Abstract

The quantitative verification of Probabilistic Automata (PA) is undecidable in general. Unary PA are a simpler model where the choice of action is fixed. Still, the quantitative verification problem is open and known to be as hard as Skolem’s problem, a problem on linear recurrence sequences, whose decidability is open for at least 40 years. In this paper, we approach this problem by studying the languages generated by unary PAs (as defined below), whose regularity would entail the decidability of quantitative verification.

Given an initial distribution, we represent the trajectory of a unary PA over time as an infinite word over a finite alphabet, where the \( n \)\textsuperscript{th} letter represents a probability range after \( n \) steps. We extend this to a language of trajectories (a set of words), one trajectory for each initial distribution from a (possibly infinite) set. We show that if the eigenvalues of the transition matrix associated with the unary PA are all distinct positive real numbers, then the language is effectively regular. Further, we show that this result is at the boundary of regularity, as non-regular languages can be generated when the restrictions are even slightly relaxed. The regular representation of the language allows us to reason about more general properties, e.g., robustness of a regular property in a neighbourhood around a given distribution.

1 Introduction

Markov decision processes (MDPs for short) are a standard model for describing probabilistic systems with nondeterminism. The system or controller has a strategy according to which it chooses an action at every step, which is then performed according to a probability distribution defined over the set of possible resultant states. The usual question is whether some property (e.g. reaching a set of \textit{Goal} states) can be achieved with probability at least some threshold \( \gamma \).

In many interesting settings, the controller cannot observe the state in which it operates or only has partial information regarding the state (Partially Observable MDPs, POMDPs). Probabilistic automata (PAs for short) \cite{20,19} form the subclass of POMDPs where the controller cannot observe anything. The problem of whether there is a strategy to reach \textit{Goal} with probability at least a threshold \( \gamma \) (also called a cut-point) is already undecidable \cite{4}. Even approximating this probability has been shown undecidable in PAs \cite{12}. In fact, deciding whether there exists a sequence of strategies with probability arbitrarily close to \( \gamma = 1 \) is already undecidable \cite{8}, and only very restricted subclasses are known to ensure decidability \cite{7,6}.

A line of work, which we follow, is to consider unary PAs \cite{5,21}, where the alphabet has a single letter. That is, there is a unique strategy, and the model is essentially a Markov chain. Surprisingly, the ‘simple’ problem of whether there exists a finite number of steps after which the probability to be in \textit{Goal} is higher than the threshold \( \gamma \in (0,1) \) is open and has recently been shown \cite{3} to be as hard as the so-called \textit{Skolem’s problem}, which is a

Table 1 A summary of the results in this paper.

long-standing open problem on linear recurrence sequences [13, 11, 15]. One way to tackle the problem is to approximate it, asking whether for all \( \epsilon \) there exists a number of steps \( n_\epsilon \) after which the probability to be in \( \text{Goal} \) is at least \( \gamma - \epsilon \). The decidability and precise complexity of this problem has been explored in [5]. A more general approximation scheme, valid for much more general questions which can be expressed in some LTL logic, has also been tackled by generating a regular language of approximated behaviors [1].

In this paper, we study classes for which the language of exact behaviors is \((\omega-)\)regular, allowing for the exact resolution of any regular question (e. g. checking any LTL formula [1, 2]). We define the trajectory from a given initial distribution as an (infinite) word over the alphabet \{A,B\}. The \( n \)th letter of a trajectory being A (for Above, respectively, B for Below) represents that after \( n \) steps the probability to be in \( \text{Goal} \) is greater than or equal to (respectively lesser than) the threshold \( \gamma \). Further, we consider the language of a unary PA as the set of trajectories (words) ranging over a (possibly infinite) set of initial distributions. Thus, we can answer questions such as: does there exist a trajectory from the set of initial distributions satisfying a regular property or do all trajectories satisfy it. We can also tackle more complicated questions such as robustness wrt. a given initial distribution \( \delta_{\text{init}} \): does a regular property hold for all initial distributions “around” \( \delta_{\text{init}} \).

As motivation, consider a population of yeast under osmotic stress [14]. The stress level of the population can be studied through a protein which can be marked (by a chemical reagent). For the sake of illustration, consider the following simplistic model of a Markov Chain \( M_{\text{yeast}} \) with the protein being in 3 different discrete states (namely the concentration of the protein being high (state 1), medium (state 2) and low (state 3)). The transition matrix, also denoted \( M_{\text{yeast}} \), gives the proportion of yeast moving from one protein concentration level to another one, in one time step (say, 15 seconds).

\[
M_{\text{yeast}} = \begin{pmatrix}
0.8 & 0.1 & 0.1 \\
0.1 & 0.8 & 0.1 \\
0.2 & 0.1 & 0.7
\end{pmatrix}
\]

For instance, 20% of the yeast with high protein concentration will have low protein concentration at the next time step. The marker can be observed optically when the concentration of the protein is high. We know that the original proportion of yeast in state 1 is \( 1/3 \) (by counting the marked yeast population), but we are unsure of the mix between low and medium. The initial set of distributions is thus \( \text{Init}_{\text{yeast}} = \{(1/3,x,2/3-x) \mid 0 \leq x \leq 2/3\} \). The language of \( M_{\text{yeast}} \) will tell us how the population evolves wrt the number of marked yeast being above or below the threshold \( \gamma_{\text{yeast}} = 5/12 \), depending on the initial distribution in \( \text{Init}_{\text{yeast}} \). Now, suppose an experiment with yeasts reveals that there are at first less than \( 5/12 \) of marked yeast (i.e. with high concentration of proteins), then more than \( 5/12 \) of marked yeast, and eventually less than \( 5/12 \) of marked yeasts. That is, the trajectory is B for a while, then A for a while, then it stabilises at B. Let us call this property as \( (P_{\text{yeast}}) \) (note that this is a regular property). We are interested in checking whether our simplistic model exhibits at least one trajectory with the property \( (P_{\text{yeast}}) \), and if yes, the range of initial values generating trajectories with this property.

Our contributions as depicted in table 1 are the following: if the eigenvalues of the
transition (row-stochastic) matrix associated with the unary PA are distinct roots of real numbers, then any trajectory from a given initial distribution is ultimately periodic. This is tight, in the sense that, there are examples of trajectories which are not ultimately periodic even for unary PAs with 3 states [2, 21] (with some eigenvalue not root of any real number).

Our main result is that if, further, the eigenvalues are distinct positive real numbers, then the language generated by a unary PA starting from a convex polytope of initial distributions is effectively regular. Surprisingly, this result is also tight: there exist unary PA with eigenvalues being distinct roots of real numbers (starting from a convex initial set) which generate a non-regular language, as we show in Section 6.

The proof of our main regularity result is surprisingly hard to obtain. First, for each trajectory $\rho$, one obtains easily a number of steps $n_\rho$ after which the trajectory is constant. However, there is in general no bound on $n_\rho$ uniform over all $\rho$ in the language. Thus, while every trajectory is simple to describe, the language turns out to be in general much more complex. We prove that the language does have a representation as a finite union of languages of the form $w_1 A^1 B^1 A^2 B^2 A^3 \cdots B^m A^m$ with a bounded number of alternations. Our method computes effectively the language of $M_{\text{yeast}}$, as $M_{\text{yeast}}$ has positive real eigenvalues, answering the question whether there exists an initial trajectory s.t. property ($P_{\text{yeast}}$) holds.

2 Preliminaries and definitions

Definition 1. A Probabilistic Automaton (PA) $\mathcal{A}$ is a tuple $(Q, \Sigma, (M_\sigma)_{\sigma \in \Sigma}, \text{Goal})$, where $Q$ is a finite set of states, $\Sigma$ is a finite alphabet, $\text{Goal} \subseteq Q$, and $M_\sigma$ is the $|Q| \times |Q|$ transition stochastic matrix for each letter $\sigma \in \Sigma$. The PA is called unary PA (uPA for short) if $|\Sigma| = 1$.

For a unary PA $\mathcal{A}$ on alphabet $\{\sigma\}$, there is a unique transition matrix $M = M_\sigma$ of $Q \times Q$ with value in $[0, 1]$. For all $x \in Q$, we have $\sum_{y \in Q} M(x, y) = 1$. In other words, $M$ is the Markov chain on set of states $Q$ associated with $\mathcal{A}$.

A distribution $\delta$ over $Q$ is a function $\delta : Q \to [0, 1]$ such that $\sum_{q \in Q} \delta(q) = 1$. Given $M$ associated with a uPA, we denote by $M\delta$ the distribution given by $(M\delta)(q) = \sum_{q' \in Q} \delta(q')M(q', q)$ for all $q \in Q$. Notice that, considering $\delta$ and $M\delta$ as row-vectors, this corresponds to performing the matrix multiplication. That is, we consider $M$ as a transformer of probabilities, as in [10, 1]: $(M\delta)(q)$ represents exactly the probability to be in $q$ after applying $M$ once, knowing that the initial distribution is $\delta$. Inductively, $(M^n\delta)(q)$ represents the probability to be in $q$ after applying $n$ times $M$, knowing that the initial distribution is $\delta$. We now review literature relating several problems on uPA with the Skolem’s problem, named after the Skolem-Mahler-Lech Theorem [11],[13].

2.1 Relation with the Skolem problem

We start by defining three basic problems which have been studied extensively in different contexts. Given an initial distribution $\delta_0$ and a uPA $\mathcal{A}$ with Matrix $M$, target states $\text{Goal}$ and threshold $\gamma$:

Existence problem: does there exist $n \in \mathbb{N}$ such that the probability to be in $\text{Goal}$ after $n$ iterations of $M$ from $\delta_0$ is $\gamma$ (i.e., $\sum_{q \in \text{Goal}} (M^n\delta_0)(q) = \gamma$)?

Positivity problem: for all $n \in \mathbb{N}$ is the probability to be in $\text{Goal}$ after $n$ iterations of $M$ from $\delta_0$ at least $\gamma$ (i.e., $\sum_{q \in \text{Goal}} (M^n\delta_0)(q) \geq \gamma$)?

Ultimate Positivity problem: does there exist $n \in \mathbb{N}$ s.t., for all $m \geq n$, the probability to be in $\text{Goal}$ after $m$ iterations of $M$ from $\delta_0$ is at least $\gamma$ (i.e., $\sum_{q \in \text{Goal}} (M^m\delta_0)(q) \geq \gamma$)?
Note that all these problems are defined from a fix initial distribution $\delta_0$. These problems for PAs are specific instances of problems over general recurrence sequences, that have been extensively studied [15, 9]. It turns out that the existence for the special PA case is as hard as the existence (Skolem) problem over general recurrence sequences as shown in [3].

**Theorem 1.** [3, 9] For general unary PAs, the existence and positivity are as hard as the Skolem’s problem.

The positivity result comes from the interreducibility of Skolem’s problem and the positivity problem for general recurrence sequences [9]. The decidability of Skolem has been open for 40 years, and it has been shown that solving positivity, ultimate positivity or existence for general uPAs even for a small number of states (<50, depending on the problem considered) would entail major breakthroughs in diophantine approximations [17].

### 2.2 Simple unary PAs

In order to obtain decidability, we will consider restrictions over the matrix $M$ associated with the uPA. The first restriction, fairly standard, is that $M$ has distinct eigenvalues, which makes $M$ diagonalizable.

**Definition 2.** A stochastic matrix is *simple* if all its eigenvalues are distinct. A uPA is *simple* if its associated transition matrix is.

Some decidability results [18, 16] have been proved in the case of distinct eigenvalues for variants of the Skolem, which implies the following for *simple* uPAs:

**Theorem 2.** For simple unary PAs, ultimate positivity is decidable [18].

For simple unary PAs with at most 10 states\(^1\), positivity is decidable [16].

We will consider the *simple* uPA restriction. Notice that the decidability restrictions in Theorem 2 for these two closely related problems have led to two different papers [16],[18] in the same conference, using different techniques. As we want to answer in a uniform way any regular question (subsuming among others the above three problems and regular properties such as $(\gamma_{\text{yeast}})$) for uPAs of all sizes, we will later impose more restrictions. We start with the simple well-known observation that a simple unary PA has a unique stationary distribution.

**Lemma 1.** Let $M$ be a simple stochastic matrix. Then there exists a unique distribution $\delta_{\text{stat}}$ such that $M\delta_{\text{stat}} = \delta_{\text{stat}}$.

**Proof.** We give a sketch of proof here. We will later get an analytical explanation of this result. We have $M\delta = \delta$ iff $(M-I\delta)\delta = 0$. As $M$ is diagonalizable and 1 is a eigenvalue of $M$ of multiplicity 1, we have $\text{Ker}(M-I\delta)$ is of dimension 1. The intersection of distributions and of $\text{Ker}(M-I\delta)$ is of dimension 0, that is, it is a single point. ▶

As usual with PAs, we consider the probability to be in the set of states $\text{Goal}$, that is $\sum_{q\in\text{Goal}}(M^n\delta)(q)$. We consider only one threshold $\gamma$, for simplicity. In fact, the case of multiple thresholds reduces to this case, since the behavior is non-trivial for only one threshold, namely $\gamma_{\text{stat}} = \sum_{q\in\text{Goal}}\delta_{\text{stat}}(q)$ (see Lemma 11 in the appendix).

