PDE-based Graph Signal Processing for 3D Color Point Clouds: Opportunities for Cultural Heritage.

François Lozes, Abderrahim Elmoataz, Olivier Lézoray

Abstract—With the advance of 3D scanning technology, the cultural heritage community is increasingly interested in 3D scans of cultural objects such as antiques, artifacts and heritage sites. Digitization of these objects is commonly aimed at heritage preservation. Since 3D color scanning has the potential to tackle a variety of traditional documentation challenges, the use of signal processing techniques on such data can be expected to yield new applications that are feasible for the first time with the aid of captured 3D color point clouds. Our contributions are twofold. First, we propose a simple method to solve PDEs (Partial Differential Equations) on point clouds using the framework of PdEs (Partial difference Equations) on graphs. Second, we survey several applications of 3D color point cloud processing on real examples for which signal processing researchers can develop tools that can be valuable for museum specialists. The results of these methods have been reviewed by experts in the arts and found promising.

Index Terms—point cloud, mesh, culture heritage, filtering, interpolation, PDEs on weighted graphs.

I. INTRODUCTION

Historians, archaeologists, and museums curators are interested in the preservation of pieces of art and want to make them available to as wide an audience as possible. While direct encounter with the material pieces of art will always have an essential value for museum specialists, one important concern for museum curators is the preparation of catalogues for the purpose of object identification and examination. Traditionally, museum specialists have used two-dimensional imaging techniques such as hand drawings, photographs, or document scans see [1, 2]. Unfortunately, these standard formats have the limitation of being selective and insufficient to record nuanced information about the complete shape, color and texture of the object. In addition, some objects might undergo important changes over time, and in this case the preservation of the object state (at a given temporal snapshot) is important. These issues can now be addressed by using 3D color scanning which has the ability to record the complete object in great detail. The production of digital three-dimensional copies of pieces of art has therefore gained considerable attention from the cultural heritage community [3]. The recent proliferation

This work was funded under a Ph.D. grant of the regional council of Lower-Normandy.

We thank the Memorial of Caen that allowed us to acquire some WWII objects using our scanner.

Figure 1: The PdEs framework on weighted graphs can be applied to solve PDEs on 3D point clouds.

of commercial three-dimensional digital scanning devices has lead to the establishment of 3D scanning as a practical reality in the field of cultural heritage preservation [4]. The interest is evident: it provides a high precision digital reference of a cultural object, and makes possible mass distribution and consultation.

Most traditional signals processing methods in art investigation, such as filtering, PDE-based processing, and wavelets, are designed for data defined on regular Euclidean grids, see [2, 5]. With 3D color point clouds, the data takes the form of unstructured raw point samples without any attached geometry. Traditional signal processing tools cannot be directly applied on raw 3D color point clouds since there is no structuring information. In addition, it is not desirable to transform point clouds to meshes since this requires sampling points with a loss of accuracy and this is not compatible with the goal of high-fidelity conservation. Therefore it is essential to investigate a framework for the adaptation of signal processing tools for 3D point cloud processing.

Our contributions are twofold. First, we propose a simple method for adapting and solving PDEs on point clouds. This method relies the framework of PdEs on weighted graphs [6] as shown in Figure 1. Second, we survey several applications in 3D color point cloud processing where signal processing tools can be applied to images of interest to art and museum specialists. From a signal processing point of view, most of these problems can be formulated as inverse problems for graph signals [7] (signals living on graphs representing 3D color point clouds as in Figure 1).

The paper is organized as follows. Section II explains how three dimensional images of historic or art items can be acquired. Section III presents the method used to construct a weighted graph from a point cloud. Section IV shows that 3D color point clouds can be considered as a new type of data called *graph signals* [7] and how the associated emerging field of graph signal processing [7] allows such data to be processed in a unified framework. Finally, section V provides experimental results.

II. 3D COLOR POINT CLOUDS

This section details how three dimensional images of historic or art items can be acquired. We first provide a review of the benefits and disadvantages of each of the current technologies. In cultural heritage, two main approaches are used to digitize a 3D object.

The first approach is photogrammetry. This is an image-based modeling technique where multiple photos are taken to retrieve 3D data coordinates. Photogrammetry requires only cameras, and is the least expensive approach. However, it works only with small objects with regular geometric shapes. The second approach is laser scanning. In this approach, the scanner acquires many 3D points of the object to digitize. The precision is much better but both the cost and the acquisition time are greater. In this paper, we focus on this latter type of 3D raw point clouds.

