*Abstract*

Between 2001 and 2009, the area of Naples, South Italy, repeatedly hit the headlines of national and international media due to the waste management crisis that on many occasions filled up the streets of the region with huge piles of waste. What soon emerged as the main bone of contention concerned the connections between the population's health and the presence of dumps on the territory. What the risks for health actually were, who was entitled to assess them, and whether pollution from proximity to dumps caused health problems were all topics that came to the fore during a debate that took place within the Italian epidemiological community, alongside the political and governance crisis.

*Keywords:* waste management, epidemiology, Naples (Italy), agnotology

All scientific work is incomplete - whether it be observational or experimental. All scientific work is liable to be upset or modified by advancing knowledge. That does not confer upon us a freedom to ignore the knowledge we already have, or to postpone the action that it appears to demand at a given time.<sup>2</sup>

Austin Bradford Hill

### **Introduction**

Acerra, outskirts of Naples, South Italy, 17 August 2004, about 1 pm. Two men cling to the top of a crane inside a building site, in the suffocating heat of a summer afternoon. At the foot of the crane, a group of people has gathered to support them: these are citizens from Acerra, a town of

55,000, which is slated to host Europe's largest waste-to-energy incinerator. The two men on the crane are the mayor of Acerra, Espedito Marletta, and a Senator of the Italian Republic, Tommaso Sodano, both from the radical left party Rifondazione Comunista (Communist Reestablishment). Below the crane, beside the citizens, stands a group of people in uniforms: these are the deputy police commissioner of Naples, Antonio De Jesu, and his agents. De Jesu orders the two men on the crane to come down, but the two do not comply. Negotiations stall for a while, before De Jesu orders agents to intervene and disperse the protest. Marletta and Sodano are placed under arrest and brought to the police headquarters, where they are charged with invasion of private ground and threats against a public official.

The image of two state officers staging a blatant protest by challenging a body of the very state they represent is among the most emblematic of the waste management crisis that rocked the region of Campania and its capital, Naples, from 1994 to 2009. Especially after this incident in 2004, the crisis filled the pages of newspapers and news broadcasts, bringing to light, both nationally and internationally, an extremely complex network of processes and actors, and causing one of the longest-running media scandals in recent Italian history. Most contemporary Italian media would refer to it as the Campanian “waste emergency,” because indeed a state of emergency had formally been declared in 1994. But apart from the legal phrasing, can a fifteen-year long process be called an emergency at all? And what did it entail for the Campanian society?

In the last decade, a number academic and journalistic publications have sought to respond to this and other unresolved questions related to the crisis. Legal, political, managerial, environmental, and sociological aspects have been scrutinized, as have the involvement of the local mafia—the camorra—and that of local and national administrations.<sup>3</sup> The literature on the crisis brings to the forefront opinions and accounts of technology experts, policymakers, and

---

<sup>3</sup> Though in international literature the word “mafia” tends to be indiscriminately attributed to a variety of criminal organisations, one should keep in mind that significant differences exist between, for example, the Sicilian mafia and the Neapolitan camorra, in terms of structure, organization, involvement in illegal activities, etc. For an initiation to the recent history of camorra, see: Francesco Barbagallo, *Il potere della camorra (1973-1998)* (Torino: Einaudi, 1999). On the mass media and the waste crisis, see: Rossella Savarese, *Galli sulla monnezza. Silenzi, grida e bugie sui rifiuti in Campania* (Roma: Franco Angeli, 2009).

citizens living in the affected areas.<sup>4</sup> Works by journalist Alessandro Iacueli and engineer Paolo Rabitti, for example, have scrupulously reconstructed the chronology, main legislative and political issues of the Campanian case, and detailed the roles and actions of actors involved.<sup>5</sup>

More reflexive works started to emerge towards the formal end of the crisis (December 2009), and aspects of the Campanian crisis have been analyzed by geographers, political scientists, and environmental scientists. Geographers have shown how the camorra progressively took control of the regional waste management sector by replacing the formal regulatory system with an informal one; surprisingly, however, much less academic interest has been shown towards illegal waste disposal activities by Northern and Central Italy's entrepreneurs.<sup>6</sup> Political scientists have argued that delays in the transition to industrial treatment and recycling can be explained by institutional proliferation (i.e., ad hoc creation of a large number of public agencies to which to entrust urban waste management), clientelism, and unstable political executives who favored political expedience over technical expertise.<sup>7</sup> While stressing major discrepancies between the data on produced and disposed waste in official statistics, economists have formulated a new system of environmental accounting to provide a more accurate assessment of the figures of waste generation and disposal in Campania, in contrast to analytical tools employed in official statistics.<sup>8</sup>

Other studies have provided more sociologically and anthropologically oriented

perspectives: the environmental history and sociology.<sup>9</sup> Some scholars have sought to understand the relations between territory, populations, and waste, for example by analyzing the numerous mobilizations against incinerators and landfills in Campania. In particular, environmental historian Marco Armiero has included the Campanian issue within the framework of the environmental justice movement, which merges social and environmental issues:<sup>10</sup> by framing the crisis within Italy's historical post-“unification” context,<sup>11</sup> he has shown the role of racialization in the Campanian issue, the contamination of the region's land being often summarily ascribed to a historical anthropological diversity—read, inferiority—of Southern Italians with respect to peoples of the rest of the peninsula.<sup>12</sup> The racialization framing of the crisis allowed Armiero to liken struggles of Campanian citizens against the opening of landfills and incinerators to those of populations of the global South against industrial mega-projects, or those led by marginalized Afro-American communities in the US.<sup>13</sup>

Still other studies, countering a simplistic narrative ascribing Campanian mobilizations to technophobia or to a NIMBY (Not In My Back Yard) effect, have investigated citizens' protests in terms of a crisis of democracy, showing how resistance was prompted by institutional actors' neglect of any consultation and communication strategy with the affected populations, and their adoption of a technocratic, top-down decision-making agenda, ruled by institutional experts.<sup>14</sup> In

short, these works interpret mobilizations as community struggles or popular resistance movements, capable of going beyond localism and extending their claims to a democratization of sociotechnical decision-making and a more general criticism of the contemporary development model.