---

\(^1\) One more than the Skolem variant because of the fact that all the rows of a Markov chain sum to 1
2.3 Trajectories and ultimate periodicity

We want to know whether the $n^{th}$ distribution $M^n \delta$ of the trajectory starting in distribution $\delta \in \text{Init}$ is above the hyperplane defined by $\sum_{q \in \text{Goal}} x_q = \gamma$, i.e., whether $\sum_{q \in \text{Goal}} [M^n \delta](q) \geq \gamma$. We will write $\rho_n(\delta) = A$ (Above) for $\sum_{q \in \text{Goal}} [M^n \delta](q) \geq \gamma$, and $\rho_n(\delta) = B$ (Below) else.

\begin{definition}
The trajectory $\rho_S = \rho_0 \rho_1 \cdots \in \{A, B\}^\omega$ from a distribution $\delta$ is the infinite word with $\rho_n = \rho_n(\delta)$ for all $n \in \mathbb{N}$.
\end{definition}

We write the eigenvalue of $M$ as $p_0, \ldots, p_k$ with $||p_i|| \geq ||p_j||$ for all $i < j$. Notice that $k + 1 = |Q|$ the number of states (as the uPA is simple). It is a standard result that all eigenvalues of Markov chains have modulus at most 1, and at least one eigenvalue is 1. We fix $p_0 = 1$. As shown in Lemma 12 in the appendix, we have, for some $a_i(\delta) \in \mathbb{C}$:

$$(1) \quad \rho_S(n) = A \iff \sum_{i=0}^{k} a_i(\delta)p_i^n \geq \gamma$$

In the following, we denote $u_k(n) = \sum_{i=0}^{k} a_i(\delta)p_i^n$ for all $n \in \mathbb{N}$, If $\rho_S$ is (effectively) ultimately periodic (i.e., of the form $uv^n$), every (omega) regular property, such as existence, positivity and ultimate positivity is decidable (and are in fact easy to check). Unfortunately, this is not always the case, even for small simple unary PAs.

\begin{theorem}
[2] There exists an initial distribution $\delta_0$ and simple unary PA $A$ with 3 states, and coefficients and threshold in $\mathbb{Q}$, such that $\rho_{\delta_0}$ is not ultimately periodic.
\end{theorem}

\begin{proof}[Proof Sketch] The unary PA is given by: $\text{Goal} = \{1\}$ is the first state, $\gamma = \frac{1}{3}$ and the associated matrix $M_0$ and initial distribution $\delta_0$ are:

$$M_0 = \begin{pmatrix} 0.6 & 0.1 & 0.3 \\ 0.3 & 0.6 & 0.1 \\ 0.1 & 0.3 & 0.6 \end{pmatrix} \quad \text{and} \quad \delta_0 = \begin{pmatrix} 1 \\ 1 \\ 2 \end{pmatrix}$$

The reason the trajectory is not ultimately periodic follows from the fact that the eigenvalues of $M_0$ are $1, r_0 e^{i\theta_0}$ and $r_0 e^{-i\theta_0}$ with $r_0 = \sqrt{19}/10$ and $\theta_0 = \cos^{-1}(4/\sqrt{19})$.
\end{proof}

An easy way to obtain ultimately periodic trajectories is to restrict to eigenvalues $v$ which are roots of real numbers, that is, there exists $n \in \mathbb{N} \setminus \{0\}$ with $v^n \in \mathbb{R}$.

\begin{proposition}
Let $A$ be a simple unary PA with eigenvalues $(p_i)_{i \leq m}$ all roots of real numbers. Then $\rho_S$ is ultimately periodic for all distributions $\delta$. The (ultimate) period of $\rho_S$ can be chosen as any $m \in \mathbb{N} \setminus \{0\}$ such that $p_i^m$ is a positive real number for all $i \leq m$.
\end{proposition}

Now, for a finite state (Büchi) automaton $B$ over the alphabet $\{A, B\}$, the membership problem, of whether a given single trajectory $\rho_S \in L(B)$, is decidable. As it is easy to obtain a (small) automaton $B$ for each of the existence, positivity and ultimate positivity problem such that this problem is true iff $\rho_S \in L(B)$, we obtain:

\begin{proposition}
Let $A$ be a simple unary PA with eigenvalues all roots of real numbers. Let $\delta_0$ be a distribution. Then the existence, positivity and ultimate positivity problems from initial distribution $\delta_0$ are decidable.
\end{proposition}
3 Language of a unary PA

Using automata-based methods allows us to consider more complex problems, where the initial distribution is not fixed. We define the set \( \text{Init} \) of initial distributions as a convex polytope, that is the convex hull of a finite number of distributions.

**Definition 4.** The language of a unary PA \( A \) wrt. the set of initial distributions \( \text{Init} \) is \( \mathcal{L}(\text{Init}, A) = \{ \rho_\delta \mid \delta \in \text{Init} \} \subseteq \{ A, B \}^* \).

Note that \( A \) and \( B \), and the language, depend on the threshold \( \gamma \). As we assumed this threshold value to be fixed, the language only depends on \( A \) and \( \text{Init} \). As \( A \) is often clear from the context, we will often write \( \mathcal{L}(\text{Init}) \) instead of \( \mathcal{L}(\text{Init}, A) \). For the yeast example \( M = M_{\text{yeast}} \), we have eigenvalues 1; 0.7; 0.6:

\[
M \cdot \begin{pmatrix} 5/12 \\ 1/3 \\ 1/4 \end{pmatrix} = 1 \begin{pmatrix} 5/12 \\ 1/3 \\ 1/4 \end{pmatrix} ; \quad M \cdot \begin{pmatrix} 5/12 \\ -5/12 \\ 0 \end{pmatrix} = 0.7 \begin{pmatrix} 5/12 \\ -5/12 \\ 0 \end{pmatrix} ; \quad M \cdot \begin{pmatrix} 5/12 \\ 0 \\ -5/12 \end{pmatrix} = 0.6 \begin{pmatrix} 5/12 \\ 0 \\ -5/12 \end{pmatrix}
\]

We can decompose two initial distributions \( \delta_1, \delta_2 \in \text{Init}_{\text{yeast}} \) on the eigenvector basis:

\[
\begin{pmatrix} 1/3 \\ 1/4 \\ 5/12 \end{pmatrix} = \frac{1}{5} \begin{pmatrix} 5/12 \\ -5/12 \\ 0 \end{pmatrix} - \frac{2}{5} \begin{pmatrix} 5/12 \\ 0 \\ -5/12 \end{pmatrix} ; \quad \begin{pmatrix} 1/3 \\ 1/3 \\ 1/4 \end{pmatrix} = \frac{1}{5} \begin{pmatrix} 5/12 \\ -5/12 \\ 0 \end{pmatrix} - \frac{1}{5} \begin{pmatrix} 5/12 \\ 0 \\ -5/12 \end{pmatrix}
\]

Projecting on the first component, we have \( \rho_{\delta_1}(n) = A \text{iff } \frac{1}{12} 0.7^n - \frac{1}{12} 0.6^n \geq 0 \), that is \( \rho_{\delta_1} = B^4 A^\omega \). Also, \( \rho_{\delta_2}(n) = A \text{iff } \frac{1}{12} 0.6^n \geq 0 \), that is \( \rho_{\delta_2} = B^\omega \). With the techniques developed in the following, we can prove more generally that, for all \( n \in \mathbb{N} \), we can find an \( \epsilon \) s.t., \( \delta = (1/3 \ 1/3 - \epsilon \ 1/3 + \epsilon)^T \) has trajectory \( \rho_\delta = B^n A^\omega \), and that \( \mathcal{L}(\text{Init}_{\text{yeast}}) = B^* A^\omega \cup B^\omega \). Thus, property (\( P_{\text{yeast}} \)), from Introduction, does not hold for every initial distribution.

In general, if \( \mathcal{L}(\text{Init}, A) \) is regular, then any regular question will be decidable. For instance, if \( \mathcal{L}(\text{Init}, A) \) is regular, then it is decidable whether there exists \( \delta_0 \in \text{Init} \) such that the existence problem is true for \( A, \delta_0 \). One can also ask whether for a given convex polytope \( Q \), some property (such as positivity) expressed e.g. with \( LTL\mathcal{L} \) [1] is true. Taking \( \delta \) in the interior of \( Q \), this corresponds to checking the robustness of the property around \( \delta \).

Clearly, simple PA \( A \) does not ensure the regularity of \( \mathcal{L}(\text{Init}, A) \) because of Theorem 3 (by choosing \( \text{Init} = \{ \delta_0 \} \) which is a convex polytope). Surprisingly, restricting eigenvalues to be distinct and roots of real numbers does not ensure regularity either (see Section 6). In the following, we thus take a stronger restriction: we assume that the eigenvalues of \( M \) are distinct and positive real numbers. That is, \( p_0 = 1 > p_1 > \cdots > p_k \geq 0 \) with \( k + 1 = |Q| \) the number of states. From Proposition 1, we obtain as corollary that for all \( \delta_0 \), we have either \( \rho_{\delta_0} = wA^\omega \) or \( \rho_{\delta_0} = wB^\omega \) for \( w \) a finite word of \( \{ A, B \}^* \):

**Corollary 2.** Let \( M \) be a stochastic matrix with positive real eigenvalues. Then every trajectory \( \rho_{\delta_0} \) is ultimately constant.

However, the language \( \mathcal{L}(\text{Init}_{\text{yeast}}, M_{\text{yeast}}) \) shows that \( \mathcal{L}(\text{Init}, A) \) is not always of the simple form \( \bigcup_{w \in W_A} wA^\omega \cup \bigcup_{w \in W_B} wB^\omega \), for \( W_A, W_B \) two finite sets of finite words over \( \{ A, B \}^* \). Nevertheless, in the next two sections, we succeed in proving the regularity of \( \mathcal{L}(\text{Init}, A) \), which is our main result:

**Theorem 4.** For all unary PA \( A \) with distinct positive real eigenvalues, and for a convex polytope \( \text{Init} \), the language \( \mathcal{L}(\text{Init}, A) \) is effectively regular.
Notice that the hypotheses of Theorem 4 are decidable for $A$ with rationals coefficients in $Q$. Indeed, it suffices to use linear algebra in order to compute the eigenvalues and vectors, and check whether their complex part is null. We also show that this result is tight, i.e., relaxing the hypothesis leads to non-regularity (see Section 6).

### 3.1 Partition of the set $\text{Init}$ of initial distributions

Recall that we write $u_i(n) := \sum_{i=0}^{k} a_i(\delta) p_i^{\delta}$, where $a_i(\delta)$ are given by Equation (1) from the previous section. Because the eigenvalues are real numbers, $a_i(\delta)$ is a real number for every $i$ and $\delta$. Notice that $a_i$ is a linear function in $\delta$, that is, $a_i(\alpha \delta_1 + \beta \delta_2) = \alpha a_i(\delta_1) + \beta a_i(\delta_2)$. The trajectory $p_\delta$ depends crucially on the sign of $a_0(\delta)$, and if $a_0(\delta) = 0$, on the sign of $a_1(\delta)$, etc. First, let $L_1 = \{ \delta \mid a_0(\delta) = \cdots = a_i(\delta) = 0 \}$. This is a vector space (i.e., it is in $\mathbb{R}^k$ and contains the space of distributions over $Q$), as for any $\nu_1, \nu_2 \in \mathbb{R}^k$, we have $\nu_1, \nu_2 \in L_i$ implies that any linear combination $\alpha \delta_1 + \beta \delta_2 \in L_i$ (since $a_i(\nu)$ is linear in $\nu$, the kernel of a linear function is a vector space).

We will divide the space of distributions into a finite set $\mathcal{H}$ of convex polytopes $H \in \mathcal{H}$ to keep the sign of each $a_i$ constant on each polytope. Each $H \in \mathcal{H}$ satisfies that for all $e, f \in H$, for all $i \leq k$, we have $a_i(e), a_i(f)$ do not have different signs (either one is $0$, or both are positive or both are negative). This can be done since $a_i(\nu)$ is continuous (as it is linear). This is pictorially represented in the left of figure 1. For instance, we divide $\text{Init}_{\text{S. Akshay, B. Genest, B. Karelovic, N. Vyas}}$ into three polytopes: $\{(1/3, y, 2/3 - y) \mid y \leq 1/3\}$ and $\{(1/3, y, 2/3 - y) \mid 1/3 \leq y \leq 5/12\}$ and $\{(1/3, y, 2/3 - x) \mid y \geq 5/12\}$ as for $\delta = (1/3, 1/3, 1/3)$ we have $a_0(\delta) = 1, a_1(\delta) = 0$ (and $a_2(\delta) = -1/5$) and for $\delta = (1/3, 5/12, 1/4)$ we have $a_0(\delta) = 1, a_1(\delta) = -1/5, a_2(\delta) = 0$.