Figure 2 shows the acquisition of several WWII items, acquired by a Konica Minolta VIVID-9i non-contact 3D laser scanner, with a lens of $f = 25$ mm focal length at a distance of 0.6 m. According to the specification of the scanner, this corresponds to an accuracy of digitizing of ± 0.05 mm.

A point cloud is composed of raw data $\mathcal{D} = \{d_1, \dots, d_n\}$. One associates to each $d_i \in \mathcal{D}$ a 3D coordinate vector $\mathcal{P} = \{p_1, \dots, p_n\}$, with $p_i(p_i^x, p_i^y, p_i^z)^T \in \mathbb{R}^3$, and a color vector $\mathcal{C} = \{c_1, \dots, c_n\}$, with $c_i(c_i^R, c_i^G, c_i^B)^T \in \mathbb{R}^3$. We define for a given point cloud a function $f^* : \mathcal{D} \rightarrow \mathbb{R}^3$, which is either $f^* : \mathcal{D} \rightarrow \mathcal{P}$ or $f^* : \mathcal{D} \rightarrow \mathcal{C}$. The function f^* is difficult to process and to analyze with classical signal processing techniques because the underlying point cloud lacks of any topological structure. Therefore classical 2D signal processing techniques cannot be considered and new dedicated graph signal processing techniques are needed.

III. GRAPH CONSTRUCTION FROM POINT CLOUDS

The proposed approach to process point clouds, starts by creating a weighted graph from a given point cloud. This section shows how to build such a graph. This latter method is composed of two parts: first the topology of the graph is defined, and then the edges of the graph are weighted.

A. Graph construction

This subsection discusses how to build a weighted graph from a 3D point clouds. The creation of a graph requires several steps. First, vertices are created from the raw data. Second, the vertices are connected with edges to build a proximity graph based on geometrical structure of the point cloud. Third, weights associated with each edge are calculated. Weights of

Figure 2: Some objects of the WWII acquired with our 3D scanner at the Mémorial of Caen. From left to right, respectively: a lamp, a canteen and a part of a destroyed church.

edges are deduced from values associated to vertices (the graph signal) and patches can be used to compute a better similarity value that takes account of local neighborhood similarities.

Graph creation from point clouds is challenging. Indeed, the structuring information is lacking and the data is not naturally organized in a manifold. Therefore, the set of edges cannot be easily determined. Given a point cloud P with associated coordinates $\{\mathbf{p}_1, \dots, \mathbf{p}_n\} \in \mathbb{R}^3$, there are many ways of associating a graph to such a data set. Since point clouds data exhibit a geometrical structure, proximity graphs are preferable: if two data points satisfy certain geometric requirements, the corresponding vertices in the graph are connected by an edge. To each raw data point $d_i \in \mathcal{D}$, one associates a vertex of a proximity graph $\mathcal{G}$ to define a set of vertices $\mathcal{V} = \{v_1, v_2, \dots, v_n\}$. Then, determining the edge set $\mathcal{E}$ of the proximity graph $\mathcal{G}$ requires defining the neighbors of each vertex v_i according to its embedding $\mathbf{p}_i$ using the Euclidean distance. Among many possible choices, we choose to consider the symmetric k Nearest Neighbor Graph (k -NNG). An undirected edge (v_i, v_j) is added between two vertices v_i and v_j if the distance between $\mathbf{p}_i$ and $\mathbf{p}_j$ is among the k smallest distances from either $\mathbf{p}_i$ or $\mathbf{p}_j$ to all the other data points. The construction of such a graph being computationally expensive for large point clouds, a k D-tree is used [8] to speed-up the k nearest neighbor search.

B. Graph Weights

Once the graph has been created, it has to be weighted. If one wants to ignore the vertex similarities, the weight function w can be set to $w(v_i, v_j) = 1, \forall (v_i, v_j) \in \mathcal{E}$. To account for the similarities between the graph signals associated with the vertices, it is possible to use similarity functions based on distances to define the edge weights. Given an initial function $\mathbf{f}^0 : \mathcal{V} \rightarrow \mathbb{R}^m$, computing distances between vertices consists of comparing their features (as a function of $\mathbf{f}^0$). To this end, each vertex v_i is associated with a feature vector $\mathcal{P}(v_i) \in \mathbb{R}^q$. From this, a usual similarity measure is provided by the Gaussian kernel:

$$w(v_i, v_j) = \exp\left(-\frac{\|\mathcal{P}(v_i) - \mathcal{P}(v_j)\|_2^2}{\sigma^2}\right). \quad (1)$$

Traditionally, one has simply $\mathcal{P}(v_i) = \mathbf{f}^0(v_i)$. However, in image processing an important feature vector is provided by image patches [9]. In [10], we have proposed a new definition of patches that can be used with any graph representation associated to meshes or point clouds. We detail the latter.

