ABSTRACT: Many anticancer compounds are strong inhibitors of thioredoxin reductases (TrxRs), selenoenzymes involved in cellular redox regulation. This study examined the effect of two hydroxyferrocifens (**1**, FcOH; **2**, FcOHTAM) and of their corresponding quinone methides (QMs), **1-QM**, and **2-QM**, on these enzymes. In vitro, both QMs were more

potent TrxR inhibitors ($IC_{50} \approx 2.5 \mu M$) than the hydroxyferrocifens ($IC_{50} \approx 15 \mu M$). This inhibition was due to a Michael addition of the penultimate selenocysteine residue of TrxRs to the QMs. In Jurkat cancer cells, both **2** and **2-QM** inhibited TrxRs in the same proportion, leading to accumulation of oxidized forms of thioredoxin, while **1** and **1-QM** were scarcely effective. This difference of behavior was ascribed to the competitive conversion of **1-QM** to an inactive indene in protic medium. This set of experiments confirms for the first time the role played by ferrocenyl quinone methides on several biological targets and gives a molecular basis for these effects. It also highlights differences in the mechanisms of action of **1** and **2** in cancer cells.

INTRODUCTION

Triple negative breast cancers, melanomas, glioblastomas, pancreatic cancers, ovarian, and nonsmall-cell lung cancers are some of the cancers associated with the worst outcomes thanks to their ability to resist most of the standard therapies. The health challenge represented by these cancers can only be met by innovative medical approaches that combine ground-breaking chemistry with novel biology and the latest tools of medical intervention. All these cancers share the characteristics of intrinsic resistance to pro-apoptotic stimuli, which limits the effectiveness of the available chemotherapies.¹

In the search for new therapeutic strategies, a new medicinal chemistry based on the unique behavior of organometallic complexes of transition metals may provide a breakthrough. The approach is distinct from coordination chemistry²⁻⁴ because it concerns organometallics with a direct metal-carbon covalent bond, often associated with a low degree of oxidation. The advent of organometallic frameworks designed with precise biological end points in mind was delayed for some time by organometallic chemists' primary focus on catalysis, which for some years had the effect of relegating other aspects of the field to obscurity.⁵ This situation changed with the arrival of bioorganometallics.^{6,7} It is now clear that an innovative organometallic medicinal chemistry^{8,9} is supported by the distinctive properties of organometallic complexes, for example, the three-dimensional space-filling capability demonstrated by Dörr and Meggers for kinase and other enzyme inhibitors.¹⁰ Alternatively, some organometallic complexes inhibit target proteins by metal coordination to their active site.¹¹⁻¹³ In this context, the potential interest of *N*-heterocyclic carbene (NHC)

complexes of Au(I) and Ru(II) as anticancer drugs has been evaluated.¹⁴⁻¹⁷ NHC ligands stabilize metal ions against precipitation into aggregates under physiological conditions and at the same time can serve to deliver bioactive metal ions to the cellular targets. These species have mechanisms of action different from that of cisplatin² because redox proteins such as thioredoxin reductase (TrxR) can be considered as key targets.

Another strategy to overcome cancer cell resistance with new types of organometallic prodrugs is to use non-noble metals and generate active metabolites in the vicinity of redox targets. Among the usable organometallic complexes, the iron complexes occupy a privileged position owing to the abundance of this metal in the body and the particular nature of ferrocene, which is a compact and stable aromatic metallocene with redox properties and a bioisostere of benzene.⁸

For example, substitution of a phenyl ring by a ferrocenyl unit in OHTAM, the active metabolite of tamoxifen, the drug classically used to treat hormone dependent breast cancer leads to FcOHTAM (Chart 1), which showed a strong cytotoxic effect on both estrogen receptor positive and negative breast cancer cell lines (MCF-7 and MDA-MB-231, respectively).¹⁸⁻²⁰

Chart 1. Chemical Structures of the Ferrocenyl Derivatives under Study

Indeed an IC₅₀ of 0.5 μ M was found for the lipophilic complexes **2**, the corresponding diphenol analogue **3**, and 1.1 μ M for the ferrocenyl monophenol compound **1** on MDA-MB-231 cells.²¹⁻²³ Compound **3** and other ferrocifens were active against a large panel of cancer cell lines²⁴ but not on healthy cells (astrocytes, melanocytes).^{25,26} The effectiveness

of **2** and **3** delivered via lipid nanocapsules (LNC) has been studied in vivo on 9L-glioma models^{26,27} and on xenografted MDA-MB-231 cells.²⁸ A significant slowing of tumor progression was observed, demonstrating the antiproliferative activity of these compounds in vivo.