In general, we can assume that each of $H \in \mathcal{H}$ is the convex hull of $k + 2$ points (else we divide further: this can be done as the space has dimension $k + 1$). Consider the right part of Figure 1. Let $\text{Init}$ be the convex hull of points $e, f, g, h$ (in three dimensions) and $a_0(x) = 0$ and $a_2(x) > 0$ for all $x \in \{e, f, g, h, t\}$. Hence the sign of each trajectory ultimately depends upon $a_1(x)$. In the example, $a_1(g) = a_1(h) = 0$ while $a_1(e) > 0 > a_1(f)$. Then there is a point $t$ between $e$ and $f$ for which $a_1(t) = 0$ (in fact, $t = |a_1(f)|/(|a_1(e)| + |a_1(f)|)e + |a_1(e)|/(|a_1(e)| + |a_1(f)|)f$). We have $L_1 \cap \text{Init}$ is the convex hull of $h, g, t$. We break $\text{Init}$ into two convex polytopes, the convex hull of $h, g, t, e$ and the convex hull of $h, g, t, f$.

Let $H \in \mathcal{H}$. We let $P$ be the finite set of (at most $k + 2$) extremities of $H$. In particular, $H$ is the convex hull of $P$. Now it suffices to show that the language $L(H)$ (taking $H$ as initial set of distributions) of each of these convex polytopes $H$ is regular to prove that the language $L(\text{Init}) = \bigcup_{H \in \mathcal{H}} L(H)$ is regular.
3.2 High level description of the proof

The proof of the regularity of the language $\mathcal{L}(H)$ starting from the convex polytope $H$ is performed as follows. We first prove that there exists a $N_{\max}$ such that the ultimate language (after $N_{\max}$ steps) of $H$ is effectively regular using analytical techniques.

**Definition 5.** Given $N_{\max}$, the **ultimate language** from a convex polytope $H$ is defined as $\mathcal{L}^{N_{\max}}_{\text{ult}}(H) = \{v \mid \exists w \in \{A, B\}^{N_{\max}}, wv \in \mathcal{L}(H)\}$.

In the next section (Corollary 6), we show that this ultimate language $\mathcal{L}^{N_{\max}}_{\text{ult}}(H)$ is regular, of the form $(A^*)B^* \cdots B^*A^* \cup (A^*)B^* \cdots A^*B^*$ with a bounded number of switches between $A$ and $B$'s. However, while for each prefix $w \in \{A, B\}^{N_{\max}}$, the set $H_w$ of initial distributions in $H$ whose trajectory starts with $w$ is a convex polytope; the language $\mathcal{L}(H_w)$ from $H_w$ can be complex to represent. It is not in general $w\mathcal{L}^{N_{\max}}_{\text{ult}}(H)$, but a strict subset.

In Section 5 (Lemma 9), we prove that the language $\mathcal{L}(H')$ associated with some carefully defined convex polytope $H' \subseteq H$ has a regular language, of the form $\bigcup_{w \in W} wA^*A^*B^* \cdots B^*A^* \cup wA^*A^*B^* \cdots A^*B^*$ for a finite set $W$. Further, removing $H'$ from $H$ gives rise to a finite number of convex polytopes with a smaller number of “sign-changes”, as formally defined in the next section. Hence we can apply the arguments inductively (requiring potentially to change the $N_{\max}$ considered). Finally, the union of these languages gives the desired regularity characterization for $\mathcal{L}(H)$.

4 Ultimate Language

4.1 Limited number of switches.

We first show that the ultimate language $\mathcal{L}^{N_{\max}}_{\text{ult}}(H)$ is included into $A^*B^*A^* \cdots A^*B^* \cup A^*B^*A^* \cdots B^*A^*$ for some $N_{\max} \in \mathbb{N}$, with a limited number of switches between $A$ and $B$ depending on properties of the set $P$ of extremities of $H$.

We start by considering the generalisation of a sequence $u_{\delta}$ to a function over positive reals, and we will abuse the notation $u_{\delta}$ to denote both the sequence and the real function.

**Definition 6.** A function of type $k \in \mathbb{N}$ is a function of the form $u : \mathbb{R}_{\geq 0} \to \mathbb{R}$, with $u(x) = \sum_{j=0}^{k} \alpha_j x^j$, where $\alpha_0 > \cdots > \alpha_k > 0$.

Now, let $u : \mathbb{R}_{\geq 0} \to \mathbb{R}$ be a continuous function. We can associate with function $u$ the (infinite) word $\omega(u) \in \{A, B\}^\omega$, $\omega(u) = (a_0a_1 \ldots)$, where for all $n \in \mathbb{N}$, $a_n$ is defined as $a_n = A$ if $u(n) \leq 0$ and $a_n = B$ otherwise. We have easily that $\rho_\delta = \omega(u_{\delta})$. Knowing the zeros of $u_{\delta}$ and its sign before and after the zeros, defines uniquely the trajectory $\rho_\delta$.

For example, let $u$ be such that it has four zeros: $u(N-0.04) = u(N+10.3) = u(N+20) = u(N+35) = 0$ for some integer $N$. Assume that $u(0) < 0, u(N+1) > 0, u(N+11) < 0, u(N+30) < 0$ and $u(N+40) > 0$. Thus, by continuity of $u$, $u$ is strictly negative on $[0, N-1]$, non negative on $[N, N+10]$, strictly negative on $[N+11, N+34]$ and non negative on $[N+35, \infty)$. Thus the associated trajectory $\rho_\delta = B^N A^{11} B^{24} A^2$.

Hence, it is important to analyze the zeros of functions $u_{\delta}$. If the number of zeros is bounded, then the number of alternations between $A$’s and $B$’s in any trajectory $\rho_\delta$ from $\delta \in H$ will be bounded. In fact, it is a standard result (which we do not use hence do not reprove here) that every type $k$ function $u$ has at most $k$ zeros. We now show a more precise bound on the number of zeros. Namely, for the convex hull $H'$ of a finite set $P'$ of distributions in $H$, the number of alternations between $A$’s and $B$’s in $H'$ is limited by the number of alternations of the sign of the dominant coefficients of the distributions in $P'$.
Let $z \in \mathbb{N}$. For $i \in \{0, \ldots, z\}$, let $u^i(x) := a_0^i p_0^x + a_1^i p_1^x + \cdots + a_k^i p_k^x$, with $p_0 > p_1 > p_2 > \cdots > p_k > 0$, representing for instance the functions associated with the $z+1$ extremities of $H'$. We denote $\text{dom}(u^i)$ the dominant coefficient of $u^i$, that is the smallest integer $j$ with $a_j^i \neq 0$. We reorder $(u^i)_i \in \{1, \ldots, z\}$ such that $\text{dom}(u^i) \leq \text{dom}(u^{i+1})$ for all $i < z$. We denote $\text{sign}_\text{dom}(u_i) \in \{+1, -1\}$ as the sign of $\text{dom}(u^i)$. We will assume, as for $H$, that for all $i,i', j, a_j^i$ and $a_j^{i'}$ have the same sign. We let $Z(u^0, \ldots, u^z) = \{|i \leq z - 1 | \text{sign}_\text{dom}(u^i) \neq \text{sign}_\text{dom}(u^{i+1})\}$. That is, $Z(u^0, \ldots, u^z)$ is the number of switches of sign between the dominant factors of $u^i$ and $u^{i+1}$. We have $0 \leq Z(u^0, \ldots, u^z) \leq z$. Notice that as for $\text{dom}(u^i) = \text{dom}(u^{i'})$, we have $\text{sign}_\text{dom}(u^i) = \text{sign}_\text{dom}(u^{i'})$, $Z(u^0, \ldots, u^z)$ does not depend upon the choice in the ordering of $(u^i_{i \in \{0, \ldots, z\}}$. We can now give a bound on the number of zeros of functions which are convex combinations of $u^0, \ldots, u^z$.

**Lemma 3.** Let $u^0, \ldots, u^z$ be $z + 1$ type $k$ functions. There exists a $N_{\text{nae}} \in \mathbb{N}$ such that for all $\lambda_i \in [0,1]$ with $\sum \lambda_i = 1$, denoting $u(x) = \sum_{i=0}^z \lambda_i u^i(x)$, $u(x)$ has at most $Z(u^0, \ldots, u^z)$ zeros after $N_{\text{nae}}$. Further, if $u(x)$ has exactly $Z(u^0, \ldots, u^z)$ zeros after $N_{\text{nae}}$, then its sign changes exactly $Z(u^0, \ldots, u^z)$ times (that is, no zero is a local maximum/minimum).

In other words, we show that $u(x)$ behaves like a polynomial of degree $Z(u^0, \ldots, u^z)$ (as it has $Z(u^0, \ldots, u^z)$ dominating factors), although it has degree $k > Z(u^0, \ldots, u^z)$. In fact, we prove that for $\ell = \text{dom}(u^i)$, the coefficients $a_j^i p_j$ for all $j > \ell$ play a negligible role wrt. $a_j^i p_j$.

Let $H \in \mathcal{H}$, and $P$ its finite set of extremal points. We can apply Lemma 3 to $u^0, \ldots, u^z$, the functions associated with the points of $P$ (in decreasing order of dominating coefficient), and obtain a $N_{\text{nae}}$. Now, since $P$ is finite, the trajectories from $P$ are ultimately constant, hence there exists $N_y$ such that for all $i \leq y$, the trajectory of $u^i$ is $wA^d$ or $wB^d$ for some $w \in \{A, B\}^{N_y}$. We define $N_H$ to be the maximum of $N_y$ and $N_{\text{nae}}$. With this bound on the number of zeros, we deduce the following inclusion for the ultimate language $L_\text{ult}^N(H)$:

**Corollary 4.** Let $y = Z(u^0, \ldots, u^z)$. The ultimate language $L_\text{ult}^N(H) \subseteq C_1^* \cdots C_{y-1}^* C_y^* \cup C_1^* \cdots C_{y-1}^* C_y^*$ for $\{C_i, C_{i+1}\} = \{A, B\}$ for all $i < y$; and $C_y = A$ iff $\text{sign}_\text{dom}(u^0)$ is positive.

We can have 4 different sequences for $C_1^* \cdots C_{y-1}^* C_y^*$ with $\{C_i, C_{i+1}\} = \{A, B\}$, depending on the first and last letters $C_1, C_y$ (or equivalently, $C_y$ and parity of $y$ which determines $C_1$).

The proof of our main result on regularity of $\mathcal{L}(H)$ will proceed by induction over the switching-dimension $Z(H)$ of $H$ which we define as $Z(H) = Z(u^0, \ldots, u^z)$. Notice that we could define the switching dimension for any convex set (not necessarily a polytope) whenever the sign of $a_{1}(\delta)$ does not change within the convex set. Finally, we also define $\text{sign}_\text{dom}(H) = \text{sign}_\text{dom}(u^0)$.

### 4.2 Characterization of the Ultimate Language.

We now show that the ultimate language of $H$ is exactly $L_\text{ult}^N(H) = A^* B^* A^* \cdots A^* B^* \cup A^* B^* A^* \cdots B^* A^*$, with at most $Z(H)$ switches of signs. We will state the associated technical Lemma 5 in the more general settings of “faces” as defined below, as it will be useful in the next section. Let $P$ be the finite set of extremal points of a $H$. We call $(f^0, \ldots, f^y) \subseteq P$ a face of $H$ if $Z(f^0, \ldots, f^y) = y = Z(H)$ for the functions $(f^0, \ldots, f^y)$ associated with the extremal points $(f^0, \ldots, f^y)$. Notice that denoting $H'$ the convex hull of $F$, we can choose $N_{H'} = N_H$ (which is not the case for $H'$ an arbitrary polytope included into $H$).

**Lemma 5.** Given a face $(f^0, \ldots, f^y) \subseteq P$ of $H$ with associated functions $v^i$, we have, for all $n_1, n_2, \ldots, n_y \in \mathbb{N}$ there exist $\lambda_i \in [0,1]$ with $\sum \lambda_i = 1$, such that denoting $\nu(x) = \sum_i \lambda_i v^i(x)$, $L(\nu) = wA^{n_1} B^{n_2} \cdots B^{n_y} A^n$ (for $y$ even) for some prefix $w \in \{A, B\}^{N_H}$. 