Figure 3: Figure (a) shows the interpolation of the content of the patch. l is the patch length. $\mathbf{o}_0(v_i)$ and $\mathbf{o}_1(v_i)$ are the orientation of the patch $\mathcal{P}(v_i)$ at a point $\mathbf{p}_i$. Elements marked by a “x” symbol correspond to the projected neighbors $\mathbf{p}'_i$ of the point $\mathbf{p}_i$ on the patch. These projections are used to deduce values of each patch cell (a “o” symbol) by a weighted average of the associated graph signal values. Figure (b) shows a point cloud with a selected vertex (in white), and the patch descriptor of that vertex. Figure (c) shows a point cloud colored by the patch-based distance between all points and a given selected one, from most similar (in red) to least similar (in blue).

1) *Patch Definition:* Around each vertex we build a two-dimensional grid (the patch) describing the neighborhood. This grid is defined on the tangent plane of the point (i.e., the vertex). Then the patch is oriented and finally the patch is filled-in with a weighted average of the graph-signal values in the local neighborhood. We detail these two steps below.

Orientation The first step consists of estimating the orientation of each patch. The algorithm first deduces a tangent vector $\mathbf{t}_1(v_i)$ from the normal vector $\mathbf{n}(v_i)$. We use a local PCA on the coordinates p_i to estimate this normal vector: $\mathbf{t}_0(v_i) = \mathbf{n}(v_i)$. Let $\mathbf{x}, \mathbf{y}, \mathbf{z}$ be the three axes of a 3D space, the first tangent vector $\mathbf{t}_1(v_i)$ is computed with:

$$\begin{cases} \mathbf{t}_1(v_i) = \mathbf{z} \times \mathbf{t}_0(v_i) & \text{if } |\mathbf{z} \cdot \mathbf{t}_0(v_i)| \neq 1 \\ \mathbf{t}_1(v_i) = \mathbf{x} \times \mathbf{t}_0(v_i) & \text{otherwise,} \end{cases} \quad (2)$$

with $\times$ the cross product, and $\cdot$ the dot product. The condition on the first line of (2) checks if the $\mathbf{t}_1$ and $\mathbf{z}$ axis vector are collinear. If they are not collinear, $\mathbf{t}_1$ is calculated from the $\mathbf{z}$ axis, otherwise the $\mathbf{x}$ axis is used. Then a bitangent vector

$\mathbf{t}_2(v_i)$ is computed by $\mathbf{t}_2(v_i) = \mathbf{t}_0(v_i) \times \mathbf{t}_1(v_i)$. The orientation vectors $\mathbf{o}_0(v_i), \mathbf{o}_1(v_i), \mathbf{o}_2(v_i)$ are then respectively assigned to $\mathbf{t}_1(v_i), \mathbf{t}_2(v_i), \mathbf{t}_0(v_i)$.

Patch construction The second step consists of constructing the patches. Given a point $\mathbf{p}_i$, a patch is defined for this point by constructing a square grid around $\mathbf{p}_i$ on its tangent plane in the orientation of the patch defined by $(\mathbf{o}_0, \mathbf{o}_1)$. We fix the patch length l manually. Let n be the number of cells on a row of the patch. A square lattice of n^2 cells is constructed around $\mathbf{p}_i$ with respect to the basis obtained from the orientation computation. Each cell has a side length of l/n . A local graph is then considered that connects the vertex v_i to all the vertices v_j contained in a sphere of diameter $l\sqrt{2}$. Then, all the neighbors v_j of v_i are projected on the tangent plane of $\mathbf{p}_i$ giving rise to projected points $\mathbf{p}'_j$. To fill the patch with values, these projected points $\mathbf{p}'_j$ are associated with the cells with the closest center. The value of the cell is then deduced from a weighted average of the values $f^0(v_j)$ associated with the vertices v_j that were projected onto the patch cell. This value is a spectral value (the point’s colors). The set of values inside the patch of the vertex v_i are denoted $\mathcal{P}(v_i)$. Let $C_k(v_i)$ denote the k th cell of the constructed patch around v_i with $k \in [1, n^2]$. With the proposed patch construction process, define the set $V_k(v_i) = \{v_j \mid \mathbf{p}'_j \in C_k(v_i)\}$ as the set of vertices v_j that were associated with the k th patch cell of v_i . Then, the patch vector is defined as :

