Abstract. The pressure-volume-temperature equations of state have been constructed by combining experimental data and semiempirical estimations for a number of compounds recently synthesized under extreme pressure-temperature conditions. The solids with various bonding types were considered: covalent hard and superhard boron-rich and diamond-like compounds (e.g. B₆O, B₁₃N₂, BP, c-BC₅, and nano-cBN), ionic semiconductors (e.g. Mg₂C and Mg₂C₃), as well as intercalation compounds (e.g. clathrates Na₄Si₂₄ and Na₂₄⁺ₓSi₁₃₆), and simple substances (e.g. boron allotropes γ-B₂₈ [15–17], pseudo-cubic t’-B₅₂ [18]) and boron-rich compounds (boron subnitride B₁₃N₂ [19, 20]), as well as intercalation compounds (e.g. clathrates Na₄Si₂₄ and Na₂₄⁺ₓSi₁₃₆), and simple substances (e.g. boron allotropes γ-B₂₈ [15–17], pseudo-cubic t’-B₅₂ [18]). We also showed how the reliable p-V-T equations of state may be constructed using different types of data available.

1. Introduction

Recently high pressure–high temperature (HPHT) large-volume synthesis allowed obtaining a number of novel materials [1] for new challenging applications as superhard [2–6], advanced electronic [7], photovoltaic [8] and thermoelectric [9, 10] materials, as well as superconductors [11, 12]: (i) boron allotropes [13, 14] (orthorhombic γ-B₂₈ [15–17], pseudo-cubic t’-B₅₂ [18]) and boron-rich compounds (boron subnitride B₁₃N₂ [19, 20]), (ii) superhard compounds with diamond structure (nanostructured cBN [21], non-stoichiometric c-BC₅ [22, 23]); (iii) covalent clathrates of new stoichiometries (Na₄₋ₓSi₂₄ [8, 9] and Na₂₄₊ₓSi₁₃₆ [9, 10]) and even (iv) new unexpected semiconductors, like antifluorite Mg₂C [24], dense Mg₂C₃ [25] and pure silicon allotrope with quasi-direct bandgap, Si₂₄ [8].

For understanding of phase transformations and chemical interactions in the corresponding systems, one needs to explore the thermodynamics under HPHT conditions. And, although a part of the lacking data can be replaced by fitted parameters of common models [26–28] or with ab initio calculations [29], the reliable p-V-T equations of state (EOS) data are crucial for that. In the present paper we describe the method of construction of such equations of state using integrated form of the Anderson-Grüneisen equation [30, 31]. The method is efficient even in the case of small number of experimental data [32] and may be easily combined with ab initio, semiempirical and even empirical modeling.
2. Theoretical background
In our previous works [32, 33] we have shown that the Anderson-Grüneisen equation [30, 31], which takes into account the pressure dependence of thermal expansion through the volume change, i.e.
\[ \alpha(p, T) = \alpha(0, T) \left[ \frac{V(p, T)}{V(0, T)} \right]^\delta_T, \] (1)
can be integrated (under the assumption that $\delta_T$ is constant) to
\[ V(p, T) = V(0, T)^{-\delta_T} + V(p, 300)^{-\delta_T} - V(0, 300)^{-\delta_T} \] (2)
where thermal expansion (i.e. $V(0, T)$ at 0.1 MPa) and isothermal compression (i.e. $V(p, 300)$ at 300 K) can be presented in any analytical form, e.g. polynomial
\[ V(0, T) = V_0(1 + a(T - 300) + b(T - 300)^2), \] (3)
and Vinet equation of state [34]
\[ p(V, 300) = 3B_0 \left( \frac{V}{V_0} \right)^{-2/3} \left[ 1 - \left( \frac{V}{V_0} \right)^{1/3} \right] e^{1.5(B'_0 - 1)[1 - (V/V_0)^{1/3}].} \] (4)
Finally, the set of parameters needed to describe an EOS in the form (2) is $V_0 = V(0, 300) = M/\rho_0$, $B_0$, $B'_0$, $a$, $b$ and $\delta_T$ (usually between 4 and 6). And the Gibbs potential can be calculated as
\[ G(p, T) = G(0, T) + \int_0^p V(\pi, T) d\pi \]
\[ = G(0, T) + \int_0^p \left[ V(0, T)^{-\delta_T} + V(\pi, 300)^{-\delta_T} - V(0, 300)^{-\delta_T} \right]^{-1/\delta_T} d\pi. \] (5)

Such form of the EOS (2) allows one easily approximate the $V(p, T)$ in the vicinity of a new compound formation, which is often the principal domain of interest in the terms of HPHT thermodynamics. Here the unit cell volume can be estimated in situ using x-ray diffraction (300-K EOS may be measured on decompression).