---
That is, for all $n_1, \ldots, n_y$, one can find a prefix $w$ of size $N_H$ and a point $\delta$ in the convex hull of $e^1, \ldots, e^y$, such that $p_\delta = w^{n_1}A^{n_2}\cdots A^{n_y}$ (assuming the correct parity of $y$). Let $H'$ be the convex hull of $f^0, \ldots, f^y$. Hence $Z(H') = Z(H)$. Then, the ultimate language of $H'$ (i.e., the language after prefixes of size $N_H$ associated with $y$) contains $A^*B^* \cdots B^*A^*$ with $y$ switches between $A$ and $B$, which is the converse of Corollary 4. We can thus deduce the following about the ultimate language:

\begin{quote}
\textbf{Corollary 6.} \(L_{\text{ult}}^H(N_H) = L_{\text{ult}}^H(H') = C_1^*C_2^* \cdots C_y^*A^\omega \cup C_1^*C_2^* \cdots C_{y-1}^*B^\omega\) with \(\{C_i, C_{i+1}\} = \{A, B\}\).
\end{quote}

\textbf{Proof.} We first prove the result for $L_{\text{ult}}^N(H')$. We can apply lemma 5 to $H'$ and lemma 3 to $H'$. We obtain the first part of the union. Now, let $H'' \subseteq H'$ be the convex hull of $e^1, \ldots, e^y$ (that is excluding $e^0$). Each point $\delta$ in $H' \setminus H''$ has a trajectory which ends with $A^\omega$, as $\text{dom}(u_{\delta}) = \text{dom}(v^1)$, and thus $\text{sign-dom}(u_{\delta}) = \text{sign-dom}(v^1)$ by construction of $H$ (and $H' \subseteq H$). Thus the points with trajectory ending with $B^\omega$ are in $H''$, and applying lemma 3, we know that their ultimate trajectory has at most $y - 1$ switches. Applying lemma 5 to $H''$, we obtain the second hand of the union. Now, $L_{\text{ult}}^N(H') \subseteq L_{\text{ult}}^N(H)$, and $L_{\text{ult}}^N(H) \subseteq C_1^*C_2^* \cdots C_y^*A^\omega \cup C_1^*C_2^* \cdots C_{y-1}^*B^\omega$ by Corollary 4.

However, we cannot immediately conclude that $\mathcal{L}(H)$ is regular. Though $N_H$ is finite and computable, and there are a finite number of prefixes $w$ of size $N_H$, we need to know which subset of $L_{\text{ult}}^N(H)$ can appear after a given $w \in \{A, B\}^{N_H}$. We compute this next.

\section{Regularity of the Language}

Let \(\{e^0, \ldots, e^z\} = P\) the extremal points of $H$. Let $w^p$ the function associated with each $e^p \in P$. We denote $y = Z(H) = Z((w^p)_{p \leq z})$. We will show the regularity of $\mathcal{L}(H)$ using an induction on $Z(H)$.

For $Z(H) = 0$, the regularity of $\mathcal{L}(H)$ is trivial as all the dominant coefficients have the same sign. Thus, by Corollary 4, the ultimate language is $L_{\text{ult}}^N(H) = A^\omega$ and then the language is $\mathcal{L}(H) = \bigcup_{w \in W} wA^\omega$; or the ultimate language is $L_{\text{ult}}^N(H) = B^\omega$ and the language is $\mathcal{L}(H) = \bigcup_{w \in W} wB^\omega$, for a finite set of $W \subseteq \{A, B\}^{N_H}$.

For $w \in \{A, B\}^{N_H}$, consider $H_w = \{\delta \in H \mid \rho_\delta = w\}$, i.e., the language of words which begin with the prefix $w$. It is easy to see that $H_w \subseteq H$ is a polytope. Hence $Z(H_w) \leq Z(H)$. Observe that $\mathcal{L}(H) = \bigcup_{w \in (A, B)^{N_H}} \mathcal{L}(H_w)$. To show the regularity of $\mathcal{L}(H)$, we show the regularity of $\mathcal{L}(H_w)$ for each of the finitely many $w \in \{A, B\}^{N_H}$. For each $w \in \{A, B\}^{N_H}$, we have two cases: either $Z(H_w) < Z(H)$; then we apply the induction hypothesis and we are done. Or else, $Z(H_w) = Z(H) = y$. In this case, the sketch of proof is as follows:

\begin{itemize}
  \item We show that there exists $J$ such that for all $i \leq y$ and all $j \geq J$, we have a point $h_j^i$ in $H_w$ with trajectory $wC_1^iC_2\cdots C_{i-1}^iC_j^i$. This is shown by applying lemma 5 to each face $(f^0, \ldots, f^y)$ of $H$ and then using convexity arguments and the fact that $Z(H_w) = Z(H)$.
  \item Subsequently, denoting $H'$ the convex hull of $h_y^0 \cdots h_y^y$, we will deduce that $\mathcal{L}(H')$ is a regular language of the form $wC_1^iC_2^iC_3^i\cdots C_{i-1}^iC_i^i$.
  \item Partitioning $H_w \setminus H'$ into a finite set of polytopes, we obtain polytopes of lower switching-dimensions, which have regular languages by induction.
  \item We conclude since the finite union of these regular languages is a regular language, namely $\mathcal{L}(H_w)$.
\end{itemize}
We now formalize the above proof sketch in a sequence of lemmas whose proofs are relegated to the appendix. For all faces $F$ of $H$, applying Lemma 5 gives for all $j \in \mathbb{N}$, a point $g_j(F)$ of the convex hull of $F$ with trajectory $w_jC_1^jC_2^jC_3^j \ldots C_y^j$, for some $w_j \in \{A, B\}^{N_H}$. We now prove that $(g_j)$ converges towards $f^y$, the point of $F$ with lowest dominant factor.

Lemma 7. For every face $F = (f^0, \ldots, f^y)$ of $H$, $(g_j(F))_{j \in \mathbb{N}}$ converges towards $f^y$ as $j$ tends to infinity.

For all $j$, we consider $F(y, j)$ the convex hull of $\{g_j(F) \mid F \text{ is a face of } H\}$. Every point of $F(y, j)$ has trajectory $w'C_1^jC_2^jC_3^j \ldots C_y^j$ for some $w' \in \{A, B\}^{N_H}$. We then show by convexity that $H_2$ intersects $F(y, j)$, i.e., it has a point with trajectory $w'C_1^jC_2^jC_3^j \ldots C_y^j$.

Lemma 8. For $w \in \{A, B\}^{N_H}$ with $Z(H_w) = Z(H)$, there exists $J$ s.t. for all $j > J$, $F(y, j) \cap H_w \neq \emptyset$.

Similarly, for all $i \leq y$ we can define a polytope $F(i, j)$. All the points in $F(i, j)$ have trajectory $w'C_1^jC_2^jC_3^j \ldots C_y^j$ for some $w' \in \{A, B\}^{N_H}$. We can find a $J$, and a point $h_j \in H_w$ with trajectory $w'C_1^jC_2^jC_3^j \ldots C_y^j$ for all $i \leq y$ and all $j > J$. Now, as the number of $i \leq y$ is bounded, one can find such a $J$ uniform over all $i \leq y$ (by taking maximum over all $i$).

Consider $F(J)$ the convex hull of $F(0, J), \ldots, F(y, J)$. By convexity, all the points in $F(J)$ have their $n$-th letters of trajectory as $C_1$ for all $n \in \{N_H + 1 \ldots N_H + J\}$, since this is true for all points of $F(i, J)$. Hence, the language of $H_w \cap F(J)$ is included into $wC_1^jC_1^jC_2^jC_y^j \cup wC_1^jC_2^jC_3^j \ldots C_y^j$, because of the bound on the number of alternations after $N_H$ of trajectories from points of $H$ (Lemma 3). We show now that we have equality.

Lemma 9. The language of the convex hull of $\{h_n^y, \ldots, h_n^y\}$ is exactly $wC_1^jC_2^jC_3^j \ldots C_y^jC_y^j \cup wC_1^jC_2^jC_y^j \ldots C_y^jC_y^j$.

Hence the language of $H_w \cap F(J)$ is $wC_1^jC_2^jC_y^j \cup wC_1^jC_2^jC_y^j$.

Next, we note that the set $H_w \setminus F(J)$ may not be convex. However, one can partition $H_w \setminus F(J)$ into a finite number of convex polytopes. Now, let $G$ be a convex polytope in $H_w \setminus F(J)$. We want to show that $Z(G) < Z(H_w) = Z(H) = y$. Indeed, else, one could apply Lemma 8 to $G_w = G$ and for some $J'$ obtain $F(i, j) \cap G \neq \emptyset$ for any $j > J'$, which contradicts $G$ being a convex set in $H_w \setminus F(J)$.

Hence one can compute the language of every $G$ inductively, and each of them is regular. Finally, this leads to the regularity of $L(H_w)$ by finite union, and to the regularity of $L(H)$, and again by finite union to the regularity of $L(Init)$. This concludes our proof of the main regularity result, i.e., Theorem 4.

6 Irregularity of the symbolic dynamics

In this section, we will prove that symbolic dynamics of uPA can produce irregular languages even when eigenvalues of the transition matrix are distinct roots of real numbers. We prove this by constructing such a uPA and choosing the set of initial distributions carefully.

Consider a uPA $A_1$ with 7 states $q_1, \ldots, q_7$, $Goal = \{q_7\}$, and the following transition matrix:

$$M_1 = \begin{bmatrix}
0 & 1 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 1 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 1 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 1 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 1 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & 1 \\
\end{bmatrix}$$

$$\begin{bmatrix}
\frac{1}{512} & \frac{r+3}{512} & \frac{3r+3}{64} & \frac{13+16r}{128} & \frac{9+2r}{32} & \frac{1+r}{16} & \frac{1-r}{2} \\
\end{bmatrix}$$
On Regularity of unary Probabilistic Automata

where \( r = \cos(\pi/8) = \sqrt{2 + \sqrt{2}}. \)  
Eigenvectors of \( M_1 \) are \( 1, \frac{1}{\sqrt{2}} e^{\pm i \pi/4}, \frac{1}{\sqrt{2}} e^{\pm 3i \pi/4} \), and \( \frac{1}{4} e^{\pm 7i \pi/8} \),
which are distinct roots of real numbers. We choose \( \gamma = \sum_{q \in \text{Goal}} \delta_{\text{stat}}(q) = \delta_{\text{stat}}(q) = \frac{512}{65(17+8\cos(\pi/8))} \) (for any other choice of \( \gamma \), the language is regular by Lemma 11).

Let \( \delta \) be the initial distribution and \( M_1^0 \delta \) be the distribution after \( n \) steps of \( M_1 \). We consider a basis of eigenvectors such that the eigenvector corresponding to eigenvalue 1 is the stationary distribution and the remaining eigenvectors are normalized such that the \( 7^{th} \) component of each eigenvector of \( M_1 \) is non-zero. Now, by eigenvalue decomposition:

\[
M_1^0 \delta(7) = \mu_0 + \frac{M_1}{2\gamma}(e^{n \pi/2} + e^{-n \pi/2}) + \frac{P^2}{(2\sqrt{2})^n} \left( e^{3n \pi/4} + e^{-3n \pi/4} \right) + \frac{\mu_3}{4^n} (e^{n7\pi/8} + e^{-n7\pi/8})
\]

where \( \mu_0 = \gamma \) and \( \delta \) written in the eigenvector basis is \((1, \mu_1, \mu_2, \mu_2, \mu_3, \mu_3) \).

Consider the initial set of distributions \( \text{Init} \) to be the line segment (\( P1, P2 \)) where \( P1 = (1,a,a,b,b,c,c) \) and \( P2 = (1,0,0,b,b,c,c) \) in the eigenvector basis, where \( a = \frac{\cos(3\pi/8)}{2^{1/4}}, b = \frac{1}{2\sqrt{2}}, c = \frac{1}{2\sqrt{2} \cos(3\pi/8)} \). These values are chosen so that \( \mu_0 \) dominates over the other terms in the above equation, which ensures that \( P1 \) and \( P2 \) correspond to valid distributions in the standard basis. Note that \( \text{Init} \) is the set of convex combinations of distributions \( P1 \) and \( P2 \).