Notwithstanding the extensive academic research on the Campanian crisis, very few authors have hinted at the issues of the production of expert knowledge in the process, or recognized the crisis as a paradigmatic example of a sociotechnical controversy, namely one combining a high rate of scientific technicality with social and environmental preoccupations. Those who have taken an interest in the science involved in the waste crisis, have highlighted the difference in attitude of the many stakeholders involved in the Campanian issue vis-à-vis the word of experts, or have focused on the disclosure of epidemiological data, on their appropriation by citizens and on the institutional consequences of such appropriation, or still, have stressed the activists' exploitation of the plurality of voices among experts.<sup>15</sup> Whereas these works focused on conflicts between citizens and institutional experts, a further conflict persisted among those very experts: epidemiologists.

In reconstructing this controversy, my study contributes to an area of research stemming from a plea by sociologists Harry M. Collins and Robert Evans in the early 2000s, on the need for a “wave” of studies on experts and expertise.<sup>16</sup> Collins and Evans's call to arms soon aroused the interest of a number of historians of science, technology, and medicine, as well as of

environmental historians, who have gradually started to reveal in their works the relations between scientific expertise, issues of legitimation and authority, credibility, lobbying activities, legislation, governmental and industrial policies and politics, and especially the production of scientific knowledge and ignorance.<sup>17</sup> Although the area of the regulation of toxic products has been studied in terms of expertise and knowledge (and ignorance) production, this research strand has only marginally addressed the issues raised by waste and waste management.

The production of expertise, knowledge, and ignorance was at the core of the debate that, in the early 2000s, kept many Italian epidemiologists busy assessing whether living close to dumps and incinerators was harmful to human health. Epidemiologists were entrusted with the complex but crucial task of providing the evidence-based arguments that would bolster the edifice of political decision-making. In theory, one would expect that the response to questions such as whether measures on health and safety should be taken to confront the crisis; what kind of provisions these should be; and what form of policies should be implemented to protect citizens' health, would depend to some extent on the epidemiologists' assessment of the links between waste, human health, and the environment. In the Campanian case, however, the translation from theory to practice followed a winding and convoluted path.

Whereas from the epidemiological stance that path would allow the establishment and consolidation of new scientific and medical knowledge, from the political viewpoint the end of the path would end up rather close to its beginning. The uncertainty intrinsically characterizing scientific knowledge was construed by the national government—and in particular by the Ministry of Health—as a pretext for minimizing actions to be taken in devising countermeasures to the crisis. In addition, during the epidemiological controversy, the strategy chosen by institutions to

communicate the developing scientific knowledge to Campanian citizens was highly insufficient, and dictated by a technocratic rationale; and although epidemiologists would recommend that policymakers address the affected communities' legitimate worries, efforts to do so would instead infantilize community members and brand their anxiety as irrational and egoistic. It is to an analysis of the production of epidemiological knowledge and ignorance in the Campanian case that I now turn, after sketching a brief chronology of the crisis.

### **A socio-demographic introduction to Campania and the chronology of the “emergency”**

The southern Italian region of Campania (Fig. 1) is the country's second largest by population, with almost six million people, roughly 10% of the Italian population. The Province of Naples hosts most of the region's citizens, and it is Italy's third-largest province by population, with slightly over three million. Campania is also Italy's most densely populated region (429 people/km<sup>2</sup>), and the Province of Naples is by far the most densely populated province in Italy, with slightly over 2,600 people/km<sup>2</sup> (by comparison, the Province of Milan, the second most densely populated large province, has a density of about 2,000). In spite of this demographic data, however, Campania is third last among the Italian regions in terms of per-capita waste production.<sup>18</sup> It may therefore appear surprising that this region hosted the longest and most bitter waste management crisis in the history of contemporary Italy.

Fig. 1. Provinces of Campania

The picture is clarified by what are the most striking indicators about the region. First, is its per-capita Gross National Income (GNI), which, at €14,422, makes Campania the second-poorest region in Italy (by comparison, Aosta Valley, Italy's richest region, has a per-capita GNI of

---

<sup>18</sup> Data on per capita waste production refer to 2013. ISPRA, Rapporto Rifiuti Urbani, Edizione 2014 – Dati di sintesi, vol. 202/2014, pp. 26-7.

€30,843). Second, the “Density of Waste to be Disposed of” rate—indicating the amount of waste disposed of per day in a given area—in which Naples ranks as the highest Province in Italy.<sup>19</sup> Comparing the latter index with the region’s generalized poverty, it is perhaps easier to understand some of the problems that characterize the region in terms of management of services and infrastructures.

According to the environmentalist association Legambiente, Campania is also the Italian region presenting the highest occurrence of environmental crimes (16% of the national total in 2014),<sup>20</sup> largely a result of the activities of the camorra. Beginning in the 1980s, the camorra turned illegal waste management into a lucrative business, by forming criminal joint ventures with a number of Northern and Central Italian industrialists, so as to bury hazardous waste from that part of the country in southern regions by offering extremely advantageous economic incentives.<sup>21</sup> According to Iacueli, in the late 1980s and early 1990s, a series of ship accidents, and the following judicial investigations, exposed an international traffic of radioactive waste from North Italy to countries like Mozambique, Nigeria, Romania, Somalia, and Venezuela. As a consequence of the first revelations, and of the heightened attention of the Italian judiciary, entrepreneurs involved in the traffic were forced to find new ways to dispose their waste without crossing national borders. This was made possible by the 1989 secret “Villaricca meeting.” On that occasion, some members of the Italian Liberal Party met members of the Freemasonry, a number of chiefs of the Casalesi camorra clan, and a number of figures connected to local waste disposal enterprises, in Villaricca, a town close to the Campanian city of Caserta.<sup>22</sup>