$$\mathcal{P}(v_i) = \left(\frac{\sum_{v_j \in V_k(v_i)} w_p(\mathbf{c}_k, \mathbf{p}_j) f^0(v_j)}{\sum_{v_j \in V_k(v_i)} w_p(\mathbf{c}_k, \mathbf{p}_j)} \right)_{k \in [1, n^2]}^T, \quad (3)$$

with $w_p(\mathbf{c}_k, \mathbf{p}_j) = \exp(-\frac{\|\mathbf{c}_k - \mathbf{p}'_j\|^2}{\sigma^2})$ where the $\mathbf{c}_k$ are the coordinate vectors of the k th patch cell center. This weighting takes into account the distribution of the points in the cells of the patch by computing their mean feature vector. Figure 3(a) summarizes the method of patch construction. Figures 3(b) and 3(c) show that points with similar geometric configurations are close with respect to the patch distance. With the following (parameters are respectively $\sigma = 0.3$ and $n = 5$).

IV. GRAPH SIGNAL PROCESSING

This section provides the mathematical definitions needed to understand the construction of weighted graphs from point clouds.

A. PdEs on weighted graphs

The definitions presented here provide the basis on which it is possible to translate PDEs on graphs into PdEs on graphs. Most of these definitions are borrowed from [6].

1) *Definitions:* A weighted graph $\mathcal{G} = (\mathcal{V}, \mathcal{E}, w)$ consists of a finite set $\mathcal{V} = \{v_1, \dots, v_N\}$ of N vertices and a finite set $\mathcal{E} \subset \mathcal{V} \times \mathcal{V}$ of weighted edges. Assume $\mathcal{G}$ to be undirected, with no self-loops and no multiple edges. Let (v_i, v_j) be the edge of $\mathcal{E}$ that connects two vertices v_i and v_j of $\mathcal{V}$. Its weight, denoted by $w(v_i, v_j)$, represents the similarity between its vertices. Similarities are usually computed by using a positive symmetric function $w : \mathcal{V} \times \mathcal{V} \rightarrow \mathbb{R}^+$ satisfying $w(v_i, v_j) = 0$

if $(v_i, v_j) \notin \mathcal{E}$. The notation $v_i \sim v_j$ is also used to denote two adjacent vertices. The degree of a vertex v_i is defined as $\delta_w(v_i) = \sum_{v_j \sim v_i} w(v_i, v_j)$. Let $\mathcal{H}(\mathcal{V})$ be the Hilbert space of real-valued functions defined on the vertices of a graph. A function $f \in \mathcal{H}(\mathcal{V})$ assigns a real value $f(v_i)$ to each vertex $v_i \in \mathcal{V}$. We define the internal border of a set $A \subset \mathcal{V}$ as $\partial^- A = \{v_i \in A | \exists v_j \sim v_i, v_j \in \partial A\}$.

Similarly, we define the space $\mathcal{H}(\mathcal{E})$ of functions which are defined on the set $\mathcal{E}$ of edges. Given a function $f : \mathcal{V} \rightarrow \mathbb{R}$, its ℓ_p and ℓ_∞ norms are given by

$$\|f\|_p = \left(\sum_{v_i \in \mathcal{V}} |f(v_i)|^p \right)^{1/p}, \quad \text{with } 1 \leq p < \infty, \quad (4)$$

$$\|f\|_\infty = \max_{v_i \in \mathcal{V}} |f(v_i)|, \quad \text{for } p = \infty. \quad (5)$$

2) *Difference operators on weighted graphs:* Let $\mathcal{G} = (\mathcal{V}, \mathcal{E}, w)$ be a weighted graph and $w : \mathcal{V} \times \mathcal{V} \rightarrow \mathbb{R}^+$ a weight function that depends on the interactions between the vertices. The *difference operator* [6], denoted $d_w : \mathcal{H}(\mathcal{V}) \rightarrow \mathcal{H}(\mathcal{E})$, is defined for all $f \in \mathcal{H}(\mathcal{V})$ and $(v_i, v_j) \in \mathcal{E}$ by

$$(d_w f)(v_i, v_j) = \sqrt{w(v_i, v_j)} (f(v_j) - f(v_i)). \quad (6)$$

The *weighted gradient operator* of a function $f \in \mathcal{H}(\mathcal{V})$, at a vertex $v_i \in \mathcal{V}$, is the vector defined by

$$(\nabla_w f)(v_i) = ((d_w f)(v_i, v_j))_{v_j \in \mathcal{V}}^T. \quad (7)$$

The ℓ_p norm of this vector is defined, for $p \geq 1$, as

$$\|(\nabla_w f)(v_i)\|_p = \left(\sum_{v_j \sim v_i} w(v_i, v_j)^{p/2} |f(v_j) - f(v_i)|^p \right)^{1/p}. \quad (8)$$

