has $n$ upper covers in $\text{Upsets}(\mathcal{A})$, then $\mathcal{A} \cup \mathcal{H}^{\oplus K_2}$ has $n$ upper covers in the lattice of $\varpi$-closed subsets of $G_1$. For $n = 0$ let us take an infinite ascending chain $G_1 \rightarrow G_2 \rightarrow \ldots$ in $\mathcal{A}$ (for example, let $G_i = K_{i+2}$), and let $\mathcal{U} = \{H \in \mathcal{A}: H \rightarrow G_i \text{ for every } i \in \mathbb{N}\}$; this is clearly an upper set. If $\mathcal{V}$ is an upper set such that $\mathcal{U} \subseteq \mathcal{V}$ and $\mathcal{H} \in \mathcal{V} \setminus \mathcal{U}$, then $H \rightarrow G_i$ for some $i \in \mathbb{N}$. This implies that $G_i \in \mathcal{V}$, thus $\mathcal{U} \subseteq \mathcal{U} \cup G_i^\uparrow \subseteq \mathcal{V}$. Therefore, $\mathcal{V}$ is not an upper cover of $\mathcal{U}$, hence $\mathcal{U}$ has no upper covers.

For $n \in \{1,2,\ldots,\aleph_0\}$, let $\{G_i: i \in I\}$ be an antichain in $\mathcal{A}$ of size $n$. Let us define $\mathcal{U}$ in the same way as above: $\mathcal{U} = \{H \in \mathcal{A}: H \rightarrow G_i \text{ for every } i \in I\}$. Then $\mathcal{U}$ is an upper set and $\mathcal{U} \cup \{G_i\}$ covers $\mathcal{U}$ for every $i \in I$. Moreover, if $\mathcal{V}$ is an upper set with $\mathcal{U} \subseteq \mathcal{V}$, then $\mathcal{U} \cup \{G_i\} \subseteq \mathcal{V}$ for some $i \in I$. Indeed, for any element $H \in \mathcal{V} \setminus \mathcal{U}$, we have $H \rightarrow G_i$ for some $i \in I$, hence $G_i \in \mathcal{V}$, as $\mathcal{V}$ is an upper set. This shows that the only covers of $\mathcal{U}$ are $\mathcal{U} \cup \{G_i\}$ $(i \in I)$. □

Remark 5.14. Choosing the ascending chain $K_3 \rightarrow K_4 \rightarrow \ldots$ in the first half of the proof of Theorem 5.13, we obtain $\mathcal{U} = \emptyset$, since every finite graph has a finite chromatic number. This shows that the empty set has no upper cover in $\text{Upsets}(\mathcal{A})$, consequently $\mathcal{A} \cup \emptyset^{\oplus K_2} = \mathcal{A}$ has no upper cover in $\text{Sub}(G_1)$.

To conclude this subsection, we prove, as promised in Section 4, that $\langle K_2 \oplus L \rangle_\varpi \cup G_1$ has no lower covers in $\text{Sub}(\mathcal{G})$, or, equivalently, that $G_1$ has no lower covers in $\text{Sub}(G_1)$. Actually, we shall prove more: no matter how small a step we take downwards from $G_1$, we already have passed an uncountable part of the jungle.

Theorem 5.15. For every $\varpi$-closed set $\mathcal{H} \subset G_1$, the interval $[\mathcal{H}, G_1]$ has continuum cardinality.

Proof. Let us consider the decomposition $\mathcal{H} = \mathcal{H}_1 \cup \mathcal{H}_2^{\oplus K_2}$ as in Theorem 5.6. If $\mathcal{H}_2 = \mathcal{A}$, then also $\mathcal{H}_1 = \mathcal{A}$, since $\mathcal{H}_1 \supseteq \mathcal{H}_2$, and then $\mathcal{H} = \mathcal{A} \cup \mathcal{A}^{\oplus K_2} = \mathcal{A} \cup B = G_1$ (cf. Remark 5.5), contrary to our assumption.