One of the people present at the meeting was the middleman between the Casalesi clan and Licio Gelli, the main leader of the P2 Masonic lodge, who could boast a wide network of contacts

with a number of Northern Italy entrepreneurs, interested in finding new avenues to get rid of their waste at a low cost. The aim of the meeting was to define a grand plan for illegal waste disposal: the final agreement planned that the camorra would offer the disposal services to Northern entrepreneurs at below-market costs through its own transport company. This company was to be authorized by the regional Counselor for Ecology, a member of the Liberal Party, in exchange for a significant percentage of the camorra's revenues.<sup>23</sup> As such the waste crisis represents not so much a criminal aberration, but rather the way in which capitalism was expanding its profits through the socialization of costs. Initially, both urban and toxic waste were transported and abandoned in illegal dumps. As the market grew larger, the system increased its complexity: measures implemented by legal institutions to monitor waste disposal were not able to improve the situation, which reached a point of no return in 1994, when regional public dumps were declared saturated.

Aside from camorra activities (from the mid-1990s, mafia-like organizations involved in environmental crime were usually referred to as *eco-mafias*), the legal waste management cycle in Campania has been characterized by long-term approximation and malpractice, delays in planning and managing adequate dumps, inadequate processing of urban waste in dedicated plants, and by the lack of well-designed schemes for waste recycling. In 2007, to mention one figure, recycling in the Province of Naples added up to as little as 8% (in 2013, however, this percentage had risen to 38.5%).<sup>24</sup> Until the mid-2000s, scarcity of data on the effects of the mismanagement of the waste cycle on populations was also a factor.

The waste "emergency" in Campania is conventionally understood to have started in February 1994, with the entry into force of a decree by Prime Minister, Carlo Azeglio Ciampi (Fig. 2).<sup>25</sup> Through this provision, the Italian government acknowledged the existing environmental emergency in many Campanian dumps, due to the saturation of a number of them. A special commission was constituted to manage the emergency, and an emergency manager (*commissario straordinario*) was appointed and asked to formulate a regional plan for waste disposal. Some

<sup>25</sup> Presidential Decree of 11 February 1994, published on the Official Gazette n. 35, 12 February 1994.

measures were implemented, but they were not sufficient to stop the emergency, so that the Regional Governor was appointed as new emergency manager in 1996. In July 1997, the Governor published a Region Plan for waste disposal, including the construction of two waste-to-energy incinerators and seven fuel-from-waste (FFW) production plants.

Fig. 2. Summary chronology of the Campanian waste crisis (adapted from Armiero, “Is There an Indigenous Knowledge in the Urban North?”)

The Governor then launched a call to find an enterprise to which to entrust the entire waste management cycle and build the dedicated infrastructures by 2000. The project was finally assigned to an Italian-German consortium, FIBE, by privileging criteria of building speed and cost minimization. To speed up the procedure, the Governor used his extraordinary powers, reflecting a state of emergency, which allowed him to ignore the general requirements for environmental impact assessment regulations that would have been otherwise mandatory for building the infrastructures. This decision accelerated the implantation of the facilities and played into the hands of FIBE, to which the tender delegated in addition the unusual right to choose the sites to locate its plants.<sup>26</sup> The public sector washed its hands of the entire problem by entrusting its powers to a corporation, in what turned out to be “a daring experiment in ultra-liberal governmentality.”<sup>27</sup> Eventually, FIBE failed to fulfill its contract: by the end of 2000 there was no sign of incinerators, and the FFW plants built between by 2001 only produced “eco-bales” (namely, packages of compacted waste, [Fig. 3](#)), which were too humid to burn in incinerators. By 2008, these unusable eco-bales, stocked in unsuitable sites and exposed to atmospheric agents, amounted to six million tons.

Mainly because of FIBE’s mismanagement and the slowness in devising waste recycling programs, there was a crisis in waste collection at the beginning of 2001. It was only solved by

<sup>27</sup> Ciro Tarantino, “Strane confessioni. Memoria su alcuni casi di licenziosità nella Napoli del XXI secolo”, in Petrillo (ed.), *Biopolitica di un rifiuto*, 210.

opening old dumps and sending Campanian waste to other Italian regions and to Germany. Although seven FFW plants were opened between 2001 and 2003, the lack of incinerators at which to burn refuse-derived fuel, and of recycling programs meant Campania had to continue using dumps and opening new ones, thus arousing intense citizen mobilizations in the affected areas. These mobilizations often degenerated into violent clashes with the police. The crisis reached its peak in 2007, at which time the government, led by Romano Prodi, selected more sites for dumps and authorized the construction of three new incinerators.

However, the envisaged cure threatened to be worse than the disease, since the choice of building incinerators with a view to solving the crisis was a hotbed of controversy, and not only among the population, but also among the epidemiological community. Uncertainties and strong disagreements simmered over the global consequences of the presence of incinerators on human health; over the kind of emissions generated by plants; and over the technology (older or newer generation) used for the plants.<sup>28</sup> Moreover, the choice of the dump sites, in already socio-economically depressed areas close to Naples, further alienated local populations, with serious repercussions for public order. Indeed, the history of the crisis shows that the government consistently chose the most vulnerable and socio-economically deprived areas for the construction of landfills and incinerators, wrongly assuming—according to Armiero—that people in these areas would be “too poor, too ignorant, or too polluted to react.”<sup>29</sup>

Prev.* (2: 2008): 79-80; Michelangiolo Bolognini et al., “Lettera aperta ai colleghi dell’AIE sul documento ‘Trattamento dei rifiuti e salute’”, *Epidemiol. Prev.* (4-5: 2008): 188.