Now, we can show our main theorem of this section, whose details are in the appendix:

\[ \begin{align*}
\text{Theorem 10.} & \quad \mathcal{L}(\text{Init}, A_1) \text{ is not regular.} \\
\text{Proof sketch.} & \quad \text{Let } L = \mathcal{L}(\text{Init}, A_1). \text{ For } x, y, z, k \in \mathbb{N}, \text{ we define } L^k_{x,y,z} = \{ w \in \Sigma^\omega \mid \exists w' \in L, \forall i \in \mathbb{N}, (w'_{k+i} = w_{3+i+1}, w'_{k+i+1} = w_{3+i+2}, w'_{k+i+2} = w_{3+i+3} ) \}. \\
& \quad \text{That is, for every } a_1a_2a_3\ldots \in L, a_1a_2a_3a_4a_5a_6a_7a_8a_9a_{10} \ldots \in L^k_{x,y,z} \text{ where } x, y, z \leq k. \\
& \quad \text{It is easy to see that if } L^k_{x,y,z} \text{ is non-regular, so is } L. \text{ Now we can show that } L_{2,3,4}^{16} = \{(ABB)^2(AAB)^y(BAA)^w : y \geq 0 \}. \text{ As the range of } y \text{ is } [1, \infty) \text{ and } g(\mu_1, \mu_2, \mu_3) \text{ is a bounded function, hence } L_{2,3,4}^{16} \text{ is not regular. Thus, } L \text{ is not regular which completes the proof.} \end{align*} \]

\[ \begin{align*}
7 & \quad \text{Conclusion} \\
& \quad \text{Though unary Probabilistic Automata (or Markov Chains) are a simple formalism, there are still many basic problems, whose decidability is open and thought to be very hard. Indeed, it is surprising yet significant that even after assuming strong hypotheses, their behaviors cannot be described easily. In this paper, we proposed a class of unary probabilistic automata, for which all properties of some logic, e.g. } LTL \text{ are decidable even considering an infinite set of initial distributions. This allows for instance to check for the robustness of the behavior wrt. some property (e.g. positivity) for behaviors around a given initial distribution. Further, while we proved our results with respect to a single hyperplane (above is A, below is B), we can generalize these to more general settings as well. Finally, we showed that relaxing the assumptions immediately leads to non-regularity.} \\
& \quad \text{Acknowledgement: We would like to thank Manindra Agrawal and P.S. Thiagarajan for very fruitful discussions.} \end{align*} \]

On Regularity of unary Probabilistic Automata

Appendix

We recall that $\gamma_{\text{stat}} = \sum_{q \in \text{Goal}} \delta_{\text{stat}}(q)$.  

Lemma 11. For $\gamma \neq \gamma_{\text{stat}}$, we have $\mathcal{L}_{\text{Init}}(A)$ is regular.

Proof. For all distributions $\delta$, we have that $M^n\delta$ is converging (uniformly over all initial distributions [1]) towards $\delta_{\text{stat}}$ as $n$ tends to infinity. Hence for all $\gamma \neq \sum_{q \in \text{Goal}} \delta_{\text{stat}}(q)$, there exists a $N$ (independent of $\delta$) such that either for all $n \geq N, \delta \in \text{Init}$, $M^n\delta$ will be strictly above $\gamma$, or for all $n \geq N, \delta \in \text{Init}$, $M^n\delta$ will be strictly below $\gamma$. This gives $\mathcal{L}_{\text{Init}}(A) = S_1.A^\omega + S_2.B^\omega$ where $S_1$ and $S_2$ are finite sets of finite words of length $< N$. Hence $\mathcal{L}_{\text{Init}}(A)$ is regular.

Lemma 12. Given a matrix $M$ with distinct eigenvalues $(p_0,p_1,\ldots,p_k)$, we have $p_\delta(n) = A$ iff $\sum_{i=0}^k a_i(\delta)p_i^n \geq \gamma$ for some constants $a_i(\delta)_{1 \leq k}$ independent of $n$.

Proof. As the eigenvalues are distinct the eigenvectors $(v_i)_{1 \leq k}$ form a basis. Let $\delta = \alpha_v v_i$. By definition $p_\delta(n) = A$ iff $\sum_{q \in \text{Goal}} [M^n\delta](q) \geq \gamma$. This happens iff $\sum_{q \in \text{Goal}} \sum_{i=0}^k a_i M^n v_i e_q \geq \gamma$ if $\beta_n \sum_{q \in \text{Goal}} \sum_{i=0}^k a_i v_i e_q \geq \gamma$. Now fixing $a_i(\delta) = \sum_{q \in \text{Goal}} \alpha_v v_i e_q$, we have $p_\delta(n) = A$ iff $\sum_{i=0}^k a_i(\delta)p_i^n \geq \gamma$. Hence Proved.

Proofs of Section 4

Let $u^0, \ldots, u^z$ be $z + 1$ functions of type $k$.

Lemma 3. There exists a $N_{\text{max}} \in \mathbb{N}$ such that for all $\lambda_i \in [0,1]$ with $\sum \lambda_i = 1$, denoting $u(x) = \sum_{i=0}^z \lambda_i u^i(x)$, $u(x)$ has at most $Z(u^0,\ldots,u^z)$ zeros after $N_{\text{max}}$. Further, if $u(x)$ has exactly $Z(u^0,\ldots,u^z)$ zeros after $N_{\text{max}}$, then its sign changes exactly $Z(u^0,\ldots,u^z)$ times (that is, its zeros are not local maximum/minimums).

Basically, we want to show that $u(x)$ behaves like a polynomial of degree $Z(u^0,\ldots,u^z)$ (because it has $Z(u^0,\ldots,u^z)$ dominating factors). Define $\ell(i) = \text{dom}(u_i)$. We actually prove that the coefficients $a_j^i p_j^i$ of $u^i$ for all $j > \ell(i)$ play a negligible role wrt $a_j^i p_j^i$. To do so, we use derivatives to study the sign of $u(x)$, which is a linear combination of $z + 1$ functions, $u^i$ for all $0 \leq i \leq z$. Dividing $u(x)$ by a well chosen positive coefficient (of the form $p^i$) before differentiation allows us to obtain a linear combination of $z$ functions. An induction allows us to conclude.

Proof. For all $r \in \mathbb{N}$, we introduce a small constant $\varepsilon(r) > 0$ depending on the number $r$ of functions considered. We start by defining $m(r,q_0,\ldots,q_k) > 0$, the min over all $0 \leq r \leq s \leq z$ and $0 \leq j \leq k$ with $j \neq \ell(r)$ of $\frac{\log \frac{\ell(r)}{\ell(s)}}{\log \frac{\ell(r)}{\ell(j)}}$. The min exists and it is strictly positive because it is among a finite number of values, all strictly positive. We now define recursively $\varepsilon: \{0,\ldots,z\} \times \mathbb{R}_{\geq 0} \rightarrow \mathbb{R}_{> 0}$:

- $\varepsilon(z,q_0,\ldots,q_k) = \frac{1}{z!}$ and
- for all $0 \leq r < z$, $\varepsilon(r,q_0,\ldots,q_k) = \frac{m(r,q_0,\ldots,q_k)}{(1+3\varepsilon)(z-r)} \varepsilon(r+1,q_0,\ldots,q_k)$.
It is now easy to show by induction that for all $q \notin \{p_0, \ldots, p_k\}$, for all $r$, $\varepsilon(r, p_0, \ldots, p_k) = \varepsilon(r, p_0, \ldots, p_k)$. We then define $\varepsilon(r) = \varepsilon(r, p_0, \ldots, p_k)$ for all $0 \leq r \leq z$. We can also show by induction that for all $r$, $\varepsilon(r) \leq \frac{1}{2^r}$.

We will use the following technical lemma, which we prove later.

**Lemma 13.** Let $I$ be an interval of $\mathbb{R}_{\geq 0}$. Let $q_0 > \cdots > q_k > 0$ be positive reals. Let $v^i(x) := b_0^i q_0^k + b_1^i q_1^k + \cdots + b_k^i q_k^k$ be a function of type $k$ for all $i \in \{r, \ldots, z\}$, $0 \leq r \leq z$, s.t.,

- for all $i \in \{r, \ldots, z\}$, all $j \neq \ell(i)$ and all $x \in I$, $|b_j^i q_j^k| \leq |\varepsilon(z, q_0, \ldots, q_k) b_{\ell(i)}^i q_{\ell(i)}^k|$ (if this holds, we say that $|b_j^i q_j^k|$ is negligible w.r.t $|b_{\ell(i)}^i q_{\ell(i)}^k|$ and call this the negligibility hypothesis).

Then for all $\lambda_0 \geq 0, \ldots, \lambda_z \geq 0$ with $\sum_{i=r}^z \lambda_i = 1$, the function $v : x \mapsto \sum_{i=r}^z \lambda_i v^i(x)$ has at most $Z(b_{\ell(i)}^i q_{\ell(i)}^k, \ldots, b_{\ell(z)}^z q_{\ell(z)}^k)$ zeros in $I$. Further, if $v(x)$ has exactly $\sum_{i=r}^z \lambda_i v^i(x)$ zeros in $I$, then its sign changes exactly $Z(b_{\ell(i)}^i q_{\ell(i)}^k, \ldots, b_{\ell(z)}^z q_{\ell(z)}^k)$ times (that is, its zeros in $I$ are not local maximum or minimum).

Notice that in Lemma 13, $\ell(i)$ is the dominating factor for $u^i$. That is, in the case where $I$ is bounded, then it may not be the case that $\ell(i)$ is the dominating factor of $v^i$, if for instance a constant $b_j^i$ is extremely big.

Assume Lemma 13 has been proved. We then apply Lemma 13 with $r = 0$, $v^i = u^i$ for all $i \leq z$ and $I = [N_{max}, \infty)$, with $N_{max}$ chosen such that the negligibility hypothesis is verified, which is possible as $\ell(i)$ is the dominating factor of $u^i$ for all $i$. This implies that $u$ has $Z(b_{\ell(i)}^i q_{\ell(i)}^k, \ldots, b_{\ell(z)}^z q_{\ell(z)}^k) = Z(u^0, \ldots, u^z)$ many zeros, since these are the dominant coefficients of the $u^i$. Thus, we obtain the statement of Lemma 3: for all $\lambda_i \in [0, 1]$ with $\sum_i \lambda_i = 1$, denoting $u(x) = \sum_{i=0}^z \lambda_i u^i(x)$, $u(x)$ has at most $Z(u^0, \ldots, u^z)$ zeros after $N_{max}$. Further, if $u(x)$ has exactly $Z(u^0, \ldots, u^z)$ zeros after $N_{max}$, then its sign changes exactly $Z(u^0, \ldots, u^z)$ times (that is, its zeros are not local maximum/minimums). This completes the proof of Lemma 3.

It now remains to prove the technical lemma, which we do by induction on $r$.

**Proof of Lemma 13.** For $r = z$, the lemma is trivial as one has a unique function $v^z(x) := b_z^z q_z^k$. Let $\ell = \ell(z)$. For all $x \in I$, we have $\sum_{i=1}^z |b_i^z p_i^z| \leq k \varepsilon(z, q_0, \ldots, q_k)|b_{\ell}^z p_{\ell}^z| \leq k \frac{1}{2^r} |b_{\ell}^z p_{\ell}^z|$. Hence the sign of $v^z(x)$ is the sign of $b_{\ell}^z$ for all $x \in I$. That is, $v^z$ has no zero in $I$. The further statement is thus trivially verified in this case.

Let $0 \leq r \leq z$. Assume that the lemma is true for all instances with functions $v^{r+1}, \ldots, v^z$ is true. Let us prove that the lemma is true for all instances with functions $v^r, \ldots, v^z$.

Let $v^r(x) := b_0^r q_0^k + b_1^r q_1^k + \cdots + b_q^r q_k^k$, for $i \in \{r, \ldots, z\}$ such that $1 \geq q_0 > q_1 > \cdots > q_k > 0$, $|b_j^r q_j^k| \leq |\varepsilon(r, q_0, \ldots, q_k) b_{\ell(i)}^i q_{\ell(i)}^k|$ for all $j \neq \ell(i)$ and $x \in I$. This hypothesis ensures that for all $i$, $(1 - k \varepsilon(r, q_0, \ldots, q_k)|b_{\ell(i)}^i q_{\ell(i)}^k| \leq |v^r(x)| \leq (1 + k \varepsilon(r, q_0, \ldots, q_k)|b_{\ell(i)}^i q_{\ell(i)}^k|$). As we have $\varepsilon(r, q_0, \ldots, q_k) \leq \frac{1}{2^r}$ for all $r$, it gives

$$\frac{1}{2} |b_{\ell(i)}^i q_{\ell(i)}^k| \leq |v^r(x)| \leq \frac{3}{2} |b_{\ell(i)}^i q_{\ell(i)}^k|$$

(1)

Let $\lambda_1 \geq 0, \ldots, \lambda_z \geq 0$ with $\sum_{i=z}^z \lambda_i = 1$. Take the maximal $x_y \in I$ such that $v(x_y) = \sum_{r \leq z} \lambda_i v^r(x_y) = 0$ (if there is no such zero, then we are done). We can assume without loss of generality that $\ell(r) \neq \cdots \neq \ell(z)$, else it is easy to merge several $u^i$ with the same $\ell(i)$ together. We have $|\ell_i v^r(x_y)| = |\sum_{i=r}^z \lambda_i v^r(x_y)|$ because $x_y$ is a zero of $v$. Taking $s > r$ with $|\lambda_s v^s(x_y)|$ maximal, we have $|\sum_{i=r}^z \lambda_i v^r(x_y)| \leq z \lambda_s |v^s(x_y)|$. Thus $|\ell_i v^r(x_y)| \leq z \lambda_s |v^s(x_y)|$. 

\end{document}
We let $I' = I \cap [0, x_y]$. Using (1) for $v'$ and for $v^s$ at $x_y \in I$, we have $\lambda_i |b'_{r(i)}| q_{r(i)}^x \leq \lambda_i 3z |q_{r(i)}^x| b'_{r(i)}$.

