1. Introduction

Despite no European directive exists for soil protection, this key component of ecosystem needs to be protected. To fill the lack of tools to monitor the soil threats and to assess the impact of soil management, biological indicators have been developed in the French program Bioindicators 2 (ADEME) and a website allowing selection of relevant bioindicators depending on the question asked achieved. On the 47 plots of 13 sites (agricultural, industrial and forest), the influence of soil characteristics and soil use on the response of 80 biological parameters (fauna, flora and microorganisms) have been assessed by using linear multivariate regressions.

2. Materials and methods

In order to identify the parameters influencing the responses of bioindicators, multiple linear regressions were developed as (Eq 1)

\[ \log(Y + 1) = \log(A + 1) + \log(B + 1) + \ldots + z \]

where \( Y \) is the response of the bioindicator, \( A, B, \ldots \) represent the characteristics of the soil (physicochemical measurements and use, Table 1).

Table 1: Biological and physico-chemical parameters used for the multiple linear regressions
All combinations of the 18 available soil parameters were tested. Only models having a maximum of five independent variables and a ΔAICc <2 (Akaike criterion) were selected to choose a model from this selection, the indicator officials had a choice of three methods: (i) by default the selected model corresponded to the first model with the lowest number of explanatory variables (parcimony), (ii) the selected model corresponded to the model with the largest number of soil characteristics (explanatory variable) correlated to biological variable (response variable), (iii) if none of the above methods was selected, then the model chosen was based on the expertise of the scientist who have developed the indicator, identifying the most appropriate regression.

3. Results and discussion

3.1. Influence of soil parameters on the biological responses

The multiple linear regressions highlighted the influence of pool of soil parameters on the response of the bioindicators. By focusing on the occurrences of the parameters in equations, a clear influence of the soil texture (% clay, silt) and the rate of Corg is observed. Contaminants (metallic or organic) are also present in most equations. These strong influences of soil contaminants coupled to the soil parameters emphasize the need measure their bioavailability instead of total contents.

3.2. Implementation of web site devoted to the bioindicators

Following requests from potential users of bioindicators, a web site has been created (Fig 1). In this interface is listed all Bioindicators 2 program information. Another request was to have access to the program results. Thus, a component of the interface has been dedicated to the presentation of indicator results. Thus, users have access to “benchmarks” and can compare these values with the data generated on their own site. To allow users to select the bioindicator which best fits their site problematic, a screening tool has been developed based on scientific and technical (cost, standardization of the indicator, ease of implementation and ease of interpretation) criteria. With these criteria a scoring assigning a score to each tool for each of the four criteria has been achieved. The user can choose his site problematic, the type of indicator that wishes to use (indicator of accumulation, effect ...) and prioritize the four criteria. Then, user can have access to a set of detailed information on the selected bioindicator.

4. Conclusions

For the first time, the soil properties influence on the response of 80 bioindicators was characterized under similar environmental conditions. As each bioindicator is influenced by a specific pool of soil parameter, chemical measures cannot be used as a surrogate of biological measures. This program has provided usable tools for a biologically-based site management. The operational structures to implement bioindicators coupled with the web site will simplify the use of bioindication by end-users.