1, **2**, and **3** can undergo chemical oxidation to give the quinone methides (QM) as products of the initial oxidation of the Fe(II) of ferrocenyl to the Fe(III) of ferricinium.²⁹ Electrochemical experiments have provided elucidation of the oxidation pathway leading to the quinone methide, which occurs at biologically relevant potentials.³⁰ It has been speculated that the cytotoxicity of **1** and some other ferrociphenols may arise at least partly from the electrophilic character of the quinone methide metabolites.³¹

Two major systems, namely the thioredoxin (Trx) and glutathione (GSH) systems, are involved in the control of cellular thiol redox balance. The first system depends on thioredoxin reductase (TrxR) which is reduced by NADPH and in turn maintains Trx in the reduced form.^{32,33} Among other functions, Trx acts as an electron donor for the family of peroxiredoxins that catalyze the reduction of H₂O₂ to water.³⁴ TrxRs are large homodimeric flavoproteins, and two isoforms, a cytosolic (TrxR1) and a mitochondrial (TrxR2) form, have been identified.^{35,36} TrxRs possess an N-terminal redox center characterized by a dithiol motif (Cys-XXXX-Cys) and a C-terminal active site with a Cys-Sec motif (Sec = selenocysteine). The Sec residue is characterized by a low pK_a (5.24 for the selenol/selenate couple compared to 8.25 for the thiol/thiolate couple), resulting in an enhanced nucleophilic character.^{37,38} Thioredoxin reductase is considered an attractive target for development of anticancer agents as it is frequently overexpressed in cancer cells.³⁹⁻⁴¹ Some metal complexes inhibit TrxR at the nanomolar to submicromolar level mostly by metal coordination,⁴²⁻⁴⁴ while electrophilic organic compounds inhibit TrxR at the micro/submicromolar level.⁴⁵⁻⁵⁰ Both classes of inhibitors target TrxR via an (ir)reversible reaction with the Cys-Sec motif at the C-terminus.

The second system is based on glutathione, maintained in a reduced state by glutathione reductase (GR), which is in turn reduced by NADPH.^{51,52} Reduced glutathione acts as a substrate of glutathione peroxidase (GPx), another selenoenzyme able to decompose hydrogen peroxide to water,⁵³ thereby contributing, together with peroxiredoxins, to the maintenance of cell redox balance.

In the present study, the effect of **1** and **2** and their respective quinone methides (**1-QM**, **2-QM**) on the activity of the isolated selenoenzymes TrxR and GPx and the homologous enzyme GR as well as the reactivity of the QMs on organic models was investigated and compared. The effects of these compounds on molecules involved in cellular redox homeostasis was further studied on Jurkat cancer cells in order to shed light on the molecular mechanism of action of these compounds that may be responsible for cancer cell growth inhibition.

RESULTS

Synthesis of Quinone Methides (QMs). QMs derived from **1**, **2**, and **3** were synthesized by chemical oxidation in acetonitrile or acetone with freshly prepared Ag₂O following an improved protocol, allowing the compounds to be obtained in the solid form (Scheme 1). 2D NMR analysis showed that only the E isomers were obtained.²⁹

Scheme 1. Synthesis of the Quinone Methides

The QM of **3** (**3-QM**) proved to be quite unstable because it started to decompose before oxidation was complete. This is due to the presence of two oxidizable phenol groups on the molecule, possibly leading to uncontrollable overoxidation. The two other QMs showed reasonable stability, at least 4 weeks in the solid state when kept at -20 °C, and were thus chosen for this study. However, their stability in solution was limited (see below). Thus, although in vitro biochemical studies can be performed on both isolated enzymes and in

cancer cells (Jurkat cell line) with **1-QM** and **2-QM**, 1 mM stock solutions have to be freshly prepared for each set of experiments.

Figure 1. Concentration-dependent effects of the ferrocenyl compounds on the cytosolic (A) and mitochondrial (B) thioredoxin reductases, glutathione reductase (C), and glutathione peroxidase (D). In glutathione peroxidase activity determination (D), the concentration of the various compounds was 20 μM. Enzymatic activities were measured, after 30 min of incubation, as indicated in the Experimental Section.

Effects of Ferrocenyl Compounds on Isolated Enzymes (TrxR1, TrxR2, GR, and GPx). The inhibitory effect of the ferrocenyl derivatives on the enzymatic activity of purified TrxR1 (cytosolic isoform of thioredoxin reductase) was tested using the DTNB reduction method. As can be seen in Figure 1A, **1-QM** and **2-QM** were effective inhibitors of TrxR1, with IC_{50} values, after 30 min of preincubation with the enzyme, of 2.2 and 2.6 μM, respectively. Under the same experimental conditions, **1** and **2** were far less effective, exhibiting IC_{50} values of 14.4 and 15.0 μM, respectively, noticeably higher than those of the corresponding quinone methides. At shorter incubation times, **1-QM** gave a more rapid inhibitory effect than **2-QM** (not shown), however, this effect leveled off at 30 min incubation. The same compounds were also tested on the mitochondrial isoform of

thioredoxin reductase (TrxR2) which was still markedly inhibited by **1-QM** ($IC_{50} = 4.2 \mu M$), while **2-QM** displayed an IC_{50} value of $7.8 \mu M$ (Figure 1B). This difference of inhibitory efficiency between the two isoforms of TrxR may be due to the different properties of the mitochondrial and cytosolic enzymes (see Discussion).