Now, because $q_{r(i)} > q_{r(i)}$, we have for all $x \in I'$: $\lambda_i |b'_{r(i)}| q_{r(i)}^x \leq \lambda_i 3z |q_{r(i)}^x| b'_{r(i)}$. By applying the hypothesis of the negligibility, we thus get for all $x \in I'$ and all $j \neq \ell(r)$, $\lambda_i |b'_{j} q_{r(i)}^x \leq \lambda_i 3z c(r(y_0, \ldots, y_{\omega})) b'_{r(i)} q_{r(i)}^x$. That is, the terms $\frac{\lambda_i}{\lambda_j} b'_{j} q_{r(i)}^x$, with $j \neq \ell(r)$ are small wrt $b'_{r(i)} q_{r(i)}^x$ for $x \in I'$.

Let $q = q_{r(i)}$ and consider the function $v'(x) = \frac{v(x)}{q}$. Functions $v'$ and $v$ have the same zeros. We can derive $v'$, which will cancel out every term using $q^x$: For all $r \leq i \leq z$, we define functions $f^i(x) := c_{j} \left( \frac{1}{q} \right)^x + c_{j} \left( \frac{1}{q} \right)^x + \cdots + c_{j} \left( \frac{1}{q} \right)^x$ with:

1. For $i \neq s$, $f^i$ is the derivative of $v'$, that is $c_{j} = \log(\frac{1}{q}) b'_{j}$ for $j \neq \ell(r)$, and $c_{\ell(r)} = 0$.
2. $c_{j} = \log(\frac{1}{q}) b'_{j}$ for $j \neq \ell(r)$, and $c_{\ell(r)} = 0$.

It is easy to check that $f(x) = \sum_{i=1}^{z} \lambda_i f_i(x)$ is the derivative of $v'$. We now prove the inequalities involving $\varepsilon$ for $f'(x)$ for all $x \in I'$. We do it for the most complex term, ie $c^r_j$ with $j \neq \ell(s), \ell(r)$. We have $|c^r_j| \left( \frac{1}{q} \right)^x = |\log(\frac{1}{q})||b'_{j} + \frac{1}{x} b'_j|| \left( \frac{1}{q} \right)^x \leq |\log(\frac{1}{q})|c(r,y_0, \ldots, y_{\omega}) \left( 1 + 3z \right) |b'_{r(i)}| \left( \frac{1}{q} \right)^x = |\log(\frac{1}{q})|m(r,y_0, \ldots, y_{\omega}) \leq \varepsilon(r + 1, y_0, \ldots, y_{\omega}) |c^r_j| \left( \frac{1}{q} \right)^x$ by definition of $m(r)$. Recalling that $c(r + 1, y_0, \ldots, y_{\omega}) = c(r + 1, y_0, \ldots, y_{\omega})$. We conclude $|c^r_j| \left( \frac{1}{q} \right)^x \leq \varepsilon(r + 1, y_0, \ldots, y_{\omega}) |c^r_j| \left( \frac{1}{q} \right)^x$ for all $x \in I'$, so we can apply the lemma to $f^{i+1}, \ldots, f^z$. Thus function $f$ has at most $Z(c^{i+1}_{r(i+1)} q^{r(i+1)} q^{r(i)}), \ldots, c^{i}_{r(i)} q^{r(i)})$ zeros in $I'$. It is easy to see that $c^r_{i(i)}$ has the opposite sign of $b^r_{i(i)}$, and then we obtain $Z(c^{i+1}_{r(i+1)} q^{r(i+1)} q^{r(i)}), \ldots, c^{i}_{r(i)} q^{r(i)}) = Z(b^r_{i(i+1)} q^{r(i+1)} q^{r(i)}), \ldots, b^r_{i(i)} q^{r(i)}).

Now, consider $v'$. It has the same sign and zeros as $v$. Hence the last zero of $v'$ in $i$ is $x_y$. Because its derivative is $f$, $v'$ (and thus $v$) has at most $1 + Z(b^r_{i(i+1)} q^{r(i+1)} q^{r(i)}), \ldots, b^r_{i(i)} q^{r(i)})$ zeros in $I'$. If $Z(b^r_{i(i+1)} q^{r(i+1)} q^{r(i)}), \ldots, b^r_{i(i)} q^{r(i)}) = 1 + Z(b^r_{i(i+1)} q^{r(i+1)} q^{r(i)}), \ldots, b^r_{i(i)} q^{r(i)}),$ (or if $v$ has at most $Z(b^r_{i(i+1)} q^{r(i+1)} q^{r(i)}), \ldots, b^r_{i(i)} q^{r(i)}),$ the induction proof is finished.

Else, we proceed by contradiction. It means that the sign of $b^r_{i(i+1)}$ and of $b^r_{i(i+1)}$ is the same. It also means that $f$ has exactly $Z(b^r_{i(i+1)} q^{r(i+1)} q^{r(i)}), \ldots, b^r_{i(i)} q^{r(i)})$ zeros and switches sign every time. Without loss of generality, assume that $b^r_{i(i+1)} > 0$. By induction, it is easy to see that the sign of $f(x_{y_y})$ is the sign of $c^r_{i(i+1)}$, which is strictly negative.

In the same way, $\ell(r)$ is the dominating factor of $v(x)$ in $I$, just after $x_y$ (remember that $v(x_y) = v'(x_y) = 0$, the sign of $v$ is $b^r_{i(i)} > 0$). This contradicts the continuity of $v$ and the fact that $v(x_y) = 0$ and that its derivative is negative.

For the second statement, assume that $v$ has exactly $\alpha := Z(b^r_{i(i+1)} q^{r(i+1)} q^{r(i)}), \ldots, b^r_{i(i)} q^{r(i)})$ zeros in $I$. We know by the above that the derivative has exactly $\alpha - 1$ zeros $y_i, \ldots, y_{\omega-1}$ in $I'$. For all $i \in \{1, \alpha - 1\}$ there is one zero $x_i$ of $v$ between two consecutive zeros $y_i, y_{i+1}$ of the derivative. Now, if by contradiction $v$ does not change sign at one of its zeros, let say $x_i$, it means that $x_i = y_i$. In particular, it means that in $(y_i, y_{i+1}]$, there is no zero of $v$, which contradicts the fact that $v$ has exactly $\alpha$ zeros in $I'$. It is also the case if the derivative is null at $x_y$. Last, $v$ being continuous, it cannot change sign after $x_y$ as it has no zero other than $x_y$ (by definition of $x_y$).

Lemma 5. For all $n_1, n_2, \ldots, n_y \in \mathbb{N}$ there exist $\lambda_i \in [0, 1]$ with $\sum_{i=1}^{\gamma} \lambda_i = 1$, such that denoting $u(x) = \sum_{i=1}^{\gamma} \lambda_i v^i(x)$, $L(u) = w A^{n_1} B^{n_2} \cdots B^{n_y} A^w$ (for $w$ even) for some prefix $w \in \{A, B\}^N$ of size $|w| = N_H$.

Proof. Let $N_{max} < n_1 < \cdots < n_y$ be integers. We define inductively $x_0 = N_{max} + 1/2$ and $x_j := x_{j-1} + n_j$ for all $1 \leq j \leq y$ if $n_j \neq 0$ and $x_j := x_{j-1} + \frac{1}{2y}$ if $n_j = 0$.  

\end{document}
Lemma 8. Let $D = \{v_i, v_{i+1}, \ldots, v_{i+j}\}$, such that $v_{i+k}(x_k) = 0$ for all $k \in \{1, \ldots, j\}$. Further, if $i$ is odd (resp. even), we have $v_i(x) > 0$ (resp. $v_i(x) < 0$) for all $x > x_j$. The initialization is trivial: we have that $\forall x > N_{\text{max}}, v_i(x)$ is positive (resp. negative) when $i$ is odd (resp. even), by choice of $N_{\text{max}}$.

Induction step: Let $0 < j < y$. Assume that we have built $v_i^{j-1}(x)$ for all $i$. The first thing to remark is that for all $i$, any convex combination of $v_i^{j-1}(x)$ and $v_i^{j+1}(x)$ will have a zero at $x_1, \ldots, x_{j-1}$ as both term are zero there. It remains to choose one which also have a zero at $x_j$. By induction, $\forall x > x_{j-1}, v_i^{j-1}(x)$ is positive (resp. negative) when $i$ is odd (resp. even). Thus it exists $\lambda_i^j \in (0, 1)$ such that $\lambda_i^j v_i(x_j) + (1 - \lambda_i^j) v_{i+1}(x_j) = 0$. We thus define $v_i(x) = \lambda_i^j v_i(x) + (1 - \lambda_i^j v_{i+1}(x)$ and it has the required $j$ zeros, which are all after $N_{\text{max}}$.

As it is a linear combination of $v_1 \cdots v_{i+j}$, it has exactly $j$ zeros after $N_{\text{max}}$ (by lemma 3), and thus $\forall x > N_j, v_i(x)$ is positive (negative) if $i$ is odd (even) (as it has no zero after $x_j$ and we know its asymptotic behavior).

Then $v_i^j$ has $\{x_1, \ldots, x_j\}$ as zeros, and by lemma 3, it switches sign each time. Hence the language of $v_i^j$ is $wA^{n_1}B^{n_2} \cdots A^\omega$ (or $wB^{n_1}A^{n_2} \cdots A^\omega$ if $y$ odd) for some prefix $w$ of size $|w| = N_{\text{max}}$. ▶

Proofs of section 5

Let $i \leq y = Z(H)$. A $i$-subface of $H$ is a subset $F = (f^0, \ldots, f^i)$ of the set $P$ of extremal points of $H$ such that $Z(F) = i$.

Lemma 7. For every $i \leq y$ and every $i$-subface $F_i = (f^0, \ldots, f^i)$ of $H$, $(g_j^i(F))_{j \in \mathbb{N}}$ converges towards $f^i$ as $j$ tends to infinity.

Proof. For $i = 0$, the result is trivial. Let $0 < i \leq y$. By contradiction, assume that there exists a dimension $d$ (as there is a finite number of dimensions) and an infinite set $J$ of indices $j \in \mathbb{N}$ such that $g_j^i$ is bounded away from $f^i$ on dimension $d$. Let $b$ be this bound. Let $H'$ be the convex polytope made of points of the convex hull of $F_i$ at distance at least $b$ from $f^i$ on dimension $d$ ($g_w^i$ is an extremal point of $H$, hence there is only one direction of being at distance at least $b$ on dimension $d$). Applying lemma 3 to $H'$, we obtain a bound $N_{H'}$ such that the number of switches after $N_{H'}$ (in general, $N_{H'} > N_H$) of any point of $H'$ is at most $i - 1$, as $Z(H') < Z(F_i) = i$. Now, as $J$ is infinite, one can find a $j \in J$ with $j > N_{H'} + 1$. We have that the trajectory of $g_j^i \in H'$ is $w'C_j^1C_j^2 \cdots C_j^i$ for some $w' \in \{A, B\}^{N_{H'}}$, which switches signs $i$ times after $N_{H'}$, a contradiction. ▶

In the same way, for all $r < i$, we can prove that denoting $d_j^{i,r}$ the distance of $g_j^i$ to the convex hull of $(f^0, \ldots, f^r)$, we have $d_j^{i,r+1}/d_j^{i,r}$ converges towards 0 as $j$ tends to infinity. Let $D(e, f^0, \ldots, f^{r+1})$ be the distance from $e$ to the convex hull of $(f^0, \ldots, f^{r+1})$ divided by the distance from $e$ to the convex hull of $(f^0, \ldots, f^r)$. We thus want to show that $D(g_j^i, f^0, \ldots, f^{r+1})$ tends towards 0.

First, for $r = i - 1$, this is trivial as $d_j^{i,i-1} = 0$ for all $i, j$. Else, for $r < i - 1$, if it was not the case, there would exist a bound $b$ and an infinite set $J$ of indices with $d_j^{i,r+1}/d_j^{i,r} > b$ for all $j \in J$. Then as above, by considering $H'$ the convex polytope made of points $e$ of the convex hull of $F_i$ with $D(e, f^0, \ldots, f^{r+1}) > b$, we have $Z(H') < Z(F_i) = i$ and the same contradiction as above applies.

Lemma 8. Let a convex $H' \subseteq H$ and $w \in \{A, B\}^{N_{H'}}$ with $Z(H'_w) = Z(H')$. There exists $J$ s.t. for all $j > J$, $F(y, j) \cap \text{Closure}(H'_w) \neq \emptyset$. ▶
On Regularity of unary Probabilistic Automata

Proof. Let \( y \) be a point in \( H_w \) such that \( Z(H_w) = y \). We choose \( J \) such that for all face \( F = (f^0, \ldots, f^y) \) of \( H \), for all \( j > J \),
\[ g^y_j(F) \text{ is closer to } f^y \text{ than any } h^r \text{ is from } h^y, \ i \neq y. \]
\[ \text{for all } r \text{ and all } k > r, \ D(g^y_j(F), f^0, \ldots, f^y) < D(h^k, h^1, \ldots, h^r) \]
Then we have that \( Closure(H_w) \) intersects the convex hull of \( (g^y_j(F))_{F \text{ a face of } H} \).