In some other cases, the knowledge of phase equilibrium curves may allow evaluating the HPHT EOS of unknown phase through the known one. For example, we succeeded to fit the experimental melting curves ($p$-$T$ coordinates) of $\alpha$- and $\beta$-B$_2$O$_3$ and to find the parameters determining the $p$-$V$-$T$ EOS for liquid B$_2$O$_3$ (the results will be published elsewhere). The melting was observed experimentally, while the bulk modulus and thermal expansion parameters were adjusted so that the experimental curve fits the theoretical one.

3. EOS data and discussion
Table 1 shows the $p$-$V$-$T$ EOS data available from the experiment or estimated using various models (marked with an asterix in the table) for boron and boron-rich, diamond-like, Mg-C and Na-Si compounds.

In the case of boron-rich solids the only unknown bulk modulus, that of pseudo-cubic $t'$-B$_{52}$ phase was estimated using the density data by the method described elsewhere for various elastic characteristics of covalent and ionic materials [35–38] and previously justified for boron allotropes [39]. At the same time, the thermal expansion parameters are known just for B$_6$O [40, 41]. For both dense allotropes, $\gamma$-B$_{38}$ and $t'$-B$_{52}$, we propose to take, in the first approximation, values of $\beta$-B$_{106}$ [42], while for boron subnitride B$_{13}$N$_2$ one can take a value
of suboxide B₂O having similar crystal structure. Except for B₂O, the \( \delta_T \) parameter—linking 300-K \( p-V \) data with 0.1-MPa thermal expansion data—was fixed to 5.5. Figure 1 shows that the parameters well agree with experimental \textit{in situ} observations for B₁₃N₂. Better fit may be obtained with \( \delta_T = B'_0 = 4 \) (just like in the case of B₂O, \( \delta_T = B'_0 = 6 \)) or by adjusting the \( a \) and \( b \) thermal expansion parameters, or even by suggestion of a pressure drop from 5 to 4 GPa. So, the lack of experimental data does not allow making a choice, and so far we suggest a value of \( \delta_T = 5.5 \).

For diamond-like phases (nano-cBN, c-BC₅ and BP), as well as for Mg-C compounds, all bulk moduli were established experimentally. Only for BP the thermal expansion data at 0.1 MPa have been available in literature. In the case of Mg₂C the \( a \) and \( b \) parameters were established by fitting the \( p-V \) data at high temperature (around 1500 K) [29], while in other cases they were estimated from the literature data (for nano-cBN—its conventional counterpart [46], for c-BC₅—the linear combination of diamond [51] and boron [42]). \( \delta_T \) parameter was chosen as 5.5 for all compounds except Mg₂C. Figure 2 shows that the parameters well agree with experimental \textit{in situ} observations for c-BC₅. Just like in the case of B₁₃N₂ discussed above, the “ideal” match of an experimental point to the theoretical curve may be achieved, but it is not clear which parameter should be used for such adjustment (e.g. \( a \) or pressure drop during the

Table 1. \( p-V-T \) equation of state data for compounds synthesized at high pressure. Units: \( \rho \) in g/cm³; \( B_0 \) in GPa; \( B'_0 \) is dimensionless; \( a \) in 10⁶ K⁻¹; \( b \) in 10⁶ K⁻²; \( \delta_T \) is dimensionless.
In the case of clathrate compounds of the Na-Si system the situation with the data is the most complicated. High-temperature data, especially, at low pressure can hardly be obtained, since the compounds easily decompose. From another side, at high pressure these compounds often have only narrow domains of stability. However, it has been established that elastic properties mainly depend on the rigid silicon framework and are close to those of diamond silicon [52, 53].
For Na_{24+x}Si_{136} and Na_{4}Si_{24} the values of bulk moduli were fixed to that of Na_{24}Si_{136}, while for open framework “high-pressure” clathrate silicon, to the values of Si_{136} \[53,54\]. The experimental results on these compounds will be published elsewhere.

4. Conclusion

Finally, we have proposed a set of parameters that allow one to construct \( p-V-T \) equations of state for a number of newly discovered high-pressure solids. The reported data give a first approximation of the parameters for the construction of high-pressure phase diagrams with participation of boron for new advanced materials, as well as for the Mg-C and Na-Si systems, promising for production of unique semiconductive diamonds \[55\] and advanced silicon for optoelectronic applications \[8\].

Acknowledgments

The EOS measurements using \textit{in situ} x-ray diffraction were performed at ID06 & ID27 beamlines at the European Synchrotron Radiation Facility (Grenoble, France) and at F2.1 & P02.2 beamlines at HASYLAB-DESY (Hamburg, Germany). We are grateful to W. Crichton, J. Guignard, M. Mezouar, C. Lathe and Z. Konopková for providing assistance in using these beamlines. This work was financially supported by the Agence Nationale de la Recherche (grant ANR-2011-BS08-018).