The ferrocenyl derivatives were also tested as inhibitors of TrxR1 after their in situ oxidation with H_2O_2 /HRP (horseradish peroxidase). As shown in Supporting Information, Figure S1, both compounds **1** and **2** ($5 \mu M$) treated with H_2O_2 /HRP completely inhibited TrxR1 activity while H_2O_2 or HRP alone were ineffective. Compounds **1** and **2** treated with H_2O_2 /HRP showed UV-vis spectra consistent with those of the corresponding quinone methide derivatives obtained by chemical oxidation (Supporting Information, Figure S1).

Glutathione reductase, like thioredoxin reductase, belongs to the family of pyridine nucleotide oxidoreductases but lacks the thiol/selenol motif at the C-terminus. Interestingly, this enzyme was scarcely affected by any of the four compounds (Figure 1C) and a slight inhibition for some of them was observed only at relatively high concentrations.

Like thioredoxin reductase, glutathione peroxidase is also a selenoenzyme containing a selenocysteine in each subunit.⁵³ This enzyme is directly concerned with the removal of hydrogen peroxide using reducing equivalents of GSH. The phenols (**1**, **2**) and quinone methides (**QM-1**, **QM-2**) did not significantly alter the activity of glutathione peroxidase (Figure 1D). Similar selectivity for TrxR over GPx was previously observed in the case of alkylation-mediated inhibition by acylfulvenes.⁴⁸ Furthermore, to inhibit GPx, some gold complexes such as auranofin are required at relatively high concentrations in comparison to those needed for TrxR.⁵⁴ This inability of the quinone methides to inhibit GPx is probably linked to the fact that, unlike TrxR, the selenol active site is hidden within the enzyme core and consequently unable to interact with the bulky organometallic complexes.

Localization of the Ferrocenyl Compounds Inhibition Site on TrxR1. To obtain information on the type of inhibition exerted on thioredoxin reductase by the ferrocenyl derivatives, a BIAM (biotin-conjugated iodoacetamide) assay was used. This assay makes it possible to evaluate the ability of the compounds to react with the thiol/selenol motif. In fact, BIAM can selectively alkylate TrxR depending on pH. At pH 6.0, only selenocysteine and low pK_a cysteine can be alkylated, while at pH 8.5, both selenocysteine and cysteine can be derivatized by BIAM. As shown in Figure 2, preincubation of **2-QM** at $100 \mu M$ appeared to

Information, Figure S4), while the mixture of **1-QM** and reduced selenocystamine displayed two extra peaks at 6.7 and 14.3 min and almost complete disappearance of the 32.5 min peak (Supporting Information, Figure S5). Thus, for both QMs, only the selenol afforded addition products while the thiol was unreactive. ESI-MS analyses confirmed the formation of the Michael addition adducts only in the case of selenocystamine with peaks at m/z 633.4 and 532.2 for **2-QM** and **1-QM**, respectively (Supporting Information, Figures S7 and S9). Furthermore, competitive reaction of equimolar amounts of reduced cystamine and selenocystamine with both QMs led only to the formation of the selenide adducts (not shown). On the basis of HPLC analysis, the amount of selenide adduct **4**, formed from **2-QM**, was larger than that formed from **1-QM**. We interpret this finding as the highly favored competitive conversion of **1-QM** to the indene derivative **5** in protic medium (Scheme 2).⁵⁷ The indene adduct in the **1-QM** solution was identified as the major peak at $t_R = 31$ min by comparative analysis of an authentic sample. Comparatively, **2-QM** reproducibly appeared more stable in aqueous medium.

Scheme 2. (A) Reaction of Quinone Methide 2-QM with the selenol R_1SeH [$R_1 = (CH_2)_2NH_2$]; (B) Competitive Spontaneous Cyclization of 1-QM to Indene **5 in Protic Medium**

Effect of the Ferrocenyl Derivatives on Redox Enzyme Activity and on Glutathione Redox State in Tumor Cells. Thioredoxin reductase activity in Jurkat tumor cells was estimated by insulin reduction assay after treatment of cells with 10 or 20 μM ferrocenyl compounds for 24 h. As shown in Figure 3A, both **2** and **2-QM** induced a marked inhibition of TrxR activity in cell lysates.