<sup>29</sup> Marco Armiero, “Seeing Like a Protester”, *Left History* 13 (1: 2008): 65.

In 2008, the new government led by Silvio Berlusconi approved a Legislative Decree that increased to four the number of incinerators to be built and identified ten new dump sites. These were declared areas of national strategic interest and militarized. Any demonstration in proximity to dumps was constituted a felony.<sup>30</sup> Thus, through “exceptional” legislative measures, echoing Giorgio Agamben’s argument that the state of emergency is a typical state of exception—in that ordinary regulations and democratic rights of citizens were suspended, and the border between a democratic and an absolutist state tended to become blurred—protesters were now likened to criminals hindering the operations of the government.<sup>31</sup> Their activities were no longer considered legitimate opposition, but illegal subversion.<sup>32</sup> The new decree, however, by eschewing all existing norms, including communitarian regulations, authorized the disposal of hazardous waste in the new dumps.

In 2009, after the opening of the first and only incinerator at Acerra, the government declared the end of the state of emergency via legislative decree, in spite of the lack of additional planned incinerators, of an adequate waste-recycling program, and of the continued stockpiling of eco-bales in the region. In fact, even the Acerra incinerator was never to work to its full capacity, and was to burn normal waste instead of FFW, thus causing emissions of particulate matter well over the authorized threshold.<sup>33</sup> Witnessing the fact that the issue had only been solved de jure, in 2010 a further waste crisis was recorded, which was only resolved in early 2011.

Throughout the crisis, citizen protests were the most visible component of the issue, and surely its most mediatized element, as emerges from a content analysis in the national edition of one of Italy’s most widely read and influential newspapers, *la Repubblica*.<sup>34</sup> Clashes between protesters and security forces were paralleled by a second, less visible and more technical issue:

that of the assessment of the impact of landfills on human health. The spark that ignited the controversy came not from Italy, but from the UK, more precisely from the pages of the *Lancet Oncology*, the world's leading medical journal, in the summer of 2004.

### **The triangle of death**

In late August 2004, following a period of intense mobilization by the populations residing close to new designated landfills, *The Lancet Oncology* published a report by news writer Kathryn Senior and Alfredo Mazza, a young researcher at the Clinical Physiology Institute of Pisa, which was part of the National Research Council (CNR).<sup>35</sup> According to the report, the occurrence of some types of cancer recorded by one of the Local Health Agencies located in the Naples area was worrying. The concerned district was characterized by one of the worst records of illegal environmental activity in Italy, largely due to camorra-managed activities. Senior and Mazza noted that the data showed that mortality for colorectal and liver cancer, leukemia, and lymphoma, were higher there than in the rest of Campania and Italy. Mazza in particular was convinced of the link between the level of pollution caused by inadequate waste-control methods plus illegal dumping and the high level of cancer mortality in the region.

The report circumscribed the geographical area characterized by the highest environmental risk to the triangle between the Neapolitan towns of Acerra, Nola, and Marigliano (Fig. 4): the zone was nicknamed “the triangle of death” (*il triangolo della morte*) in the article. The catchy title immediately caught the attention of the press. It was true that by the time of the report's publication, the situation of Campanian dumping sites had already caused concern: for example, in July 2004 the European Commission had sent Italy a number of warning letters related to twenty-eight cases of violation of the European Union's (EU) environmental laws. In those letters, most criticism was addressed to the thousands of illegal and uncontrolled dumps present in Italy. In

---

<sup>35</sup> Kathryn Senior and Alfredo Mazza, “Italian ‘Triangle of death’ linked to waste crisis”, *The Lancet Oncology* 5 (September 2004): 525-7.

addition, by that time Italy had already been warned twice for flaunting the regulations of the Hazardous Waste Directive and the Landfill Directive, to the point that the EU referred Italy to the European Court of Justice for further action.<sup>36</sup> Italy was eventually to be condemned in 2010 for failing to adopt sufficient measures to safeguard the safety of the population and the environment.<sup>37</sup> The report nonetheless brought these issues to greater prominence.

The report caused a sensation in a situation that was already critical in terms of public order. It made headlines in all the leading papers in the country. It would soon become the most cited source of evidence throughout the crisis, and it remains so, a decade after its publication. It suddenly awoke the interest of institutions that had remained indifferent theretofore, and raised important questions about the health of Campanian citizens. But the triangle of death report had some serious problems: the methodology it employed appeared controversial.<sup>38</sup> And there was more: it was a journalistic report, not a peer-reviewed article. But it had been published in *The Lancet*, which conferred to it a high degree of authority among non-specialists.

Fig. 4. The triangle of death, as represented in Senior and Mazza's reportage

Indeed, immediately after the article's main thesis was reported by *la Repubblica*,<sup>39</sup> its methodology was contested by a group of epidemiologists from the CNR, led by Fabrizio Bianchi, who in a letter to the *Lancet*, warned about the flaws that compromised Senior and Mazza's study. The main mistake the two authors had made, according to the CNR researchers, consisted in basing their claims on an excessive concentration and an a priori choice of geographical delimitation.<sup>40</sup> Thus Senior and Mazza risked neglecting areas outside the chosen one, which might have shown equally alarming indices, and might be even more affected than the one included in

the triangle. Within the triangle itself, the team contended, the pattern of early mortality and congenital malformations (CM) appeared to be heterogeneous.