The external and internal *morphological directional difference operators* are defined as in [11] to be $((d_w f)(v_i, v_j))^\pm$, with $(x)^+ = \max(x, 0)$ and $(x)^- = -\min(x, 0) = \max(-x, 0) = (-x)^+$. The corresponding *discrete upwind weighted gradients* are

$$(\nabla_w^\pm f)(v_i) = \left(((d_w f)(v_i, v_j))^\pm \right)_{v_j \in \mathcal{V}}^T. \quad (9)$$

The ℓ_p and the ℓ_∞ norms of these gradients are

$$\|(\nabla_w^\pm f)(v_i)\|_p = \left[\sum_{v_j \sim v_i} w(v_i, v_j)^{\frac{p}{2}} \left((f(v_j) - f(v_i))^\pm \right)^p \right]^{\frac{1}{p}}, \quad (10)$$

$$\|(\nabla_w^\pm f)(v_i)\|_\infty = \max_{v_j \sim v_i} \sqrt{w(v_i, v_j)} (f(v_j) - f(v_i))^\pm. \quad (11)$$

3) *p-Laplace operators on weighted graphs:* The *isotropic weighted p-Laplace operator*, with $p \in [1, +\infty[$, at a vertex $v_i \in \mathcal{V}$ is defined on $\mathcal{H}(\mathcal{V})$ by [6] as

$$(\Delta_{w,p}^i f)(v_i) = \sum_{v_j \sim v_i} \psi_{w,p}^i(v_i, v_j) (f(v_i) - f(v_j)), \quad (12)$$

Figure 4: Filtering of a noisy Maya wall with preservation of edges, (a) noisy point cloud, (b) denoised point cloud.

where

$$\psi_{w,p}^i(v_i, v_j) = \frac{1}{2} w(v_i, v_j) (\|\nabla_w f(v_i)\|_2^{p-2} + \|\nabla_w f(v_j)\|_2^{p-2}). \quad (13)$$

The ∞ -Laplacian is defined by [12] as

$$(\Delta_{w,\infty} f)(v_i) = \frac{1}{2} [\|(\nabla_w^+ f)(v_i)\|_\infty - \|(\nabla_w^- f)(v_i)\|_\infty]. \quad (14)$$

From the definitions of these discrete difference operators on graphs, we are now in position to translate any PDEs that involves gradient, p -Laplacian or ∞ -Laplacian in their continuous formulation onto Euclidean domains. In the sequel, we will consider directly the discrete formulation on graphs, see [6] for further details.

B. Regularization on graphs

This subsection presents some PDEs on graphs and shows a methodology to regularize the functions defined on the vertices of graphs. Let $f^0 \in \mathcal{H}(\mathcal{V})$ be a given function defined on the vertices of a weighted graph $G = (\mathcal{V}, \mathcal{E}, w)$. In a given context this function represents an observation of a clean function $h \in \mathcal{H}(\mathcal{V})$ corrupted by an additive noise $n \in \mathcal{H}(\mathcal{V})$ such that $f^0 = h + n$. Regularizing functions on graphs using either isotropic or anisotropic p -Laplacian, was proposed in [6, 13]. Recently, a new family of p -Laplace operators based on a divergence formulation, that unifies both the isotropic and anisotropic p -Laplacian on graphs, has been proposed in [10].

To recover the uncorrupted function h , the processing task is to remove the noise n from f^0 . A commonly used method is to seek a function $f \in \mathcal{H}(\mathcal{V})$, which is regular enough on G , and also close enough to f^0 . This can be formalized by the minimization of an energy functional, that involves a regularization term (or penalty term) plus an approximation one (or fitting term). This paper considers the following model:

$$h \approx \arg \min_{f: \mathcal{V} \rightarrow \mathbb{R}} J_{w,p}^\phi(f) + \frac{\lambda}{2} \|f - f^0\|_2^2 \quad (15)$$

$$\text{where } J_{w,p}^\phi(f) = \sum_{v_i \in \mathcal{V}} \phi(\|(\nabla_w f)(v_i)\|_p) \quad (16)$$

is a gradient-based functional, and $\lambda \in \mathbb{R}$ is a regularization parameter, called the Lagrange multiplier, that controls the trade-off between the penalty term and the fitting term. The function $\phi(\cdot)$ is a positive convex function that penalizes large variations of f in the neighborhood of each vertex.