Thus $\mathcal{H}_2 \subset \mathcal{A}$, hence $\mathcal{A} \cup \mathcal{H}_2^{\oplus K_2} \subset G_1$; moreover, $\mathcal{A} \cup \mathcal{H}_2^{\oplus K_2}$ is $\varpi$-closed by Theorem 5.6. Let $G \in \mathcal{A} \setminus \mathcal{H}_2$, and let $H \in \mathcal{A}$ be a graph below $G$, i.e., $H \rightarrow G$ and $G \rightarrow H$ (for example, let $H = C_{g+2}$, where $g$ is the odd girth of $G$). Since $G \notin \mathcal{H}_2$ and $\mathcal{H}_2$ is an upset, it follows that $H \notin \mathcal{H}_2$. Therefore, $\mathcal{A} \setminus \mathcal{H}_2$ contains two comparable graphs (namely $G$ and $H$), and then (the proof of) Theorem 5.10 shows that there is a continuum of $\varpi$-closed sets in the interval $[\mathcal{A} \cup \mathcal{H}_2^{\oplus K_2}, G_1]$. Clearly, we have $\mathcal{H} = \mathcal{H}_1 \cup \mathcal{H}_2^{\oplus K_2} \subseteq \mathcal{A} \cup \mathcal{H}_2^{\oplus K_2}$, hence these $\varpi$-closed sets are all above $\mathcal{H}$. □

5.3. The lower part of the jungle. The lower part of the jungle, i.e., the interval $[\emptyset, \mathcal{A}] = \text{Sub}(\mathcal{A})$, seems to be more complicated than the upper part. We only prove here the analogue of Theorem 5.15: every nonempty $\varpi$-closed subset of $G_1$ has a continuum of $\varpi$-closed subsets. This implies immediately the promised result that $\emptyset$ has no upper covers in $\text{Sub}(G_1)$, or, equivalently, $\langle K_2 \oplus L \rangle_\varpi$ has no upper covers in $\text{Sub}(G)$. The proof of this result relies on the following construction of “blowing up” a graph by replacing its vertices by complete graphs. For an arbitrary graph $G$ and natural number $\ell$, let $G^\ell$ denote the graph defined by

$$V(G^\ell) = V(G) \times \{1, \ldots, \ell\} = \{(v, i) : v \in V(G), i \in \{1, \ldots, \ell\}\};$$

$$E(G^\ell) = \{(v, i), (v', i') : vv' \in E(V) \text{ or } v = v' \text{ and } i \neq i'\}.$$ 

(This is a special case of the so-called strong product of graphs, namely $G^\ell = G \boxtimes K_\ell$.)

Lemma 5.16. For every $G \in G_1$ and $\ell \geq 2$, we have $G^\ell \in \langle K_2 \rangle_\varpi$.

Proof. If $uv$ is an edge in $G$, then $\{u, v\} \times \{1, \ldots, \ell\}$ is a clique of size $2\ell$ in $G^\ell$, and these cliques cover every edge of $G^\ell$. Therefore, by Lemma 3.4, $G^\ell \in \langle K_2 \rangle_\varpi$, which is actually more than what we had to prove. □
Lemma 5.17. If \( n > m \geq 5 \) are odd numbers, then \( C_m^\ell \not\to C_n^\ell \).

Proof. As mentioned in the proof of Lemma 5.16, every edge of an arbitrary graph \( G \) gives rise to a clique of size \( 2\ell \) in \( G^\ell \). Moreover, if \( G \) contains no triangles (cliques of size 3), then these are the only cliques of size \( 2\ell \) in \( G \). Therefore, a homomorphism \( \varphi : G^\ell \to H^\ell \) for triangle-free graphs \( G \) and \( H \) induces a mapping \( \psi : E(G) \to E(H) \) such that if two edges \( e_1, e_2 \in E(G) \) have a common endpoint, then \( \psi(e_1) \) and \( \psi(e_2) \) also have a common endpoint.

Now let us assume that \( \varphi : C_m^\ell \to C_n^\ell \) is a homomorphism for some \( n > m > 3 \). Since \( C_n \) and \( C_m \) are triangle-free, we can consider the corresponding map \( \psi : E(C_m) \to E(C_n) \). Let \( e_1, \ldots, e_m \) be the edges of \( C_m \) in the cyclical order. Then \( \psi(e_1), \ldots, \psi(e_m) \) determine a connected subgraph with at most \( m \) edges in \( C_n \). Since \( n > m \), there is a vertex \( v \in V(C_n) \) that does not belong to this subgraph. Then \( \varphi(C_m) \) is disjoint from \( \{v\} \times \{1, \ldots, \ell\} \subseteq V(C_n^\ell) \), hence \( \varphi \) maps \( C_m^\ell \) into \( P_n^\ell \), where \( P_n \) is the path of length \( n \) obtained from \( C_n \) by removing the vertex \( v \). Clearly, \( P_n \to K_2 \), and \( P_n^{\ell-1} \to K_{2\ell} \). Thus we have \( C_m^\ell \to P_n^{\ell-1} \to K_{2\ell} \), which implies that \( \chi(C_m^\ell) \leq 2\ell \). However, it is easy to see that \( C_m^\ell \) is not \( 2\ell \)-colorable. (Actually, by a result of Stahl \([22]\), \( \chi(C_{2k+1}^\ell) = 2\ell+1+\lfloor \frac{\ell-1}{k} \rfloor \).) This contradiction shows that \( C_m^\ell \not\to C_n^\ell \).

\[ \square \]

Lemma 5.18. If \( n \geq 4 \) and \( m \geq 3 \), then \( K_m^\ell \not\to C_n^\ell \).