A much more serious shortcoming of the report was that the claim of a link between waste disposal sites and human health was rushed, misleading, and disproportionate to the data used in the paper. The reply by Bianchi and colleagues was nothing less than an accusation that Mazza had committed scientific malpractice. The accusation was perceived as all the more serious because Mazza was, like his accusers, a researcher at CNR's Institute of Clinical Physiology. The use of a biased methodology—together with the lack of prior consultation with colleagues—could be seen as a blow to the institute's reputation. It certainly gave the impression of a lack of collaboration among researchers from the same institution. However, the CNR epidemiologists' reply to Senior and Mazza did not receive the same degree of interest by the mainstream media: in fact, it received none, conforming to the journalistic adage that the first news release is what count most.<sup>41</sup>

Why did Mazza limit his study to the area of Acerra-Nola-Marigliano? It appears that already in June 2004, journalist Conchita Sannino, writing for *la Repubblica*, had nicknamed the triangle between Acerra, Nola and Marigliano the “triangle of poisons” (*triangolo dei veleni*).<sup>42</sup> Such characterization may imply that this phrase was already common in the area, and it may have favored a biased geographical delimitation of the area to study. What also irritated the CNR team was that Mazza's report risked fueling controversy and jeopardizing the ongoing epidemiological work. Indeed, although Mazza's data may have been the first to be reported in the media, other researchers had been working for several years on the links between landfills and health in the Provinces of Naples and Caserta.

An exploratory study from 2001 cross-referenced the distribution of childhood mortality in the Province of Caserta with the presence of acknowledged landfills.<sup>43</sup> In that year, the study was

presented at an international conference in the UK, but partial results were only published in 2004 within a publication by the National Institute of Health (ISS) dedicated to the evaluation of environmental and health risk with regard to urban and hazardous waste disposal.<sup>44</sup> But the conclusions of the ISS report were nuanced, and the peculiarities of Campanian landfills (presence of a high number of illegal disposal sites) were drowned within the more reassuring national context. In addition, this publication was in Italian, and was part of a series of reports released by the ISS yearly: grey literature read principally by specialists. The ISS report was no *Lancet*, and its resonance remained limited.

So too was the influence of another study, published in Italian in *Epidemiologia & Prevenzione* (E&P), an organ of the Italian Epidemiology Association (AIE), by researchers from seven national and regional health and environment institutions, and also including some of the authors of the 2001 study.<sup>45</sup> This was a mortality study of three Campanian municipalities characterized by a high concentration of legal and illegal waste disposal sites: it highlighted an excess of risk for a number of cancer pathologies, diabetes, and circulatory diseases, compared to the rest of the region, and suggested that improvements in exposure assessment together with the use of a range of health data would contribute to more thorough studies aimed at inferring causal relationships. Significantly, the paper concluded by inviting institutions to communicate with the population in order to contribute to a climate of mutual trust between technicians and the affected communities, and build informed consensus on decision-making.<sup>46</sup>

Results from these early studies may have been based on limited data, and no one dared to frame the issue in terms of a causal link, but they did recommend that governmental institutions intervene in some way in the problem of the landfills. In this respect, the alarm launched by the Director of E&P, Benedetto Terracini, was unambiguous: “There are no doubts: intervention is necessary,” he wrote in an editorial. Action was urgent, he claimed, given the quantity and quality

of available data.<sup>47</sup> Although further studies were needed, there was no point in indefinitely postponing the reclamation of lands or the implementation of firm measures to favor an adequate waste management cycle. The time necessary to find that causal link could be too long for the recovery of lost health and environment to be still viable. Unfortunately, both the suggestion about devising a communication strategy and the one about intervening with reclamation programs would remain dead letters. But deeper studies *were* carried out.

### **Joining forces for deepening studies**

In the same year the *triangle of death* was published, but before its publication, a multidisciplinary group was entrusted by the National Department of Civil Protection to investigate the health impact of waste in the Provinces of Naples and Caserta (referred to as “the multi-institutional study” henceforth). The group included researchers from the World Health Organization (WHO), the ISS in Rome, the Health and Environment Agencies of the Campania Region, and the CNR. The data the group collected were more thorough than those used in the *Lancet* report. This study included larger areas; it needed the group members’ prior consultation before advancing any result, and it followed the usual path of scientific studies. An early feasibility study by the multi-institutional group analyzed data regarding mortality and the incidence of CM at a municipal level: twenty cancer causes and eleven typologies of CM were considered, for which evidence could be found in the literature of some kind of association with landfills and incinerators. The results of this pilot study were presented in January 2005 in Naples, as well as at a number of international

<sup>47</sup> Benedetto Terracini, “Discariche, triangoli e aree calde”. *Epidemiol. Prev.* 28 (6: 2004): 299-300.

conferences,<sup>48</sup> and they were published on the Civil Protection website,<sup>49</sup> in the ISS Bulletin,<sup>50</sup> and in an international journal.<sup>51</sup>

The study identified an area characterized by particularly high rates of mortality and some types of cancer: significantly, it extended far beyond the boundaries of the *Lancet*'s triangle to include municipalities on the border between the Provinces of Naples and Caserta and some coastal towns in the area of Mount Vesuvius. The data showed an excess of mortality of 19% for men in the Province of Caserta and 43% in the Province of Naples. Data for women were even more alarming (23% for Caserta, 47% for Naples).<sup>52</sup> The pilot study concluded that the areas characterized by the highest mortality and CM rates largely coincided with those where illegal landfills and sites of uncontrolled waste disposal were found. A large part of the identified area was included in what was popularly known as the "land of fires" (*terra dei fuochi*), a region characterized by mafia activities, such as frequent arsons of waste and illegal toxic waste dumps. However, the authors cautioned, it was hard to establish a causal link as the area was also characterized by intensive industrial and agricultural activities and a high population density.