To solve (16), we consider the Euler-Lagrange equations

$$\frac{\partial J_{w,p}^\phi(f)}{\partial f(v_i)} + \lambda(f(v_i) - f^0(v_i)) = 0, \forall v_i \in \mathcal{V}, \quad (17)$$

where the first term denotes the variation of (16) with respect to f at a vertex v_i .

In [10], we have proven that the solution of (17) can be obtained with the following iterative algorithm

$$f^{n+1}(v_i) = \frac{\lambda f^0(v_i) + \sum_{v_j \sim v_i} \beta_{v_i, v_j}^{\phi, p, f} f^n(v_j)}{\lambda + \sum_{v_j \sim v_i} \beta_{v_i, v_j}^{\phi, p, f}}. \quad (18)$$

with

$$\beta_{v_i, v_j}^{\phi, p, f} = \alpha_{v_i, v_j}^{\phi, p, f} |f(v_j) - f(v_i)|^{p-2} \quad (19)$$

and

$$\alpha_{v_i, v_j}^{\phi, p, f} = w(v_i, v_j)^{p/2} \left(\frac{\phi'(\|(\nabla_w f)(v_i)\|_p)}{\|(\nabla_w f)(v_i)\|_p^{p-1}} + \frac{\phi'(\|(\nabla_w f)(v_j)\|_p)}{\|(\nabla_w f)(v_j)\|_p^{p-1}} \right). \quad (20)$$

Figure 4 shows such color filtering of a given 3D colored point cloud (obtained from a laser scan of a Maya temple wall).

V. APPLICATIONS

This section gives an overview of 3D color Point Cloud applications. We illustrate the abilities of the proposed methods and algorithms for signal processing on point clouds¹. The typical graph signals are point (resp. vertices) coordinates or colors. Given a weighted graph $\mathcal{G} = (\mathcal{V}, \mathcal{E}, w)$ associated to a point cloud, consider an initial graph signal $\mathbf{f}^0 : \mathcal{V} \rightarrow \mathbb{R}^m$ with $m = 3$. This signal will be either the vertices' coordinates, in which that case $\mathbf{f}^0(v_i) = \mathbf{p}_i$, or the vertices' colors, in which that case $\mathbf{f}^0(v_i) = (f^R(v_i), f^G(v_i), f^B(v_i))^T$ where $f^X(v_i)$ denotes the X color component of the color at the vertex v_i .

The approach we developed can be interesting within a cultural heritage documentation, analysis and dissemination perspective². First of all, the idea to introduce a method for structuring color / texture information within a point-based 3D representation is particularly relevant within the 3D digitization and documentation purposes. Points clouds (especially if enriched by color information) include the essential geometric information useful for several applications scenarios related to the heritage artifacts analysis (measurement, visualisation, semantic annotation, etc...). The point clouds processing methods we suggest (colorization, filtering and simplification, inpainting of missing data and segmentation) can find several effective applications within the digital driven process for documenting heritage buildings, archaeological sites and museums objects.

A. Colorization

Colorization is the process of adding colors on an uncolored object. Let $\mathbf{f}^0 : \mathcal{V} \rightarrow \mathcal{C}$ be a function that assigns colors to vertices. Let $A \subset \mathcal{V}$ be the subset of vertices with unknown

¹All the 3D point clouds we used are available at <https://lozes.users.greyc.fr/>

²According to the evaluation done by the art expert Livio De Luca (see section VII).

Figure 5: Colorization of the bishop castle (approx. 1.5 million points) and a Bas-relief (with 506k points).

colors and ∂A the subset of vertices with known values. The purpose of interpolation is to find a function $\hat{f}$ approximating f^0 in $\mathcal{V}$ minimizing the following isotropic total variation energy for $v_i \in A$:

$$\min_{f \in H(\mathcal{V})} \left\{ R_{w,p}(f) = \sum_{v_i \in A} \|\nabla_w f(v_i)\|_p^p \right\}, \quad (21)$$

with $f(v_i) = f^0(v_i)$, for $v_i \in \partial A$. This can again be solved using the Euler-Lagrange equations

$$\begin{cases} (\Delta_{w,p}^i f)(v_i) = 0 & \forall v_i \in A, \\ f(v_i) = f^0(v_i) & \forall v_i \in \partial A. \end{cases} \quad (22)$$