As \( g^y_j(F) \in F(y, j) \) for all \( F \), we have In particular \( F(y, j) \cap Closure(H_w) \neq \emptyset. \)

Next, we prove Lemma 9 for which we first need an intermediate lemma describing the exact language of the convex hull of two points of \( H_w \). In the following, we will abuse notation of a point to also define the function associated with its trajectory: \( g(n) \geq 0 \) iff the \( n \)-th letter of the trajectory starting from \( g \) is an \( A \).

Lemma 14. Let \( e_0, \ldots, e_y \) be points of \( H_w \) with \( Z(e_0, \ldots, e_y) = Z(H_w) \). Assume that the trajectory of \( e = e_k \) is \( wC_1^i C_2^i \cdots C_{k-1}^i C_k^w \) with \( i_j > 0 \) and \( \{j, j+1\} = \{A, B\} \) for all \( j < k \). Assume also that the trajectory of \( f = e_{k-1} \) is \( wC_1^i C_2^i \cdots C_{k-3}^i C_{k-1}^w \). Let \( i' > i_k-1 \).

Then there is a point \( g \) on the segment \((e, f)\) with \( g(\max_i \sum_{j=1}^{k-1} i_j + i' + 1/2) = 0 \).

Notice that any \( g \) on \((e, f)\) has at least \( k - 2 \) zeros, one in each \( (\max_i + i_j + \cdots + i_{j-3} + i_j + 1/2) \). The \( g \) we will build thus have trajectory \( wC_1^i C_2^i \cdots C_{k-1}^i C_k^w \).

Hence, the language of \([e, f]\) is \( wC_1^i C_2^i \cdots C_{k-1}^i C_k^w \).

Proof. Let \( i > N \). Let \( g \) define a point on \((e, f)\) to be specified later. For \( a \in \{e, f, g\} \), we define \( u_a \) as the function associated to the point \( a \). Let \( x := |w|+i_1+i_2+\cdots+i_{z-3}+i+1/2 \).

We have \( u_e(x) > 0 \) and \( u_f(x) < 0 \) (in the unlikely case where \( u_f(x) = 0 \) with this \( x \), i.e., \( u_f(x) = 0 \) implies the letter is \( B \) and the derivative of \( u_f \) is null in \( x \), we just take \( x = 1/4 \). Because of the maximal number of zeros of \( u_f \), \( u_f(x+1/4) \neq 0 \) if \( u_f(x) = 0 \). So there exists \( \lambda \in (0, 1) \) such that \( \lambda u_e(x) + (1-\lambda)u_f(x) = 0 \). Let \( g \) be the point \( \lambda e + (1-\lambda)f \) on segment \((e, f)\), and \( u_g \) its associated function. We have \( u_g = \lambda u_e + (1-\lambda)u_f \) by linearity. Further, as \( g = \lambda e + (1-\lambda)f \) and both \( e \) and \( f \) have prefix \( wA^1B^2A^3 \cdots A^{z-1} \), then \( g \) has also prefix \( wA^1B^2A^3 \cdots A^{z-1} \). It means that \( u_g \) changes sign between \( |w|+i_1-1 \) and \( |w|+i_1, \ldots, \) between \( |w|+i_1+i_2+\cdots+i_{z-3}-1 \) and \( |w|+i_1+i_2+\cdots+i_{z-3} \). In particular, \( u_g \) has a zero in every of these \( z-2 \) intervals. Thus \( u_g \) has \( z-1 \) zeros. By lemma 3, it switches signs exactly at these zeros, and never elsewhere in \([\max_i, +\infty)\). Thus the trajectory of \( g \) is \( wA^1B^2A^3 \cdots A^{z-1}B^2A^w \). Further, as \( g \) is on the segment \([e, f]\), both \( e, f \in H_w \) and \( H_w \) is convex, then \( g \in H_w \).

We can now finish the proof of lemma 9.

Lemma 9. Let \( e_0, \ldots, e_y \) be points of \( H_w \) with \( Z(e_0, \ldots, e_y) = Z(H_w) \). Let \( J \in \mathbb{N} \). Assume that the trajectory of \( e_i \) is \( wC_1^i C_2^i \cdots C_y^i \) with \( \{j, j+1\} = \{A, B\} \) for all \( j < i \) (that is \( e_i \) has the maximum number of alteration in its subspace). Then the language of the convex hull of \( \{e_0, \ldots, e_y\} \) is exactly \( wC_1^i C_2^i \cdots C_{y-1}^i C_y^w \cup wC_1^i C_2^i \cdots C_{y-2}^i C_{y-1}^w \).

Proof. We first consider the case \( wC_1^i C_2^i \cdots C_{y-1}^i C_y^w \). Then, we consider the other case of \( wC_1^i C_2^i \cdots C_{y-2}^i C_{y-1}^w \) in a second step.

Let \( x \) be a point in the interior of the convex hull of \( e_1 \cdots e_z \). Then the trajectory of \( x \) is \( wC_1^i u \) for some infinite word \( u \) as all the point \( e_1 \cdots e_z \) are of this type and by linearity of \( M^i \) for all \( i \). Now, by lemma 3, the number of alteration after \( w \) is at most \( z-1 \), hence the
trajectory of $x$ is of the form $wC_1^{i_1+i}C_2^{j_1}C_3^{i_2} \cdots C_{k-1}^{i_{k-1}} \cdots C_k^{j_k}$ with $i_j \in \mathbb{N}$ for all $j$. We will show that every of these trajectories is reached for a point in the convex hull of $e_1 \cdots e_z$.

Let $(i_1)_{1 \leq k \leq k}$ be a family of integers. At first, we assume that $i_j \neq 0$ for all $j$. For all $j \in \{1, \ldots, z-1\}$ let $x_j := N_{\text{max}} + i + j$. Also, for all $j \in \{1, \ldots, z-1\}$, we define $y_j := N_{\text{max}} + i + 1 + \ldots + i + j + 1/2$.

We will prove that there exists a point $f$ in the interior of the convex hull of $e_1, \ldots, e_z$ such that $f(y_j) = 0$ for all $j \in \{1, \ldots, z-1\}$. Then Lemma 3 will imply that the language of $f$ is $wC_1^{i_1+i}C_2^{j_1}C_3^{i_2} \cdots C_{k-1}^{i_{k-1}} \cdots C_k^{j_k}$.

We build $f$ by induction. Applying lemma 14 for all $j \in \{1, \ldots, z-2\}$ to $e_j, e_{j+1}$, we obtain a point $e_j^1$ in $(e_j, e_{j+1})$ such that $e_j^1(y_{j-1}) = 0$. As $e_j^1$ is in $(e_j, e_{j+1})$, by linearity, the prefix of its trajectory is $wC_1^{i_1+i}C_2^{j_1}C_3^{i_2} \cdots C_{j-1}^{j_1}C_j$ (and it ends up with $C_{j+1}^{j+1}$), which implies that it has additionally $j-1$ zeros in $(N_{\text{max}} + i, N_{\text{max}} + i + j + 1)$, with $N_{\text{max}} + i + j + 1 \leq y_{j-1}$.

Thus, the sign of $e_j^1(x)$ is constant in $x \in [x_{j-1} + 1, y_{j-1}]$, depending on the parity of $j$. In particular, $y_{j-1} - 2 \in [x_{j-1} + 1, y_{j-1})$ for all $j \leq z-2$.

We now consider points $(e_j^1)_{1 \leq j \leq z-2}$ in the convex hull of $(e_j^1)_{1 \leq j \leq z-2}$. Thus any of these points have $e_j^1(y_{j-1}) = 0$ by linearity. Let $j \in \{1, \ldots, z-3\}$. We chose $e_j^2$ in the segment $(e_j^1, e_{j+1})$ such that $e_j^2(y_{j-2}) = 0$. It is possible as the sign of $e_j^1(y_{j-2}) > 0$ and the sign of $e_{j+1}^1(y_{j-2}) < 0$ (or vice versa, depending on the parity of $j$). We have that $e_j^2$ has $j + 1$ zeros: $y_{j-1} - 2, y_{j-2}$ and one zero in every of $[x_k, x_{k+1})$ for all $k < j$.

By induction, we get $f := e_j^{z-1}$ such that $f(y_i) = 0$ for $1 \leq i \leq z-1$ and it switches sign between each zeros, hence its trajectory is $wC_1^{i_1+i}C_2^{j_1}C_3^{i_2} \cdots C_{z-1}^{i_{z-1}}C_z^{j_z}$. Hence the case for $i_j > 0$ for all $j$ is solved.

Consider now the case where some $i_j = 0$. First, if $i_1 = 0$, then the above procedure works. Now, for $i_j = 0$ for $j \neq 1$, it means that the desired trajectory is $wC_1^{i_1+i}C_2^{j_1} \cdots C_{j-1}^{j_1-1}C_{j+1}^{j_2} \cdots C_{z-1}^{i_z-1}C_z^{j_z} = wC_1^{i_1+i}C_2^{j_1} \cdots C_{j-2}^{j_1-2}C_{j+1}^{j_2+1} \cdots C_{z-2}^{i_z-2}C_z^{j_z}$ as $C_{j-1} = C_{j+1}$, hence with 2 less switches. It suffices to start with the above procedure, but with $z' = z-2$ and points $e_1, \ldots, e_{z'} = e_{z-2}$. For instance, take $e_1, e_2$. Their trajectories are respectively $wC_1^{i_1}$ and $wC_1^{i_2}$. Applying lemma 14, we get the existence of a point $f_1$ in the convex hull of $e_1, e_2$ with a zero in $y_1 = N_{\text{max}} + i + i_1 + 1/2$. Its trajectory is $wC_1^{i_1+i_2}C_2^{j_2}$.

First, for the case of $wC_1^{i_1+i_2}C_2^{j_2}C_3^{i_3} \cdots C_{k-2}^{i_{k-2}}C_k^{i_k}$, it suffices to proceed in the same way in the convex hull of $(e_0, \ldots, e_{y_1})$.

### Proofs of Section 6

In this section, we will prove Theorem 10, i.e., our non-regularity result. To do so we consider the uPA $A_1$ and associated Markov chain $M_1$ from Section 6. We construct a special language $L_{2,4}^{16}$ from $A_1$ and prove it irregular in Lemma 16, then we prove that irregularity of $L_{2,4}^{16}$ implies the irregularity of $L(\text{Init}, A_1)$ in Lemma 17.

**Lemma 15.** Consider the eigenvector of $M_1$ for eigenvalue 1, namely $w_1$, to be stationary distribution and others normalized by their 7th component i.e $w_1(7) = 1$ for all $i > 1$ (this is possible as none of the 7th components are 0, see Figure 2 for $w_2, \ldots, w_7$). This forms a basis which is the so-called eigenvector basis. Then $\delta$ in the eigenvector basis is $(1, \mu_1, \mu_2, \mu_3, \mu_3)$.

**Proof.** Considering $\delta$ in the eigenvector basis to be $\alpha$ and $w_1$ as the eigenvectors. $\delta = \sum_{i=1}^{7} \alpha_i w_i$. $\alpha_0$ is 1 as $\delta$ is a distribution and $w_1 = \delta_{\text{stat}}$ is the stationary distribution. Then,
\[ \delta = \delta_{\text{stat}} + \sum_{i=2}^{7} \alpha_i w_i, \quad M^n_i \delta = \delta_{\text{stat}} + \sum_{i=2}^{7} \alpha_i \lambda^n_i w_i. \]  
Finally, \( M^n_i (7) = \delta_{\text{stat}} (7) + \sum_{i=2}^{7} \alpha_i \lambda^n_i w_i (7). \)

But as we have normalized with respect to the 7th component we have \( w_i (7) = 1 \) for all \( i \in [2, 7]. \)

Hence, \( M^n_i (7) = \delta_{\text{stat}} (7) + \sum_{i=2}^{7} \alpha_i \lambda^n_i. \) Now, comparing \( u (n) \) to \( M^n \delta \) we get that \( \delta \) in the eigenvector basis is \((1, \mu_1, \mu_1, \mu_2, \mu_2, \mu_3, \mu_3)\).