While the epidemiological study was developing, epidemiologists became interested in the popular protest against landfills, and to the arguments formulated by citizens in this respect in particular. The development of this lay expertise was captured in an article by science

communicator Cinzia Colombo, also published in *E&P*.<sup>53</sup> Colombo interviewed a number of the activists who had most strongly engaged in the mobilizations of 2004; for example, citizens of Acerra, who justified their opposition to the incinerator by citing the authorities' lack of consultation with local populations, as well as the priority given by the authorities to incinerators rather than recycling and by the already precarious conditions of the Acerra ecosystem. Citizens opposing the opening of new dumps were generally accused of NIMBYism by national newspapers. To overcome this perception, they grounded their opposition in scientific arguments. They provided data showing that the sites chosen by institutional agencies were almost always disused sites against regulations, inadequate for structural, geographic, and especially for sanitary reasons, and that, in addition, those disused caves had often already been used by the camorra, which had buried there large amounts of highly carcinogenic industrial waste.<sup>54</sup>

Citizens were helped in this activity of knowledge co-production by a number of experts, who sympathized with activists' struggles, and with whom a synergy started to develop. In 2005, activists re-activated a public assembly initiative, which had been dormant since the late 1990s, the *Assise della città di Napoli*, which brought together experts from different fields to discuss aspects of the waste crisis on a weekly basis. Thus, as highlighted by Armiero, citizens were indeed developing their own scientific expertise, their "street science."<sup>55</sup> More generally, in scientific controversies such as those on environmental health science, sustainable agriculture, extractive industry, or biomedical research, interactional expertise can be conceptualized as a form of extended peer-review of policy processes, or informal assessment of technology.<sup>56</sup>

On the official expertise side, some controversial methodological issues gradually started to

emerge. Data originating from cluster analysis concerning CM and exposure to polluted sites was certainly useful to epidemiology, and the fact that some of those analyses reported positive associations may have been indicative; nevertheless, only in a few cases were these studies statistically powerful or mutually consistent enough to support specific hypotheses.<sup>57</sup> In addition, international results on excesses of risk for cancer, mortality, and CM, seemed to be in discord.<sup>58</sup> Such shortcomings prompted some researchers to suggest the use of new and more refined tools of investigation, aimed at assessing individual exposure through biological indicators (biomonitoring) and environmental data, and able to control for confounding variables (such as socio-economic factors). Together with the indications coming from the multi-institutional study, the idea of using biomonitoring and applying it to the Campanian case would materialize in one of Europe's largest epidemiological studies: the Studio Epidemiologico Biomonitoraggio Regione Campania, providentially abbreviated as Sebioec.

### **A hotbed of controversy**

The final version of the multi-institutional study was published in 2007: the analysis of general mortality, tumors, and CM over all of the 196 Campanian municipalities and in the presence of over 300 dumping grounds (89 legal and 138 illegal) confirmed that the highest rates of CMs and mortality were found in areas with high concentrations of illegal dumps. The positive correlation found between health and waste was statistically significant, and the data collected had permitted a categorization of municipalities in groups of increasing intensity of exposure to waste.

<sup>57</sup> Nunzia Linzalone and Fabrizio Bianchi, "Studi sul rischio per la salute umana in prossimità di discariche di rifiuti: aggiornamento e prospettive", *Epidemiol. Prev.* 29 (5: 2005): 51-53.

<sup>58</sup> For a summary of these studies, see: Linzalone and Bianchi, "Studi sul rischio", 52.

While underlining limitations on completeness and accuracy, which, it has to be noted, went in any case in the direction of underestimating the risk, the study's authors went as far as to suggest an "important role" of illegal waste dumps on health effects. When combined with indicators of socio-economic deprivation, the data revealed that the most affected populations were those characterized by a lower socio-economic condition: in particular, the town of Acerra was included in the group with the highest risk.<sup>59</sup>

Some of the results of the study's intermediate stages were reported at a conference organized by the Italian Epidemiological Association in late October 2006 in Sicily.<sup>60</sup> The study's final results were made public in April 2007 in Naples, during a public meeting and the report was made available for consultation through the World Wide Web, that is before it could be peer-reviewed and published (that would only occur two years later, in the journal *Occupational and Environmental Medicine*).<sup>61</sup> The decision to post the report online was controversial and caused a bitter procedural diatribe with an office of the Ministry of Health, as we will see. In the same period, the spotlight of national media moved back to Campania, as the mobilization against the reopening of a number of dumps turned violent as citizens trying to prevent garbage trucks from entering the new sites clashed with police.<sup>62</sup>

The alarming results of the multi-institutional study prompted the Commissioner and Director of Civil Protection to ask the region to commission a larger epidemiological investigation,

the Sebiosec Study, aimed at measuring the absorption of pollutants (such as dioxins—a category of endocrine disruptors—and heavy metals) in the blood and maternal milk of a sample of the population residing in sixteen Campanian municipalities. The study, including over 850 participants, was one the largest of its kind in Europe. It also included a questionnaire on individuals' lifestyles, environments, medical histories, dietary habits, and working and reproductive histories. So, together with clinical data, also socio-anthropologic data could be collected.<sup>63</sup> In addition biomonitoring, unlike simple data on cancer occurrence or environmental pollutants, made it possible to describe the detailed circumstances of toxic exposure in the territory. The results of Sebiosec were planned to be ready by 2009, but difficulties in collecting procedures postponed the end of the study until December 2010.<sup>64</sup>

Aside from the launch of Sebiosec, certainly a laudable initiative but only in the medium term, little was made of the study's results in the shorter term with respect to land reclamation—let alone with respect to science communication. Following the 2007 report's release, the Ministry of Health raised some criticism on the study's methodology and the inadequacy of the communication process, but the question did not cause much clamor.<sup>65</sup> While epidemiologists were busy starting up the Sebiosec machine, Naples was going through one of the peaks of the waste crisis: it was again the piles of rubbish bags that were monopolizing media attention. But the quiet did not last: in July 2008, a few months after the fall of the center-left government led by Romano Prodi and the assignment of a new, center-right one, led by Silvio Berlusconi, the multi-institutional report was vehemently attacked by the Director of the Chronic Diseases Prevention Office at the Ministry of Health, Paolo D'Argenio.