Figure 3. Effects of ferrocenyl compounds on thioredoxin reductases (A), glutathione reductase (B), and glutathione peroxidase (C) in cell lysates. Jurkat cells were incubated for 24 h with 10 or 20 μ M compounds and lysed. Activities of the redox enzymes were estimated as reported in the Experimental Section.

Figure 4. Total (GSH + GSSG) and oxidized (GSSG) glutathione levels in Jurkat cells treated with ferrocenyl compounds. Cells (1×10^6) were treated with the indicated concentrations of ferrocenyl compounds for 24 h with refresh at 12 h. Cells were then collected and processed as indicated in the Experimental Section.

Under these experimental conditions, **2** and **2-QM** inhibited TrxR activity in a concentration-dependent fashion, with about 60% inhibition at 20 μ M. Conversely, the other two compounds (**1** and **1-QM**) were scarcely effective. Glutathione reductase and peroxidase were essentially not inhibited by ferrocenyl compounds. Rather, in the case of glutathione reductase, there was an increase of activity above the control especially in the presence of quinone methides (Figure 3B). Therefore, the total amounts of glutathione and of oxidized glutathione in cells incubated with the ferrocenyl compounds at 10 or 20 μ M were determined. As shown in Figure 4, an increase of total glutathione was observed for the

cells incubated with the quinone methides, except for the higher concentration of **2-QM**. The proportion of oxidized glutathione GSSG was also significantly increased in the presence of **2** and to a lesser extent in the presence of **1** (Figure 4).

Estimation of the Redox State of Cytosolic and Mitochondrial Thioredoxin in Jurkat Cells after Treatment with the Ferrocenyl Derivatives. The thioredoxin redox system consists of NADPH, thioredoxin reductase, and thioredoxin. The latter, in turn, delivers electrons to several proteins including peroxiredoxins involved in the control of hydrogen peroxide levels. Therefore, inhibition of thioredoxin reductase interrupts the electron flow along the system and may lead to accumulation of the oxidized forms of thioredoxin.

Figure 5. Redox state of cytosolic (A) and mitochondrial (B) thioredoxin of Jurkat cells treated with ferrocenyl compounds. Jurkat cells (2×10^6) in RPMI medium were incubated with the indicated concentrations of ferrocenyl compounds for 24 h with refresh after 12 h. Lysates were treated with 8 M urea in the presence of 30 mM iodoacetic acid and processed as described in the Experimental Section.

As shown in Figure 5A, the redox condition of cytosolic thioredoxin (Trx1) of Jurkat cells treated with the ferrocenyl compounds (10 or 20 µM) was evaluated by Western blot analysis. The potential oxidation states of Trx have been extensively analyzed and discussed.^{58,59} Both **2** and **2-QM** showed a marked effect on Trx1, as several oxidized and overoxidized states of this protein were clearly observed on the gel. The top band represents the most oxidized form of Trx1, which is particularly abundant in lanes b, c, and g.

1 and **1-QM** were far less effective in comparison to the corresponding **2** derivatives. Similarly, and consistently with the previous results, Trx2 was also markedly oxidized in the

presence of both **2** and **2-QM**, while a lower proportion of oxidized forms of Trx2 (but significantly higher than control) was observed for cells incubated with **1** and **1-QM** (Figure 5B).

DISCUSSION

Table 1 gives a full overview of the main biochemical results obtained with the ferrocenyl compounds on isolated enzymes and Jurkat cells.

Because quinone methides are reactive species with well-established electrophilicity, it was hypothesized that they could behave as inhibitors of TrxR. Indeed, both QMs under study exhibited an IC₅₀ around 2 μ M for the cytosolic form of TrxR while their phenol precursors were much less active on both TrxR1 and TrxR2. Subtle differences between **2-QM** and **1-QM** were observed on TrxR2, as the former was only half as active as the latter. Even though TrxR1 and TrxR2 share common structural features, they have recently been shown to display subtle differences in substrate selectivity and inhibition by gold compounds.⁶⁰ Other differences might be taken into account to explain the selectivity of **2-QM** toward TrxR1 such as the more basic character of TrxR2 with respect to TrxR1⁶¹ and the much higher sensitivity of TrxR1 to calcium ion inhibition with respect to TrxR2.⁶²

Further experiments using the BIAM assay suggested that the selenol group of Sec498 was the target of both QMs. Accordingly, the structurally related enzyme glutathione reductase, which contains two Cys residues instead of the C-terminal Cys-Sec motif, was not affected by any of the ferrocenyl compounds. The other important selenoenzyme glutathione peroxidase was also not affected by any of the ferrocenyl compounds, indicating that an accessible selenocysteine residue was required for reaction with the QMs. Model reactions carried out between both QMs and reduced cystamine and selenocystamine confirmed that selective alkylation of selenol occurred at neutral pH as evidenced by ESI-MS analyses. In contrast, the QMs derived from OHTAM and metabolite E (which is the phenyl analogue of **1**) undergo fast reaction with GSH at physiological pH (half-life of 4 min).^{55,56} This discrepancy is attributable to the lower electrophilic character of the ferrocenyl quinone methides because of the delocalization of positive charge onto the ferrocenyl substituent, which leads to marked selectivity between thiols and selenols.

