Introduction

- Natural attenuation is often presented by polluted land owners as an ideal remediation technique for derelict and polluted lands combining revegetation and minimal management and cost.
- But authorities remain skeptic, regulations mostly ignoring this approach.
- Indeed, natural attenuation often sounds to them as "do nothing; nature will take rid of the problem".

Introduction

 This attitude comes from both the lack of studies to really assess the efficiency and threats of this practice but also from its apparent absence of cost for polluters that could seem immoral and against public expectations.

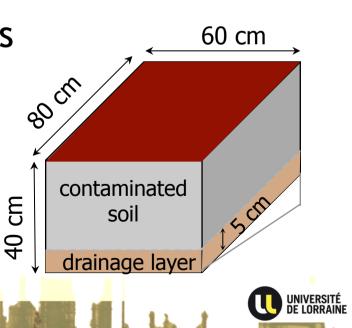

Introduction

- The present work proposes a long term evaluation of natural attenuation for management of PAH contaminated soils from different former industrial sites (coking industry, manufactured gas plants).
- An impact diagnosis was performed on sixty offground plots that were left to natural attenuation for more than ten years.

Materials and devices

- 60 PVC lysimeters
- 3 contaminated soils from former industrial sites
- variable initial surface management
- followed by nine to seven years natural attenuation

Sampling & Analysis

- soil and leachate sampling in March 2008
- vegetation determination
- pH, PAH and water analysis
- statistical analysis of data: PCA

Oct 1996 May 1998 April 2000

- bare soil
- **R** rye grass
- A alfalfa
- **RR** rye grass + red clover

Initial time analysis

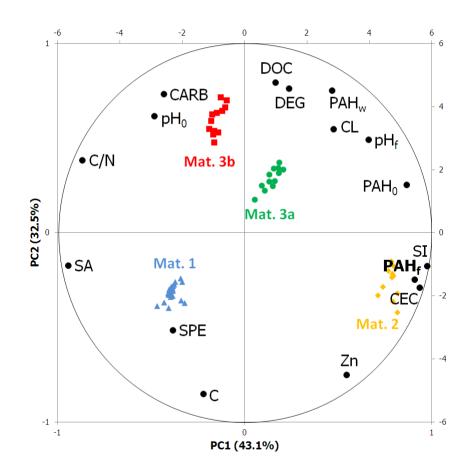

- correlation of initial PAH concentration with silt and CEC
- different materials are evenly distributed in projection plan

Final time analysis

- final PAH concentration well explained and linked to CEC and silt content
- plant diversity (SPE) is not controlled by soil properties or contamination
- degradation rate (DEG) linked to DOC and PAH in leached water
- PAH concentration in leached water were rather low and correlated to DOC

Global treatment performances

- up to 73% dissipation of PAH
- lowest performance obtained for lowest initial PAH concentration
 - possible effect of lower availability due to previous ageing
- tendency to highest vegetation diversity for lowest PAH concentration
 - residual toxic effect or heritage of management practices

Conclusion

- These results clearly promote natural attenuation as a performing technique for contaminated soil remediation and management.
- Best degradation results were obtained for highest initial concentrations and seemed to be improved by liming and low silt and CEC values.
- Fine fractions appeared as central in explaining these soil reactivity and should be looked at more closely.

Conclusion

- Though dense on all materials, vegetation cover diversity still seemed negatively affected by initial PAH concentration.
- Long-term studies such as this one are still necessary to confirm these results and incite stakeholders to consider this technique as a realistic treatment alternative.

Acnowledgements

- The authors acknowledge with gratitude the technical help of the GAIA association (vegetation description) and of B. Genest and C. Barnier (soil sample and analysis).
- They also wish to thank J.-C. Begin, A. Bouchard, B. Colin, P. Henner, S. Colin, A. Rakoto, C. Saison, who set-up and helped maintain the devices, with the financial support of ADEME and EDF-GDF.
