HAL is a multi-disciplinary open access archive for the deposit and dissemination of scientific research documents, whether they are published or not. The documents may come from teaching and research institutions in France or abroad, or from public or private research centers.

L’archive ouverte pluridisciplinaire HAL, est destinée au dépôt et à la diffusion de documents scientifiques de niveau recherche, publiés ou non, émanant des établissements d’enseignement et de recherche français ou étrangers, des laboratoires publics ou privés.
CONVERGENT SEMIDEFINITE PROGRAMMING RELAXATIONS FOR GLOBAL BILEVEL POLYNOMIAL OPTIMIZATION PROBLEMS∗

V. JEYAKUMAR†, J. B. LASSERRE‡, G. LI†, AND T. S. PHẠM§

Abstract. In this paper, we consider a bilevel polynomial optimization problem where the objective and the constraint functions of both the upper-and the lower-level problems are polynomials. We present methods for finding its global minimizers and global minimum using a sequence of semidefinite programming (SDP) relaxations and provide convergence results for the methods. Our scheme for problems with a convex lower-level problem involves solving a transformed equivalent single-level problem by a sequence of SDP relaxations, whereas our approach for general problems involving a nonconvex polynomial lower-level problem solves a sequence of approximation problems via another sequence of SDP relaxations.

Key words. bilevel programming, global optimization, polynomial optimization, semidefinite programming hierarchies

1. Introduction. Consider the bilevel polynomial optimization problem

\[
(P) \min_{x \in \mathbb{R}^n, y \in \mathbb{R}^m} f(x, y)
\]

subject to \( g_i(x, y) \leq 0, \ i = 1, \ldots, s, \ y \in Y(x) := \arg\min_{w \in \mathbb{R}^m} \{ G(x, w) : h_j(w) \leq 0, j = 1, \ldots, r \}, \)

where \( f : \mathbb{R}^n \times \mathbb{R}^m \to \mathbb{R}, \) \( g_i : \mathbb{R}^n \times \mathbb{R}^m \to \mathbb{R}, \) \( G : \mathbb{R}^n \times \mathbb{R}^m \to \mathbb{R}, \) and \( h_j : \mathbb{R}^m \to \mathbb{R} \)

are all polynomials with real coefficients, and we make the blanket assumption that the feasible set of \( (P) \) is nonempty, that is, \( \{(x, y) \in \mathbb{R}^n \times \mathbb{R}^m : g_i(x, y) \leq 0, i = 1, \ldots, s, y \in Y(x)\} \neq \emptyset. \)

Bilevel optimization provides mathematical models for hierarchical decision making processes where the follower’s decision depends on the leader’s decision. More precisely, if \( x \) and \( y \) are the decision variables of the leader and the follower, respectively, then the problem \((P)\) represents the so-called optimistic approach to the leader

753
and follower’s game in which the follower is assumed to be cooperative, and so the leader can choose the solution with the lowest cost. We note that there is another approach, called the pessimistic approach, which assumes that the follower may not be cooperative and hence the leader will need to prepare for the worst cost (see, for example, [11, 44]).

The bilevel optimization problem \((P)\) also requires that the constraints of the lower-level problem are independent of the upper-level decision variable \(x\) (i.e., the functions \(h_j\) do not depend on \(x\)). This independence assumption guarantees that the optimal value function of the lower-level problem is automatically continuous and so plays an important role later in establishing convergence of our proposed approximation schemes for finding global optimal solutions of \((P)\). A discussion on this assumption and its possible relaxation is given in Remark 4.9 of the paper.

As noted in [31], the models of the form \((P)\) cover the situations in which the leader can only observe the outcome of the follower’s action but not the action itself, which, has important applications in economics such as the so-called moral hazard model of the principal-agent problem. In particular, in the special case where \(g_i\) depends only on \(x\), the sets \(\{x \in \mathbb{R}^n : g_i(x) \leq 0\}\) and \(\{w \in \mathbb{R}^m : h_j(w) \leq 0\}\) are both convex sets, problem \((P)\) has been studied in [31], and a smoothing projected gradient algorithm has been proposed to find a stationary point of problem \((P)\). On the other hand, the functions \(f, g_i, G, h_j\) of \((P)\) in [31] are allowed to be continuously differentiable functions which may not be polynomials in general. For applications and recent developments of solving more general bilevel optimization problems, see [3, 9, 10, 11, 43].

In this paper, in the interest of simplicity, we focus on the optimistic approach to the hierarchical decision making process and develop methods for finding a global minimizer and global minimum of \((P)\). We make the following key contributions to bilevel optimization:

- **A novel semidefinite (SDP) hierarchy for bilevel polynomial problems.** We propose general purpose schemes for finding global solutions of the bilevel polynomial optimization problem \((P)\) by solving hierarchies of semidefinite programs and establish convergence of the schemes. Our approach makes use of the known techniques of bilevel optimization and the recent developments of (single-level) polynomial optimization, such as the sums-of-squares decomposition and SDP hierarchy, and does not use any discretization or branch-and-bound techniques as in [17, 37, 44].

- **Convex lower-level problems: Convergence to global solutions.** We first transform the bilevel polynomial optimization problem \((P)\) with a convex lower-level problem into an equivalent single-level nonconvex polynomial optimization problem. We show that the values of the standard SDP relaxations of the transformed single-level problem converge to the global optimal value of the bilevel problem \((P)\) under a technical assumption that is commonly used in polynomial optimization (see [26] and references therein).