Table 1. Summary of the Biological Effects Observed in Vitro or in Jurkat Cancer Cells in the Presence of the Ferrocenyl Compounds 1 and 2 and Their Corresponding QMs

	1	2	1-QM	2-QM
	In Vitro Tests			
IC ₅₀ values on TrxR1 (μM) ^a	14.4 ± 1.8	15.0 ± 1.1	2.6 ± 0.7	2.2 ± 0.5

^aCytosolic isoform of thioredoxin reductase. ^bMitochondrial isoform of thioredoxin reductase. ^cAt 50 μM. ^dAt 20 μM. ^eMeasured by alkylation of TrxR1 with BIAM after incubation with 100 μM of the compounds. ^fNot done. ^gCells first incubated with the compounds, then Trx activity measured on lysates. ^hControl = 5%. ⁱObserved at both 10 and 20 μM. ^jObserved only at 20 μM.

The effect of the ferrocenyl complexes on the activity of the same enzymes and the redox state of Trx and GSH was subsequently examined in Jurkat tumor cells. Both **2** and the corresponding QM strongly inhibited total TrxR activity in cell lysates, indicating not only

that **2** was able to cross the cell membrane, but more importantly, that it underwent oxidation to its quinone methide, which is a much more efficient inhibitor of TrxR. Almost no inhibition of TrxR was observed with **1** or its QM in Jurkat cells. This difference of behavior between the two complexes may be related to the inability of **1** to convert to its QM in cancer cells and/or to the higher chemical stability of **2-QM** with respect to **1-QM**. Indeed, **1-QM** was found to rapidly undergo a cyclization reaction affording an indene devoid of Michael acceptor reactivity.⁵⁷

Similarly to the isolated enzymes, the activity of glutathione reductase and peroxidase in cell lysates was not altered. On the contrary, stimulation of glutathione reductase activity was observed, particularly with **1-QM**. Therefore, the effect of the ferrocenyl compounds on the glutathione level and its redox state was examined. It was found that together with GR, the total glutathione content increased, especially upon incubation with the QMs. The increased expression of GR and GSH points to the fact that QMs might stimulate some signaling pathways such as the Keap1-Nrf2 system involved in the regulation of expression of cytoprotective genes. This pathway is well-known to be induced by ROS and electrophiles of both natural and synthetic origins, including Michael acceptors, in a process leading to the expression of genes encoding a broad range of antioxidant enzymes such as peroxidases and enzymes involved in glutathione synthesis.⁶³ Compared to the control, the relative proportion of oxidized glutathione was five and three times higher in cells incubated with **2** and **1**, respectively. Because no inhibition of glutathione reductase was simultaneously observed, the high level of GSSG most probably resulted from oxidative stress. This is in full agreement with the high level of ROS detected in MDA-MB-231 breast cancer cells upon incubation of **2** and **1** (Supporting Information, Figure S10).^{64,65}

On the other hand, accumulation of oxidized forms of cytosolic and mitochondrial thioredoxins upon incubation with both **2** and its QM correlated well with the inhibition of cellular TrxR by both molecules. According to Du et al., these oxidized forms might be active in redox signaling.⁵⁹ These results again corroborate the fact that **2** is able to enter cells and undergoes oxidation to the QM form which appears as the active molecule able to inhibit TrxR and restrict the electron flow toward Trx, therefore stimulating its oxidation. Hence the putative mechanism of action of **2** that also rationalizes its cytotoxicity, appears to originate from its intracellular oxidation to the QM. This metabolite acts as an inhibitor of thioredoxin reductase, resulting in the accumulation of oxidized forms of thioredoxin which may in turn

transmit its oxidized conditions to various cellular targets. Compound **1** and its QM appeared to behave differently in that they had scarcely any effect on the redox state of Trx1, which again correlates with the previous finding that neither **1** nor **1-QM** significantly inhibited TrxR in Jurkat cells (see above). However, **1** and its QM induced some oxidation of the mitochondrial form of Trx. This selectivity of **1** toward Trx2 may arise from the higher sensitivity of Trx2 to oxidative stress.⁶⁶ On the whole, the two ferrocifens under study displayed a similar behavior on isolated enzymes but not in cancer cells.

