HAL is a multi-disciplinary open access archive for the deposit and dissemination of scientific research documents, whether they are published or not. The documents may come from teaching and research institutions in France or abroad, or from public or private research centers.

L’archive ouverte pluridisciplinaire HAL, est destinée au dépôt et à la diffusion de documents scientifiques de niveau recherche, publiés ou non, émanant des établissements d’enseignement et de recherche français ou étrangers, des laboratoires publics ou privés.
Honeybee Conservation centers in Western Europe: an innovative strategy using sustainable beekeeping to reduce honeybee decline

Like most species, the «natural» genetic structure of the honeybee is the result of complex alternating evolutionary processes such as population history and demography, putative isolation of groups of populations during glacial events, genetic drift, natural migration and re-colonization processes, but also adaptation to local environments under Darwiniian selection. As a result of these interacting processes, studies have showed that honeybee biodiversity can be subdivided into at least 26 subspecies which are geographically structured into four evolutionary lineages, covering Africa, Europe and Western Asia. The western European lineage (M-lineage), which ranges from southern Iberia to Scandinavia and from the Atlantic coast to the Ural mountains, is the oldest lineage which colonized northern Europe about 1 million years ago. The M-lineage is composed of two honeybee subspecies: (i) the Iberian honeybee, *Apis mellifera iberiensis*, and (ii) the black honeybee, *A. m. mellifera*.

For about 20 years, the European honeybee has been subjected to a constant decline for which pesticides and pathogens seem to be the main contributors. However, recent surveys suggest that current honeybee declines in European apiaries can be also caused by commercial and European trade of honeybees by (i) the introduction of unadapted and artificially maintained colonies, and (ii) the spread of allochtone and invasive pathogens carried by allochtoive honeybees. Large molecular surveys have already been performed in France (Fig. 1A), in Spain and Portugal (Fig. 1B) to characterize the French, Spanish and Portuguese livestock of honeybees, and to assess the impact of imports of foreign queens. In France, high levels of introgression were measured in north-east and southwest. In these areas, the situation is worrying for the M lineage, especially for the native subspecies (the black honeybee), which genetic integrity is seriously threatened by C-lineage introgression (Fig. 1A).

Which solution?
Sustainable or intensive beekeeping practices?

Environmental stresses (e.g., malnutrition, exposure to agrochemicals, and apicultural mismanagement, urbanization, climate change, habitat loss)

Parasitism

Genetic diversity and vitality

Endangered honeybee lineages (focus on the M lineage, assumption: lower genetic diversity)

Setting up of honeybee conservation centers in Western Europe: an innovative strategy using sustainable beekeeping

The main goal of BEEHOPE, our BioDIVERSA ERANET funded project, is to set up, according to a North/South gradient, genetic conservatories of native honeybee populations. BEEHOPE is divided into four work packages (WP): (i) impact study on the genetic background (heritage) of our colonies; (ii) choice of our sites and establishment of preservation centers; (iii) monitoring of eco-ethological and physiological parameters of a honeybee colony, and spatio-temporal monitoring of pathogens and predators (e.g.: small hive beetle); (iv) dynamic interactions with stakeholders involved in the beekeeping sector for the development of a sustainable beekeeping (Fig. 2).

This European network of honeybee preservation centers (∼530,93 km² per preservation center) will have as missions: (i) to characterize the genetic and eco-ethological diversity of honeybees from the Western European lineage (M-lineage); (ii) to protect the genetic diversity of those populations; (iii) to constitute a reserve of diversity usable by the honeybee industry and beekeepers; (iv) to study the impact of the domesticated honeybee in the maintenance of local floristic diversity; and (v) to be able to use the honeybee as a bio-collector and as a biological indicator of environmental quality.