According to D'Argenio, the study was misconceived, methodologically wrong, based on

false assumptions, and had therefore obtained unsubstantiated results. In short, it had been absolutely useless, and the contributors' money would have better been used for some less partisan activity. However, he wrote, it had been "sanctified by groups and associations of citizens, and had entered the public debate as an incontrovertible proof of the existence of a link between exposure and damage."<sup>66</sup> We do not know why it took so long for D'Argenio to express his criticism of the study: what we do know is that, starting from 1 August 2008, he left his post at the Ministry of Health and became a director of the Regional Health Agency of Campania.<sup>67</sup> D'Argenio's criticism of the 2007 study centered on three aspects. First of all, he contested the study's methodology: the data used for assessing CM were incomplete, he argued, since for a long time many Campanian hospitals had not collaborated with the regional CM Record Office; as a consequence, areas where hospitals had indeed collaborated had been given a much higher weight than those where they had not. In sum, the analysis may have been "distorted by a gigantic selection bias that destroyed the credibility of the results."<sup>68</sup>

Second, as for mortality clusters, according to D'Argenio, the coincidence of the waste-exposed area and the highest mortality area "did not explain anything," as confounding factors had not been adequately considered. Instead, he argued, it had been known ever since the 1990s, when the ISS had published an "important report" (which, however, D'Argenio did not cite), that mortality in Campania showed excesses in the Provinces of Naples and Caserta: an excess that was linked, amongst other diseases, to lung cancer. Where were the main causes of lung cancer to be found then? Not in illegal waste, but in tobacco smoke and traffic pollution. The index of municipal socio-economically deprivation, D'Argenio maintained, was not sufficient to account for high death rates: these could be explained away by the fact that in those areas there were more smokers, people smoked in public places where it was forbidden, more motorcyclists rode without their helmets, and traffic was out of control.<sup>69</sup>

<sup>68</sup> D'Argenio, "Critiche allo studio", 190.

<sup>69</sup> *Ibid.*, 191.

Finally, in the opinion of the officer of the Ministry of Health, the communication strategy had been wrong. The report's misuse of the study by science popularizers, environmentalist associations, and the media, which, he maintained, had contributed to a wall between the public opinion and civic institutions and mistrust in the population, exactly at the time when the situation of public order was worsening. According to D'Argenio, the publication of the results on the Web in 2007 had been a blunder: the commentary posted alongside it had confused relative and absolute risk. In addition, science writers flirting with radical left-wing associations, led by demagogical figures claiming to protect people from invisible threats, had misinterpreted the data, thus generating the mentioned "widespread conviction" in the population, and ultimately a NIMBY effect.<sup>70</sup>

The authors of the report responded to all of D'Argenio's criticisms with a flat rejection: some of his arguments may in principle be correct, they acknowledged, but had been already covered in the authors' previous publications, or had been long discussed by them; others, like the one on the role of smoke, needed not just to be advanced, but proved through evidence, and studies, and D'Argenio had not done that. Other arguments still, such as the one on communication, sounded specious: the authors retorted that the communicators' task was to be faithful to scientific reality, and also to highlight science's uncertainties. They were implicitly stating that patronizing populations through false reassurances would be dishonest.<sup>71</sup>

D'Argenio's position exemplified the institutional view of the role of citizens in the issue. The rationality of the experts was contrasted to the populace's emotional distortion of facts, and the media were accused of communicating poorly in a setting where the Ministry of Health had not bothered to disseminate any information to the public. Ultimately, D'Argenio conveyed the message that, because of these biases, the report had not proven any link between waste and health: as a consequence, any claim of the existence of such a link was preposterous, and governmental officers like him may as well not take the study's results into account.<sup>72</sup> Such a

<sup>72</sup> D'Argenio, "Critiche allo studio", 191.

recommendation was, in fact, superfluous, since a similar position had already been expressed by Donato Greco, Director of the Prevention Department at the Ministry of Health. In the winter of 2008, Greco had become “the public face of denial,” when declaring to newspapers that the population should not be worried, given the absence of any causal link between dumps and health. And in the spring, in an article where CNR’s Fabrizio Bianchi strongly recommended the launch of a program of land reclamation even in a situation of epidemiological uncertainty, Greco scoffed at that suggestion, ascribing any talk of a link to “the ignorance of innocent populations, the incompetence of some among [his] colleagues, and the illegality of those who [made] a profit from the waste business.”<sup>73</sup>

Whereas Bianchi maintained a more scientifically correct position, by stressing the uncertainties intrinsic to science, Greco’s patronizing attitude was epistemologically weak, but as a main representative of a governmental institution he could enjoy a much larger media attention than Bianchi. In addition, it was repeatedly reported by the media, which did not bother to clarify that whereas Greco and D’Argenio were dissenters who had not carried out any epidemiological work on the Campanian territory, the authors of the multi-disciplinary study came from high-reputed institutions and *had* carried out research on the Campanian situation. Greco claimed the results were uncertain; that no reliable link had been found between landfills and health. Essentially, officers at the Ministry of Health were “us[ing] normal scientific uncertainty to undermine the status of actual scientific knowledge.”<sup>74</sup> They were producing scientific ignorance.<sup>75</sup> But the authors of the 2007 report *had* found a link, and the data were growing increasingly accurate, in the direction of establishing a causal relationship.

D’Argenio returned to the fray in early 2009, when he launched a new attack on the 2007 study, no longer focusing on the communication strategy, but on a procedural aspect<sup>76</sup>: the report’s results had been disclosed not through a peer-reviewed journal, but directly to the public, in a

“Pasteurian” style.<sup>77</sup> That was a reasonable point to raise, but the authors had an equally reasonable response, and it touched upon the ethos of epidemiology: although the need to publish in a peer-reviewed journal was acknowledged (and, in fact, the peer-reviewing process was ongoing for the results of the report), ISS’s Pietro Comba affirmed that “researchers should not, while waiting for incontrovertible evidence, postpone decisions or, worse, interpret the absence of evidence as the proof of absence of risks”.<sup>78</sup> That was exactly what the governmental experts were doing.