CONCLUSION

In conclusion, several pieces of biochemical evidence suggesting that the cytotoxicity of **2** originates from its intracellular conversion to an electrophilic quinone methide derivative, first hypothesized in 2006,⁶⁷ are provided herein for the first time. Thanks to the presence of the ferrocenyl substituent on **2**, the QM was sufficiently stable to enable selective alkylation of TrxR both as isolated enzyme and in Jurkat cells. This study also underscored that **1** behaved differently owing to the very short lifetime of its QM in physiological medium that precluded TrxR inhibition in cancer cells. Nevertheless, this study substantiates the unique role of the ferrocenyl entity in the anticancer activity of both **1** and **2** and shows that activation, at least in part, goes through an intracellular oxidation pathway.

EXPERIMENTAL SECTION

Synthesis. **1** and **2** were synthesized according to the literature.^{22,68} Other chemicals were purchased from various manufacturers and used as received.

General Remarks. All reactions and manipulations were carried out under an argon atmosphere using standard Schlenk techniques. Acetonitrile was distilled over P₂O₅, acetone was dried over CaCl₂, diethyl ether was distilled over sodium/benzophenone, and pentane was dried over 4 Å molecular sieves prior to use. Ag₂O was prepared according to the literature procedure.⁶⁹ ¹H and ¹³C NMR spectra were acquired on a Bruker 300 MHz spectrometer. Mass spectrometry was carried out at the “Service de Spectrometrie de Masse” at ENSCP, Paris. Microanalyses were performed by the “Service de Microanalyse ICSN” at Gif sur Yvette, France. Elemental analysis and NMR were used to determine the purity of the compounds, and the purity of **1-QM** and **2-QM** was found to be higher than 96%.

p-[(Z)-1-Phenyl-2-ferrocenyl-2-butenylidene]benzenone, **1-QM**.

Compound **1** (0.204 g, 0.5 mmol) was dissolved in anhydrous acetonitrile (58 mL). Ag₂O (0.416 g, 1.8 mmol, 3 equiv) was added, and the mixture was stirred for 2 h at room temperature under argon (or nitrogen). The red solution of quinone methide formed was separated from solid by centrifugation and evaporated. A red oil (180 mg, 89% yield) of quinone methide was obtained. Then 3 mL of diethyl ether was added to dissolve the quinone methide. The solution was concentrated at about 1.5 mL, and then 5 mL of pentane were added to precipitate the quinone methide (red oil). The solution was discarded and the quinone methide **1-QM** was dried under vacuum. **1-QM** was finally isolated as a red solid (130 mg). ¹H NMR (300 MHz, acetone-*d*₆; Supporting Information, Figure S11) δ 1.67 (d, *J* = 7.1 Hz, 3H, CH₃), 3.96 (s, 5H, C₅H₅), 4.09 (broad s, 1H, C₅H₄), 4.11 (broad s, 1H, C₅H₄), 4.15 (broad s, 1H, C₅H₄), 4.26 (broad s, 1H, C₅H₄), 6.34–6.41 (m, 2H, C₆H₄), 6.42 (q, *J* = 7.1 Hz, 1H, CH=), 7.46–7.53 (m, 6H, C₆H₅+ C₆H₄), 7.61 (dd, *J* = 9.9 and 2.6 Hz, 1H, C₆H₄). ¹³C NMR (75.46 MHz, acetone-*d*₆; Supporting Information, Figure S12): δ = 15.9 (Me), 68.9 (2 CH, C₅H₄), 70.0 (7 CH, C₅H₄+ C₅H₅), 88.0 (C₅H₄, C_{ip}), 125.5 (CH), 129.4 (2 CH, C₆H₅), 129.5 (CH), 129.7 (CH), 130.7 (CH), 131.6 (2 CH, C₆H₅), 138.3 (CH), 138.9 (C), 139.1 (C), 139.7 (CH), 146.0 (C), 157.5 (C), 186.9 (CO). p-[(*Z*)-1-(*p*-Dimethylaminopropoxyphenyl)-2-ferrocenyl-2-butenylidene]benzenone, **2-QM**. Compound **2** (0.204 g, 0.4 mmol) was dissolved in dry acetone (10 mL). Ag₂O (0.277 g, 1.2 mmol) was added, and the mixture was stirred for 1 h at room temperature. The red solution of quinone methide formed was separated from the solid by centrifugation and evaporated. A red oil (180 mg, 88% yield) of quinone methide was obtained. Three mL of diethyl ether was added to dissolve the quinone methide. The solution was concentrated at about 1.5 mL, and then 5 mL of pentane were added to precipitate the quinone methide (red oil). The solution was discarded, and the quinone methide **2-QM** was dried under vacuum. **2-QM** was finally isolated as a red solid (120 mg). ¹H NMR (300 MHz, acetone-*d*₆; Supporting Information, Figure S14): 1.64 (d, *J* = 7.1 Hz, 3H, CH₃), 1.91 (m, 2H, CH₂), 2.15 (s, 6H, NMe₂), 2.39 (t, *J* = 6.8 Hz, 2H, CH₂), 3.97 (s, 5H, C₅H₅), 4.06 (broad s, 1H, C₅H₄), 4.10–4.15 (m, 2H + 2H, OCH₂ + C₅H₄), 4.26 (broad s, 1H, C₅H₄), 6.33–6.38 (m, 2H, C₆H₄), 6.41 (q, *J* = 7.1 Hz, 1H, CH=), 7.08 (d, *J* = 8.8 Hz, 2H, C₆H₄), 7.46 (d, *J* = 8.8 Hz, 2H, C₆H₄), 7.56 (q, *J* = 15.5 and 3.00 Hz, 1H, C₆H₄), 7.59 (q, *J* = 15.5 and 3.00 Hz, 1H,