The solution of (22) can be obtained with the iterative algorithm in (18) with $\lambda = 0, \forall v_i \in \partial^- A$. The similarity function $w : \mathcal{V} \times \mathcal{V} \rightarrow \mathbb{R}$ is computed from the comparison of patches of a geometric feature. This geometric feature is computed from the degree at a vertex using local height weights. These later weights are obtained from the similarity of height patches. Since the colorization starts from initial color annotations, not all the points are considered simultaneously. The colorization starts from the points that are neighbors to the annotated colors and the set of points to be colorized grows as the algorithm iterates. The colorization process stops when the set of vertices to colorize is empty and has converged to a stable solution. The use of adaptive geometrical weights relying on a geometric feature maps patches enables to better take into account the geometry of the point cloud during the color diffusion and

Figure 6: Colorization of some cultural heritage statues (point clouds sizes, from left to right: 253k, 254k, 791k points).

blending.

Figure 6 shows the colorization on some uncolored statues. Figure 5 shows the colorization of the bishop castle and of a Bas-relief. Both cases show that the colorization allows restoration of colors not captured by the 3D scanner (the bishop castle case), but also allows placement of colors on an initially uncolored object (statues cases) for a more realistic rendering.

B. Filtering and simplification

Modern 3D scanners can generate large point clouds with several million or billion points. The processing of such data is difficult. Instead of downscaling the point clouds and losing details, we propose a way to remove fine details without modify the appearance of the point cloud. It can be interesting to filter and simplify complex and redundant point clouds for web publication purposes.

Let $\mathbf{f}^0 : \mathcal{V} \rightarrow \mathcal{P}$ be the vertices coordinates. The iterative algorithm of (18) allows filtering the geometry of 3D objects using $\lambda = 0$. Figure 7 shows the simplification of a point cloud of the Saint Eligius statue with a reduction in the number of points by 77.6% using parameters $p = 0.1$ and $\phi(s) = s^p$. With such a simplified point cloud, the processing of any data on this point cloud, like colors, becomes computationally feasible. Indeed, reducing the quantity of data to process makes algorithms and renderings faster. Lastly, the simplification could be leveraged in a meshing process by producing more regular polygons.

C. Inpainting of missing data

Inpainting consists of constructing new values for missing data in coherence with a set of known data. This can be the reconstruction of deteriorated parts of a 3D object represented as a point cloud. This can be of interest for extending color information to missing parts (e.g., for virtual restoration purposes). Recent inpainting work tends to unify local and nonlocal approaches under a variational formulation (see [14] and references therein for more details). We consider that data are defined on a general domain represented on a graph $\mathcal{G} = (\mathcal{V}, \mathcal{E}, w)$. Let $\mathbf{f}^0 : \mathcal{V} \rightarrow \mathcal{C}$ be a function that assigns

Figure 7: Simplification of a point cloud of the Saint Eligius statue after 10k iterations. (a) original point cloud (201k points) and (b) point cloud simplified (45k points).

colors to vertices. Let $\mathcal{A} \subset \mathcal{V}$ be the subset of vertices with unknown values and $\partial\mathcal{A}$ the subset of vertices with known values. The purpose of the interpolation is to find a function $\hat{f}$ approximating f^0 in $\mathcal{V}$ and that corresponds to solving

$$\begin{cases} (\Delta_{w,\infty} f)(v_i) = 0 & \forall v_i \in \mathcal{A}, \\ f(v_i) = f^0(v_i) & \forall v_i \in \partial\mathcal{A}. \end{cases} \quad (23)$$

The infinity Laplacian is used here for interpolation since it provides better inpainting results than the isotropic p -Laplacian interpolation (see [15]). Works in [10] have shown that this interpolation problem has a unique solution that can be obtained using the iterative algorithm presented in [12]. At the end of each iteration the set $\partial\mathcal{A}$ is updated by $\partial\mathcal{A}^{(n+1)} = \partial\mathcal{A}^{(n)} \cup \partial^-\mathcal{A}^{(n)}$ and $\partial^-\mathcal{A}^{(n+1)}$ is updated from $\partial\mathcal{A}^{(n+1)}$. The algorithm stops when the set of vertices to inpaint is empty. Figure 8 shows the restoration of a broken vase. The geometric part is corrected first, then the hole is filled; finally, the color is inpainted. One major objective of the cultural heritage is the preservation of an object. This inpainting algorithm provides a plausible virtual reconstruction of the original state of an object. The algorithm can also be used to remove and subvert parts of a damaged object, as in Figure 9.

Figure 8: Restoration pipeline of a vase. The geometric part is first filled, then the missing color is inpainted.

Figure 9: Inpainting of a part of a damaged wall.

