ABSTRACT

In multimodal human-robot interaction (HRI), the process of communication can be established through verbal, non-verbal, and/or para-verbal cues. The linguistic literature [3] shows that para-verbal and non-verbal communications are naturally synchronized. This research focuses on the relation between non-verbal and para-verbal communication by mapping prosody cues to the corresponding arm gestures. Our approach uses the coupled hidden Markov models (CHMMs), which could be seen as a collection of HMMs, one for the prosodic characteristics' stream and six HMMs for the arm movements' stream [4] [1].

Categories and Subject Descriptors

I.2.9 [Computing Methodologies]: Artificial Intelligence—Robotics

General Terms

Experimentation

1. INTRODUCTION

The important role of robots in our daily life shows the importance of making robots capable of generating intuitive multimodal communication with people under different interactional contexts. This research tries to understand the natural communication strategies of arm gestures that humans use in their daily interaction in order to transfer them to the robots. The database used in this research is the Stanford database available online [5] which is composed of many avatar videos. The data is acquired from human individuals using the PhaseSpace motion capture system and processed with the MotionBuilder system, which provides an approximation of the Euler rotations of the arms' joints.

2. TEMPORAL SEGMENTATION

2.1 Speech

Speech is analyzed in terms of the intensity and pitch curves of the voice signal. The inflection points (i.e., zeros crossing points of the rate of change of the curve) of the pitch and intensity curves, and the separating points between the voiced and the unvoiced parts of the voice signal are detected

Trajectory Class	Trajectory State
1	Pitch ↑ & Intensity ↑
2	Pitch ↑ & Intensity ↓
3	Pitch ↓ & Intensity ↑
4	Pitch ↓ & Intensity ↓
5	Unvoiced segment

Table 1: Voice Signal Segmentation Labels

[1]. The trajectories between the detected points in the pitch and intensity curves are then labeled according to the behavior of these trajectories together (see Table 1). Speech signal is segmented into syllables constituting the states of the HMM of the voice stream. The authors in [2] defined the average duration of a syllable as 200ms and this duration can increase or decrease according to the nature of the syllable as being short or long. Practical tests proved that within a syllable of duration varying from 180ms to 220ms, the average number of trajectory classes in its corresponding pitch and intensity curves is around 5, therefore each 5 labels of the signal constitute a state in the HMM of the voice stream.

2.2 Arm Gestures

Arm gestures are characterized in terms of Euler angles of the six articulations (Elbow, Shoulder, and Wrist) of the two arms. Due to the mechanical limitations of the test platform (Nao robot), Euler rotations of the articulations are limited to be: Pitch and Roll - Shoulder; Yaw and Roll - Elbow; and Yaw - Wrist. Roll, Pitch, and Yaw rotations' data indicated in the database are segmented similarly to the voice signal by comparing the trajectories of the relevant Euler curves of each articulation and giving a label according to the behavior of these trajectories together (see Table 2). However, for the wrist articulation, we used the following rule: if the rate of change of the specific trajectory of the yaw curve is increasing, it takes label 1; if it is decreasing, it takes labels 2; or it takes label 3 for no change. Arms articulations are modeled in terms of six independent HMMs that construct together with the HMM of the voice stream the entire CHMM used for mapping the speech to generated mechanical rotations in each articulation in the arms (fig 1)[4]. Each state in the HMMs modeling arm's articulations presents a complete performed gesture, which is presented by 4 labels of the obtained trajectory classes of each articulation.

Trajectory Class	Trajectory State	
	Shoulder	Elbow
1	Pitch $\uparrow$ & Roll $\uparrow$	Yaw $\uparrow$ & Roll $\uparrow$
2	Pitch $\uparrow$ & Roll $\downarrow$	Yaw $\downarrow$ & Roll $\uparrow$
3	Pitch $\downarrow$ & Roll $\uparrow$	Yaw $\uparrow$ & Roll $\downarrow$
4	Pitch $\downarrow$ & Roll $\downarrow$	Yaw $\downarrow$ & Roll $\downarrow$
5	No Change	No Change

3. SYNTHESIZED GESTURES

The synthesized Euler angles of each articulation are compared to the original Euler angles in terms of the similarity between the trajectory classes (see Table 3). However, during human-human interaction, the generated arm gestures differ from one person to another in terms of the direction and the amplitude of the performed gesture. Therefore, the obtained scores of similarity between the original and synthesized trajectories could be considered as reasonable results (see Figure 2 and 3) because this research focuses on automatic robot arm gestures generation based only on human user prosody.

4. CONCLUSIONS

This research focuses on synthesizing robotic arm gestures based on human user speech characteristics (e.g., pitch and intensity of the signal). Our mapping system is based on the Coupled Hidden Markov Model (CHMM) that tries to find a coupling joint between the audio and gesture sequences. The obtained scores of similarity between the trajectories of the

Articulation	Similarity Scores between Trajectory Classes
Left Shoulder	47%
Left Elbow	55%
Left Wrist	57%
Right Shoulder	52%
Right Elbow	59%
Right Wrist	61%

Figure 3: Original and Synthesized pitch curves for the left shoulder articulation

synthesized and the original Euler angles are in the range of 55%. Moreover, the synthesized gestures are similar to the real gestures and therefore still relevant to the interaction context and capable of conveying a similar message meaning to the message transmitted by the original gestures.