C₆H₄). MS (CI; Supporting Information, Figure S15): $m/z = 508.34 [M + H]^+$. Anal. Calcd for C₃₁H₃₃FeNO₂: C, 73.37; H, 6.55; N, 2.76. Found: C, 73.34; H, 6.74; N, 2.65.

Estimation of Isolated Enzyme Activities. Highly purified cytosolic thioredoxin reductase (TrxR1) was prepared from rat liver according to the method of Luthman and Holmgren.³⁵ Mitochondrial thioredoxin reductase (TrxR2) was purified from isolated rat liver mitochondria following the procedure of Rigobello and Bindoli.⁷⁰

Thioredoxin reductases activity was determined by estimating the DTNB-reducing property of the enzymes in the presence of NADPH. Aliquots of highly purified TrxR1 (60 nM) or TrxR2 (60 nM) in 0.2 M Tris HCl buffer (pH 8.1), 1 mM EDTA, and 0.05 mM NADPH were preincubated for 30 min with the various compounds. Afterward, 0.2 mM NADPH was further added, and the reaction was initiated with 1 mM DTNB and monitored spectrophotometrically at 412 nm for about 10 min. Yeast glutathione reductase activity was measured in 0.2 M Tris-HCl buffer (pH 8.1), 1 mM EDTA, and 0.25 mM NADPH after 30 min of preincubation with the various compounds. The assay was initiated by addition of 1 mM GSSG and followed spectrophotometrically at 340 nm. Glutathione peroxidase activity was evaluated by adaptation of current assays.^{48,71} GPx from bovine erythrocytes (0.02 U) was incubated with 20 μ M ferrocenyl compounds in a total volume of 0.5 mL of 50 mM Hepes buffer (pH 7.0) containing 3 mM EDTA and 0.3 mM NADPH at 25 °C. After 30 min, 4 mM GSH and 25 nM yeast glutathione reductase were added. After 2 min of incubation, the reaction was started by the addition of 200 μ M *tert*-butyl hydroperoxide and followed at 340 nm by the decrease of NADPH absorption.

BIAM Assay. TrxR1 (1 μ M), prereduced in the presence of 60 μ M NADPH, was incubated with 3 μ L of freshly prepared 1 mM stock solution (100 μ M final concentration) of ferrocenyl compounds for 30 min at room temperature in 20 mM Tris-HCl buffer (pH 7.4) containing 200 μ M NADPH and 1 mM EDTA. After incubation, 8 μ L of the reaction mixture were removed and added to 50 μ M biotinylated iodoacetamide (BIAM) in either 0.1 M Tris-HCl at pH 8.5 or 0.1 M Hepes-Tris at pH 6.0. Samples were incubated at room temperature for additional 30 min to alkylate the remaining -SH groups of the enzyme.⁷² Then aliquots of BIAM-modified enzyme were loaded without reducing agent onto Bis-Tris Gel NUPAGE (12%) and transferred to a nitrocellulose membrane. Proteins labeled with BIAM were detected with horseradish peroxidase-conjugated streptavidin and enhanced chemiluminescence detection.

Reaction of the Quinone Methides with Thiol and Selenol.

The disulfide cystamine and the diselenide selenocystamine were treated with 2 equiv TCEP (tris(2-carboxyethyl)phosphine) in triethanolamine buffer pH 6.8 to reduce them into the corresponding thiol/selenol. After a few minutes, the quinone methides in solution in MeCN were added (final concentration 1 mM, 0.1 equiv with respect to thiol/selenol). The final reaction mixtures contained 50% MeCN. The reaction outcomes were monitored by RP-HPLC with UV detection on a 150 mm × 2 mm Nucleodur Gravity C18 column 5 μm (Macherey-Nagel). Species were eluted using a gradient from 10 to 80% MeCN–0.1% TFA in H₂O–0.1% TFA in 30 min (for **2-QM**) or a gradient from 40 to 90% MeCN–0.1% TFA in H₂O–0.1% TFA in 25 min (for **1-QM**) at 0.25 mL/min. After several hours, the mixtures were analyzed by ESI-MS.