Proof. If \( n \geq 4 \) then \( C_n \) contains no triangles, and then the largest cliques in \( C_n^\ell \) are the cliques of size \( 2\ell \) (cf. the proofs of Lemma 5.16 and Lemma 5.17). If \( m \geq 3 \) then the size of \( K_m = K_m^\ell \) is \( m\ell > 2\ell \), hence \( K_m^\ell \not\to C_n^\ell \).

\[ \square \]

Lemma 5.19. Let \( N = \{5, 7, 9, \ldots\} \) and let \( T_n = K_n^\ell \oplus C_n^\ell \). Then for every \( n \in N \), we have \( T_n \not\in \langle \{T_m : m \in N, m \neq n\} \rangle_\mathcal{G} \).

Proof. Assume that \( T_n \in \langle \{T_m : m \in N, m \neq n\} \rangle_\mathcal{G} \) for some odd integer \( n \geq 5 \). By Lemma 3.3, there exist \( m_1, \ldots, m_k \in N \setminus \{n\} \) such that there is a complete homomorphism \( \varphi : T_{m_1} \oplus \cdots \oplus T_{m_k} \to T_n \). If \( m_i > n \) then \( T_{m_i} \not\to T_n \), as \( T_{m_i} \) has a clique of size \( m_i \ell \), whereas the largest clique in \( T_n \) is of size \( n\ell \). Therefore, we have \( m_i < n \) for \( i = 1, \ldots, k \). By Lemma 5.17 and Lemma 5.18, \( C_{m_i}^\ell \not\to C_n^\ell \) and \( K_{m_i}^\ell \not\to C_n^\ell \), hence \( \varphi \) maps \( T_{m_i} \) into \( K_{m_i}^\ell \) for each \( i \). However, this contradicts the surjectivity of \( \varphi \).

\[ \square \]

Lemma 5.20. For every \( G \in \mathcal{G}_1 \) and \( n \geq 3 \) we have \( K_n \in \langle G \rangle_\mathcal{G} \) if and only if \( \chi(G) \leq n \).

Proof. If \( K_n \in \langle G \rangle_\mathcal{G} \), then, by Lemma 3.3, there exists a complete homomorphism \( \varphi : k \cdot G \to K_n \) for some \( k \geq 1 \). Restricting \( \varphi \) to any one of the \( k \) copies of \( G \), we get a homomorphism (not necessarily complete) \( G \to K_n \), and this shows that \( \chi(G) \leq n \).

Now assume that \( \chi(G) \leq n \), and let us use the numbers \( 1, 2, \ldots, n \) for the \( n \) colors in proper \( n \)-colorings of \( G \). Let us fix an edge \( uv \in E(G) \), and for each pair of colors \( i \neq j \) let us choose a proper \( n \)-coloring of \( G \) such that \( u \) and \( v \) receive the colors \( i \) and \( j \), respectively. Joining all these \( \binom{n}{2} \) colorings we obtain a homomorphism \( \binom{n}{2} \cdot G \to K_n \), which is complete, as each edge \( ij \in E(K_n) \) is the image of one of the \( \binom{n}{2} \) copies of the edge \( uv \). This proves that \( K_n \in \langle G \rangle_\mathcal{G} \).

\[ \square \]

Theorem 5.21. For every \( \mathcal{G}_\exists \)-closed set \( \mathcal{H} \supseteq \emptyset \), the interval \( [0, \mathcal{H}] \) has continuum cardinality.

Proof. Let \( H \) be an arbitrary element of \( \mathcal{H} \), and let \( \ell = \chi(H) \). According to Lemma 5.20, we have \( K_\ell \in \langle H \rangle_\mathcal{G}_\exists \subseteq \mathcal{H} \). By Lemma 5.19, the map \( S \mapsto \langle \{T_m : m \in S\} \rangle_\mathcal{G}_\exists \) embeds the power set of \( N \) into \( \text{Sub } \langle \mathcal{G}_1 \rangle \). Moreover, \( \langle \{T_m : m \in S\} \rangle_\mathcal{G}_\exists \subseteq \mathcal{H} \) for every \( S \subseteq N \), since, by Lemma 5.16, \( T_n \in \langle K_\ell \rangle_\mathcal{G}_\exists \subseteq \mathcal{H} \) for all \( n \in N \).