Consider an infinite word \( w = (w_i)_{i=1}^{\infty} \) over a finite alphabet \( \Sigma. \) For a given language \( L \subseteq \Sigma^\omega, \) we define for \( x, k \in \mathbb{N}, x \leq k, \)

\[ L^k_x = \{ w \in \Sigma^\omega : \exists u' \in L \forall i \in \mathbb{N} \left( w'_{(k(i-1)+x)} = w_i \right) \} \]

Similarly, we define \( L^k_{xyz} \) for \( x, y, z, k \in \mathbb{N} \)

\[ L^k_{xyz} = \{ w \in \Sigma^\omega : \exists u' \in L \forall i \in \mathbb{N} \left( w'_{(k(i-1)+y)} = w'_i, w'_{(k(i-1)+z)} = w_3(i-1+3) \right) \} \]

Thus, for every \( a_1 a_2 a_3 \ldots \in L, \) we have \( a_{2k+2} a_{2k+3} a_{2k+4} \ldots \in L^k_y \) where \( x \leq k \) and further, \( a_{2k+2} a_{2k+3} a_{2k+4} \ldots \in L^k_{xyz} \) where \( x, y, z \leq k. \) Let us start by considering these languages for \( L_5 (A_1) \) for an arbitrary single point initial distribution \( \delta. \) To simplify notation, we will henceforth denote \( L^\delta = L_\delta (A_1). \) Note that these languages will be singleton sets. We will then vary \( \delta \) over \( \text{Init} \) to obtain the required irregular language.

Let \( v(m) = u(m) - \gamma. \) Then the \( m^{th} \) letter is \( A \) if \( v(m) > 0 \) and \( m^{th} \) letter is \( B \) if \( v(m) \leq 0. \) Now, for \( k = 16 \) consider \( L^k_{2,16}, L^k_{3,16}, L^k_{4,16} \) and \( L^k_{2,3,4} \) for getting \( L^k_i \) we need to put \( m = kn + i \) and for each \( i = 2, 3, 4 \) one term of \( v(m) \) vanishes as angle becomes \( \pi/2 \).

Thus, for \( L^k_{2,16}, \) \( m = 16n + 2 \) hence

\[
v(m) = \mu_1 \left( \frac{1}{4} \right) \left( \frac{1}{2} \right)^{16n} (e^{i\pi} + e^{-i\pi}) + \mu_2 \left( \frac{1}{8} \right) \left( \frac{1}{2\sqrt{2}} \right)^{16n} (e^{i\pi/2} + e^{-i\pi/2}) + \mu_3 \left( \frac{1}{16} \right) \left( \frac{1}{4} \right)^{16n} (e^{i\pi/4} + e^{-i\pi/4})
\]

\[
v(m) = \mu_3 \left( \frac{1}{8\sqrt{2}} \right) \left( \frac{1}{4} \right)^{16n} - \mu_3 \left( \frac{1}{2} \right) \left( \frac{1}{2} \right)^{16n}
\]

which will be negative eventually (as \( 1/4 < 1/2 \)) but positive initially. Let \( n_2 \) be the point at which it shifts from positive to negative. That is, for \( n \in [0, n_2] \) \( v(m) \geq 0 \) while for \( n \in (n_2, \infty) \) \( v(m) < 0. \) Now, we can compute \( n_2 \) as a function of \( \mu_1, \mu_2 \) i.e. \( n_2 = \left[ \frac{1}{16} \log_2 \left( \frac{\mu_3}{4\sqrt{2} \mu_1} \right) \right] \) if \( \frac{1}{16} \log_2 \left( \frac{\mu_3}{4\sqrt{2} \mu_1} \right) \) is not an integer and \( \left[ \frac{1}{16} \log_2 \left( \frac{\mu_3}{4\sqrt{2} \mu_1} \right) \right] - 1 \) otherwise. Note that \( n_2 \) can take any integer value by choosing \( \mu_1 \) and \( \mu_3 \) appropriately.

Similarly, for \( L^k_{3,16} \), we have \( m = 16n + 3 \) hence

\[
v(m) = \mu_1 \left( \frac{1}{8} \right) \left( \frac{1}{2} \right)^{16n} (e^{i\pi/2} + e^{-i\pi/2}) + \mu_2 \left( \frac{1}{16\sqrt{2}} \right) \left( \frac{1}{2\sqrt{2}} \right)^{16n} (e^{i\pi/4} + e^{-i\pi/4}) + \mu_3 \left( \frac{1}{64} \right) \left( \frac{1}{4} \right)^{16n} (e^{5i\pi/8} + e^{-5i\pi/8})
\]

\[
v(m) = \mu_2 \left( \frac{1}{16} \right) \left( \frac{1}{2\sqrt{2}} \right)^{16n} - \mu_3 \left( \frac{1}{32} \right) \left( \frac{3\pi/8}{4\sqrt{2} \mu_3} \right)^{16n}
\]

which will be positive eventually (as \( 1/2\sqrt{2} > 1/4 \)) but negative initially. Again, we can compute \( n_3 \) such that for \( n \in [0, n_3] \) \( v(m) \leq 0 \) while for \( n \in (n_3, \infty) \) \( v(m) > 0. \) Namely, \( n_3 = \left[ \frac{1}{8} \log_2 \left( \frac{\cos(3\pi/8)}{4\sqrt{2} \mu_3} \right) \right]. \) Again, \( n_3 \) can take any value by choosing \( \mu_2 \) and \( \mu_3 \) appropriately.
Finally, for $L^A_{16}$, $m = 16n + 4$ hence

$$v(m) = \mu_1 \left( \frac{1}{16} \right) \left( \frac{1}{2} \right)^{16n} (e^0 + e^0) + \mu_2 \left( \frac{1}{64} \right) \left( \frac{1}{2\sqrt{2}} \right)^{16n} (e^{i\pi} + e^{-i\pi})$$

$$+ \mu_3 \left( \frac{1}{256} \right) \left( \frac{1}{4} \right)^{16n} (e^{i\pi/2} + e^{-i\pi/2})$$

$$v(m) = \mu_1 \left( \frac{1}{8} \right) \left( \frac{1}{2} \right)^{16n} - \mu_2 \left( \frac{1}{32} \right) \left( \frac{1}{2\sqrt{2}} \right)^{16n}$$

(4)

which will be positive eventually (as $1/2 > 1/2\sqrt{2}$) but negative initially. Thus, we have for $n \in [0, n_4]$ $v(m) \leq 0$ while for $n \in (n_4, \infty)$ $v(m) > 0$, where $n_4 = \left\lfloor \frac{\log_2 \left( \frac{\mu_2}{\mu_3} \right)}{8} \right\rfloor$. Again, $n_4$ can take any value by choosing $\mu_1$ and $\mu_2$ appropriately.

Hence for $k = 16$, $L^A_{16} = \{A^{n_2+1}B^w \}$ similarly $L^B_{16} = \{B^{n_3+1}A^w \}$ and $L^C_{16} = \{B^{n_4+1}A^w \}$. Thus for $n_3 < n_2 < n_4$ (which we ensure later by varying $\delta$ over the appropriate $Init$), we obtain $L^A_{2,3,4} = (ABB)^{n_2+1}(AAB)^{n_2-n_3}(BAB)^{n_4-n_2}(BAA)^w$. Now as $n_2, n_3$ and $n_4$ are only in terms of $\mu_1, \mu_2$ and $\mu_3$ we can define

$$g(\mu_1, \mu_2, \mu_3) = 2n_2 - n_3 - n_4$$

(5)

If we ignore floor functions in the definitions of $n_2, n_3, n_4$ we get $g(\mu_1, \mu_2, \mu_3)$ as a constant ($\approx .236$). And introducing 4 floor functions can only change the value by atmost 4. Hence $-5 \leq g(\mu_1, \mu_2, \mu_3) \leq 5$. Substituting in $L^A_{2,3,4}$ we get $L^A_{2,3,4} = (ABB)^{n_2+1}(AAB)^{n_2-n_3+g(\mu_1, \mu_2, \mu_3)}(BAB)^{n_4-n_2}(BAA)^w$.

We consider the initial set of distributions $Init$ to be the line segment $(P1, P2)$ where $P1 = (1, a, a, b, b, c, c)$ and $P2 = (1, 0, 0, b, b, c, c)$ in the eigenvector basis, where $a = -\cos(3\pi/8)$, $b = \frac{1}{2}$, $c = \frac{1}{2\cos(3\pi/8)}$. These values are chosen so that $\mu_0$ dominates over the other terms in the above equation, which ensures that $P1$ and $P2$ correspond valid distributions in the standard basis. Note that the distributions in $Init$ are just convex combinations of distributions at $P1$ and $P2$. Finally, let us now denote $L = L_{Init}(A_1) = \bigcup_{\delta \in Init} L_{2,3,4}(A_1) = \bigcup_{\delta \in Init} L_{2,3,4}$ similarly $L_{16} = \bigcup_{\delta \in Init} L^A_{16}$.

Now, since $n_3$ only depends on $\mu_2$ and $\mu_3$ which are constant for $Init$, we obtain $n_3 = 1$. Further, for all initial distributions from $Init$, we observe that $n_4 - n_2 \in [1, \infty)$. By varying $\delta$ over all $Init$ and substituting $n_4 - n_2 = \ell$, and by equation 5, we have $L_{16} = \{(ABB)^2(AAB)^{\ell+g(\mu_1, \mu_2, \mu_3)}(BAA)^{\ell+g(\mu_1, \mu_2, \mu_3)}(BAA)^w : \ell \geq 1\}$. Finally, we have

**Lemma 16.** $L^A_{2,3,4} \subseteq \{A, B\}^w$ is not regular language.

**Proof.** Let us assume $L^A_{2,3,4}$ is regular then by Myhill-Nerode Theorem we have $L^A_{2,3,4} = \{(AAB)^{\ell+g(\mu_1, \mu_2, \mu_3)}(BAA)^{\ell+g(\mu_1, \mu_2, \mu_3)} : \ell \geq 1\}$ is also regular. Consider the homomorphism $\phi : \{A, B, C\} \to \Sigma^*$ where $\phi(A) = AAB$, $\phi(B) = BAB$ and $\phi(C) = BAA$. As regular languages are closed under inverse homomorphism consider $L^A_{2,3,4}$ under inverse of $\phi$. This gives $L^A_{2,3,4} = \{(A)^{\ell+g(\mu_1, \mu_2, \mu_3)}(C)^{\ell+g(\mu_1, \mu_2, \mu_3)} : \ell \geq 1\}$. As $-5 \leq g(\mu_1, \mu_2, \mu_3) \leq 5$, the difference between number of $A$’s and $B$’s in this language can be atmost 5. We now show this language to be irregular by the pumping lemma:

Let $p$ be the pumping length. Let $w \in L$ be given by $w = (AAB)^p g(\mu_1, \mu_2, \mu_3)(BAA)^p(BAA)^w$. By the pumping lemma, there must be some decomposition $w = xyz$ with $|xy| \leq p$ and $|y| \geq 1$ such that $x^i y z \in L$ for every $i \geq 0$. Using $|xy| \leq p$, we know $y$ only consists of instances of $A$. Moreover, because $|y| \geq 1$, it contains at least one instance of $A$. We now pump $y$ up: $x y^{11} z$ has difference between number of $A$’s and number of $B$’s is more

\section*{Figure 2 Eigenvectors of $M_1$}

than 5. Therefore $xy^{11}z$ is not in $L_{2,3,4}^{n16}$. We have reached a contradiction. Therefore, the assumption that $L_{2,3,4}^{4}$ is regular must be incorrect. Hence $L_{2,3,4}^{16}$ is irregular.

Finally, we have the following lemma which completes the proof of Theorem 10.

\section*{Lemma 17.} For all $k > 4$, if $L_{2,3,4}^k$ is not regular then $L = \mathcal{L}(Init, A_1)$ is not regular.

\section*{Proof.} Contrapositive: If $L$ is regular then so is $L_{2,3,4}^k$. Let the Büchi Automaton of $L$ be $(Q, \Sigma, \Delta, I, F)$. Consider a Büchi Automaton $(Q', \Sigma, \Delta', I', F')$ where $Q' = Q \times \{1, \ldots, k\}$, $\Delta'((q, 1), \epsilon) = \bigcup_i \{(p, 2)|p \in \Delta(q, a_i)\}$ $\Delta'((q, 2), a) = \{(p, 3)|p \in \Delta(q, a)\}$ $\Delta'((q, 3), a) = \{(p, 4)|p \in \Delta(q, a)\}$ $\Delta'((q, 4), a) = \{(p, 5)|p \in \Delta(q, a)\}$ $\Delta'((q, j), \epsilon) = \bigcup_i \{(p, j + 1)|p \in \Delta(q, a_i)\}$ for $j > 4, j < k$ $\Delta'((q, k), \epsilon) = \bigcup_i \{(p, 1)|p \in \Delta(q, a_i)\}$ $I' = \{(s, 1)|s \in I\}$, $F' = \{(s, j)|s \in I\}$ and $0 < j < k$.

This Büchi automaton accepts exactly $L_{2,3,4}^k$ as only $m$th characters (where $m \mod k = 2, 3, 4$) are picked from $L$. Hence if $L_{2,3,4}^k$ is not regular then $L = \mathcal{L}(Init, A_1)$ is also irregular.