Determination of Thioredoxin Reductases, Glutathione Reductase, and Glutathione Peroxidase in Cell Lysates. Jurkat cells were grown at 37 °C in 5% carbon dioxide atmosphere using RPMI 1640 medium containing 10% fetal calf serum and supplemented with 2 mM L-glutamine.

Jurkat cells (2×10^6) were incubated with 10–20 μM compounds for 24 h with refresh after 12 h. After incubation, cells were harvested and washed with PBS. Each sample was lysed with a modified RIPA buffer: 150 mM NaCl, 50 mM Tris-HCl, 1 mM EDTA, 0.1% SDS, 0.5% DOC, 1 mM NaF, and an antiprotease cocktail (“Complete” Roche, Mannheim, Germany) containing 0.1 mM PMSF. After 40 min of incubation at 0 °C, lysates were centrifuged at 14000g for 5 min. The supernatants were tested for enzyme activities. Aliquots of lysates were subjected to thioredoxin reductase determination with the insulin reduction test.⁷³ Briefly, 12 μg proteins of cell lysates were incubated for 40 min in a final volume of 50 μL in 100 mM Hepes buffer (pH 7.6) and in the presence of 15 mM EDTA, 1.5 mM NADPH, 0.25 mM insulin, and 100 μM Trx from *Escherichia coli*. The reaction was stopped by addition of 0.2 mL of 1 mM DTNB in 0.2 M Tris-HCl buffer (pH 8.1) containing 1 mM EDTA and 7.2 M guanidine, and samples were estimated at 412 nm.

Glutathione reductase activity was measured at 25 °C on 80 μg protein/mL as reported above. Glutathione peroxidase activity was determined in 400 μg protein/mL of lysate in a final volume of 0.25 mL of 0.2 M Tris-HCl buffer (pH 8.1) and 1 mM EDTA as described above.

Glutathione Redox State Estimation in Cell Lysates. First, 1×10^6 Jurkat cells in complete medium were incubated for 24 h with refresh at 12 h. Then cells were collected, washed twice with cold PBS, and then lysed and deproteinized with 6% *meta*-phosphoric acid. After 10 min at 4 °C, samples were centrifuged and supernatants were neutralized with 15% Na_3PO_4 and assayed for total glutathione.⁷⁴ Sample aliquots were derivatized with 2-vinylpyridine⁷⁵ in order to block reduced glutathione, and oxidized glutathione was then estimated. Protein concentration was determined by the Lowry et al. assay⁷⁶ in deproteinized samples washed with 1 mL of ice-cold acetone, centrifuged at 11000g, dried, and then dissolved in 62.5 mM Tris/HCl buffer (pH 8.1) containing 1% SDS.

Redox Western Blot Analysis of Trx1 and Trx2. The redox state of Trx was detected using a modified Western blot analysis.^{58,77} Briefly, to determine the redox state of thioredoxin, after cell treatment with 10 or 20 μM ferrocenyl compounds for 24 h with refresh after 12 h, 2×10^6 Jurkat cells after two washings with PBS were lysed in 150 μL of urea lysis buffer (100 mM Tris-HCl, pH 8.3) containing 1 mM EDTA, 8 M urea, and 30 mM IAA in order to alkylate free thiols. Incubation was carried out at 37 °C for 30 min. After centrifugation, the cell lysates were precipitated by ice-cold acetone–1 N HCl (98:2). The precipitate was washed twice with ice-cold acetone–1 N HCl– H_2O (98:2:10) and resuspended in 70 μL of urea lysis buffer including 3.5 mM DTT and incubated for 30 min at 37 °C. Afterward, 3.5 μL of 200 mM IAM were added to the various samples, followed by incubation for 15 min at 37 °C. Protein concentration was determined by the Lowry assay.⁷⁶ Proteins were separated by urea-PAGE gel (7% acrylamide/bis(acrylamide) in 8 M urea) and blotted using Turbo System (Bio-Rad Laboratories, Hercules, CA, USA). Membranes were probed with the primary antibodies respectively for Trx1 (FL 105) and for Trx2 (H75) (Santa Cruz Biotechnology, Santa Cruz, CA, USA).

Statistical Analysis. All the values are the mean $\pm$ SD of not less than five measurements. Multiple comparisons were made by one-way analysis of variance followed by the Tukey–Kramer multiple comparison test.