Eventually, however, the attempt to infantilize the affected communities by propagating a narrative of absence of risks backfired. In such an acute political and governance crisis, and in the presence of publicly known data on waste and health, the more passionately governmental experts denied any risk, the less the population trusted them.

On 31 December 2009, the state of emergency related to Campanian waste management was declared over (see above). Was the epidemiological controversy closed by then? In a way, it was. But not in the way one would have expected. By the very time epidemiology had proven the link between waste and health, the government had decided to behave as though there was no such link. It just silenced the question, aided by the militarization of the landfill areas, which, at the expense of citizens’ democratic rights, made it easier for the government to remove garbage from towns and dispose it indiscriminately in new landfills.

The government, not the epidemiological community, was in charge of devising a solution to the crisis, and the chosen solution was to pretend that, with less rubbish in the streets, health problems would no longer be a focal point. By removing 170,000 tons of garbage from the streets of Naples and its province, the government claimed the case to be closed. For the government, the militarization of the landfill territories and the cleanup of streets was meant to signify the depoliticization of the whole waste issue, its transformation into a non-issue, its “falling back to sleep,” to use Bruno Latour’s words.<sup>79</sup>

<sup>78</sup> Pietro Comba, “La risposta degli autori”, *Epidemiol. Prev.* 33 (1-2: 2009): 3-4. The quote is from p. 4.

<sup>79</sup> Bruno Latour, “Turning Around Politics - A Note on Gerard de Vries’ Paper”. *Social Studies of Science* 37 (5: 2007): 818. See also, for a Latourian perspective over waste management: Myra J Hird et al., “Making waste management public (or falling back to sleep)”, *Soc. Stud. Sci.* 44 (3: 2014): 441-65.

However, D'Alisa and Armiero argue, “the government’s obsession with urban waste and cleanup operation have been instrumental in concealing the actual contamination caused by toxic waste”; in addition, the quantitative analysis they make of the flows of produced waste and regional landfills’ capacities reveals that two million tons of garbage went missing, and this is highly worrying in a territory characterized by heavy *eco-mafias*’ activities and illegal disposals.<sup>80</sup>

A final point should be raised with respect to the results of the Sebiorec study, which were released in late 2010. The study eventually proved that, while the rate of pollutants contained in blood and milk was not significantly higher than the levels measured in other non-industrial environments, a number of harmful substances (arsenic, lead, mercury) were indeed detected. Living close to illegal dumps for dangerous waste was found to indicate higher exposure to organic substances such as dioxins, furans, and polychlorinated biphenyls, due to the practice of arson. As noted by CNR communicator, Liliana Cori, who took part in the sociological component of Sebiorec, the most important result for a study aimed at understanding the distribution of the levels of exposure to pollutants was the great variability of values among different areas observed for the analyzed substances, which could help designing targeted disposal strategies and prevention schemes.<sup>81</sup>

## Conclusions

The analysis of the Campanian epidemiological debate allows us to pinpoint two distinct moments, characterized by similar dynamics and different outcomes, both of which fit within the framework of studies on the production of knowledge and ignorance. The first concerns the publication of the “triangle of death” article in the summer of 2004. The article was highly mediatized, but its

---

methodology and form of publication (a non peer-reviewed report) were stigmatized by the Italian epidemiological community. Although the authors of the report may have erred in their methodology and communication strategy, they were not aiming to produce deliberately inaccurate results. Be that as it may, the inaccuracies contained in the report shaped a biased public perception of the geographical borders of the most “toxified” area. The image of the *triangle of death* is still central to contemporary narratives about the Campanian waste crisis, and further studies—whether simultaneous to, preceding, or following the *Lancet*’s—did not have an equivalent impact on public perception. On a positive side, however, the loud alarm bell rung by the report raised public awareness of toxic waste in Campanian lands, and its possible links to human health.

The second moment of the debate, starting with the publication of the multi-institutional study in 2007, generated an altercation between the two camps, “deniers” and “precautionists”: the former absolutely denying any sort of link between health and waste dumps, the latter affirming the existence of some link, while stressing the uncertainties of the science involved. The two camps were clearly divided into governmental (denier) and non-governmental (precautionist) experts. The first camp included agents from the Ministry of Health; the second, a much larger spectrum including experts from CNR, ISS, and WHO. Despite their numerical inferiority, and thanks to the power conferred to them by being governmental representatives, deniers managed to fabricate doubt about the health-waste association.

The debate centered on two elements in particular: a methodological one and a procedural one. The methodological element regarded the definition of the area in which to lead a study and the choice of units for clusters analysis. The procedural element regarded the dissemination of scientific results before peer review. The dispute had practical consequences, in that, sticking to a paradigm that held the absence of unambiguous evidence of risks to be evidence of absence of such risks, government experts tried to reassure the population. Can these experts be said to have been producing ignorance? In its weaker meaning of deliberately denying reliably increasing

evidence that was accumulating around the health-to-waste relation, they can. In a stronger and more literal version of “ignorance production,” the claim would only be partially accurate, in that these experts were in fact not producing their own scientific evidence to disprove others’ claims. In the presence of a scientific controversy, ultimately, such attempts at reassurance beyond reasonable doubt proved counterproductive, as citizens perceived they were being deliberately denied the truth by the institutional representatives.

Whereas the citizens’ mobilization against landfills and incinerators developed throughout the epidemiological debate, its intensity only decreased following the government’s decision to militarize sensitive areas and declare demonstrations there illegal. Such militarization, joined to the esthetic and much mediatized operation of the cleanup of the Campanian capital city, represented the ultimate sign that the controversy—or rather, its public face—had fallen back to sleep.