D. Segmentation

Segmentation is the process of partitioning a 3D object into multiple regions. Let $f : \mathcal{V} \rightarrow \mathbb{R}$ be the function on a graph $\mathcal{G}(\mathcal{V}, \mathcal{E}, w)$ to segment. The segmentation problem can be formulated as a PDE to be solved on weighted graphs. This latter formulation is based on front propagation using the eikonal equation to compute general distances on graphs. Let $L = \{l_1, \dots, l_n\}$ be the set of labels and let $S^0 = S_1^0 \cup \dots \cup S_n^0$ be the corresponding set of labeled vertices. The goal of label propagation is to label each vertex $u \in \mathcal{V}$ under the condition that u is a neighbor of S_i^0 . Such a label propagation can be formulated as solving the eikonal equation on a graph $\mathcal{G}$ as

$$\begin{cases} \|(\nabla_w^- \phi)(v_i, t)\|_p = P_{l_i}(x) & v_i \in \mathcal{V} \\ f(v_i) = \phi(v_i) & x \in \gamma \subset \mathcal{V} \end{cases} \quad (24)$$

where $F_{l_i} : \mathcal{V} \rightarrow \mathbb{R}^3$ is a speed function, $P_{l_i}(v_i) = \frac{1}{F_{l_i}(v_i)}$, and $\phi : \mathcal{V} \rightarrow \mathbb{R}$ represent the set of initials labels. The resolution of the eikonal equation (24) on a weighted graph has been investigated in [16].

To segment a mesh or a point cloud according to the vertices colors, compute the similarity function $w : \mathcal{V} \times \mathcal{V} \rightarrow \mathbb{R}^+$ by taking into account the colorimetric distance as $w = e^{-\|f^0(v_i) - f^0(v_j)\|/\sigma^2}$, where $f^0 : \mathcal{V} \rightarrow \mathcal{C}$ are the colors associated at the node $v_i \in \mathcal{V}$. The function $\phi : \mathcal{V} \rightarrow \mathbb{R}$ associates an initial label to each vertex v_i . The parameters

Figure 10: Segmentation of vase by resolving the eikonal equation on graphs (770k points for the left vase, and 200k points for the right vase).

are set as follows: $p = 2, F_{l_i}(v_i) = 1, \forall v_i \in \mathcal{V}$. Figure 10 shows some segmentation results on point clouds after the resolution of the eikonal equation. Segmentation results are 3D subsets of the original points clouds. These subsets can then be processed by applying the previous graph signal techniques such as filtering, simplification, inpainting, and colorization.

VI. CONCLUSION

This paper has proposed an approach for the processing of functions on point clouds represented as graphs. We have shown how to translate PDEs using the framework of PdEs. The approach allows processing of signal data on point clouds (e.g., spectral data, colors, coordinates, and curvatures). We have applied this approach for cultural heritage purposes on examples aimed at restoration, denoising, hole-filling, inpainting, object extraction and object colorization. The results demonstrate the many potentials of the point cloud approach to the processing of cultural heritage 3D scanned objects.

VII. ACKNOWLEDGMENTS

Livio De Luca is director of the MAP (Models and simulations for architecture and cultural heritage) laboratory, a

French research unit of the CNRS (National Centre for Scientific Research) and the Ministry of Culture and Communication working on the application of informatics technologies for the study of architecture considered in its heritage, constructive, urban and landscape dimensions. He has evaluated the potential applications of these methods in section V and we thank him for his evaluation.

Abderrahim Elmoataz is a full-time Professor of computer science in the Computer Science Department, Universit de Caen Basse-Normandie, France. His research concerns PDEs on 3D surfaces and points clouds, PDEs on graphs of arbitrary topology with applications in image processing, machine learning.

Franois Lozes received his Ph.D in computer science at the Universit de Caen Basse-Normandie, France. His research mainly concerns the analysis of data on 3D meshes and 3D point clouds using graph signal processing.

Olivier Lzoray received the M.Sc. and Doctoral degrees in computer science from the Universit de Caen Basse-Normandie, France, in 1996 and 2000, respectively. From 1999 to 2000, he was an Assistant Professor with the Computer Science Department, Universit de Caen Basse-Normandie. From 2000 to 2009, he was an Associate Professor Communications, Networks and Services Department, Cherbourg Institute of Technology. Since 2010, he has been a Full Professor at the Cherbourg Institute of Technology. His research concerns color image segmentation and filtering (graph-based variational and morphological methods) and machine learning techniques for image mining (neural networks and support vector machines).