- **Nonconvex lower-level problems: A new convergent approximation scheme.** By examining a sequence of \(\epsilon\)-approximation (single-level) problems of the bilevel problem \((P)\) with a not necessarily convex lower-level problem, we present another convergent sequence of SDP relaxations of \((P)\) under suitable conditions. Our approach extends the sequential SDP relaxations, introduced in [27] for parameterized single-level polynomial problems, to bilevel polynomial optimization problems.
GLOBAL BILEVEL POLYNOMIAL OPTIMIZATION 755

It is important to note that local bilevel optimization techniques, studied extensively in the literature [3, 10], apply to broad classes of nonlinear bilevel optimization problems. In the present work, we employ some basic tools and techniques of semialgebraic geometry to achieve convergence of our SDP hierarchies of global nonlinear bilevel optimization problems, and so our approaches are limited to studying the class of polynomial bilevel optimization problems.

Moreover, due to the limitation of the SDP solvers, our proposed scheme can be used to solve problems of small or moderate size and it may not be able to compete with the ad hoc (but computationally tractable) techniques, such as branch-and-bound and discretization schemes. For instance, underestimation and branch-and-bound techniques were used in [1, 17, 37] and a generalized semi-infinite programming reformulation together with a discretization technique was employed in [44]. See http://bilevel.org/ for other references of computational methods of bilevel optimization.

However, it has recently been shown that by exploiting sparsity and symmetry, large-size problems can be solved efficiently, and various numerical packages have been built to solve real-life problems such as the sensor network localization problem [24]. We leave the study of solving large-size bilevel problems for future research as it is beyond the scope of this paper.

The outline of the paper is as follows. Section 2 gives preliminary results on polynomials and continuity properties of the solution map of the lower-level problem of (P). Section 3 presents convergence of our sequential SDP relaxation scheme for solving the problem (P) with a convex lower-level problem. Section 4 describes another sequential SDP relaxation scheme and its convergence for solving the general problem (P) with a not necessarily convex lower-level problem. Section 5 reports results of numerical implementations of the proposed methods for solving some bilevel optimization test problems. The appendix provides details of various technical results of semialgebraic geometry used in the paper and also proofs of certain technical results.

2. Preliminaries. We begin by fixing notation, definitions, and preliminaries. Throughout this paper $\mathbb{R}^n$ denotes the Euclidean space with dimension $n$. The inner product in $\mathbb{R}^n$ is defined by $\langle x, y \rangle := x^T y$ for all $x, y \in \mathbb{R}^n$. The open (resp., closed) ball in $\mathbb{R}^n$ centered at $x$ with radius $\rho$ is denoted by $B(x, \rho)$ (resp., $\overline{B}(x, \rho)$). The nonnegative orthant of $\mathbb{R}^n$ is denoted by $\mathbb{R}^n_+$ and is defined by $\mathbb{R}^n_+ := \{(x_1, \ldots, x_n) \in \mathbb{R}^n \mid x_i \geq 0\}$. Denote by $\mathbb{R}[x]$ the ring of polynomials in $x := (x_1, x_2, \ldots, x_n)$ with real coefficients. For a polynomial $f$ with real coefficients, we use $\deg f$ to denote the degree of $f$. For a differentiable function $f$ on $\mathbb{R}^n$, $\nabla f$ denotes its derivative. For a differentiable function $g : \mathbb{R}^n \times \mathbb{R}^m \to \mathbb{R}$, we use $\nabla_x g$ (resp., $\nabla_y g$) to denote the derivative of $g$ with respect to the first variable (resp., second variable). We also use $\mathbb{N}$ (resp., $\mathbb{N}_{\geq 0}$) to denote all the nonnegative (resp., positive) integers. Moreover, for any integer $t$, let $\mathbb{N}_t := \{\alpha \in \mathbb{N}^n : \sum_{i=1}^n \alpha_i \leq t\}$. For a set $A$ in $\mathbb{R}^n$, we use $\text{cl}(A)$ and $\text{int}(A)$ to denote the closure and interior of $A$. For a given point $x$, the distance from the point $x$ to a set $A$ is denoted by $d(x, A)$ and is defined by $d(x, A) = \inf\{\|x - a\| : a \in A\}$.

We say that a real polynomial $f \in \mathbb{R}[x]$ is sum-of-squares if there exist real polynomials $f_j, j = 1, \ldots, r$, such that $f = \sum_{j=1}^r f_j^2$. The set of all sum-of-squares real polynomials in $x$ is denoted by $\Sigma^2[x]$. Moreover, the set of all sum-of-squares real polynomials in $x$ with degree at most $d$ is denoted by $\Sigma^2_d[x]$. We also recall some notions and results of semialgebraic functions/sets, which can be found in [6, 15].

**Definition 2.1 (semialgebraic sets and functions).** A subset of $\mathbb{R}^n$ is called semialgebraic if it is a finite union of sets of the form $\{x \in \mathbb{R}^n : f_i(x) = 0, i = 0, \ldots, k\}$, where $f_i$ are real polynomials.
1, \ldots, k; f_i(x) > 0, i = k + 1, \ldots, p\}$, where all $f_i$ are real polynomials. If $A \subset \mathbb{R}^n$ and $B \subset \mathbb{R}^p$ are semialgebraic sets, then the map $f: A \rightarrow B$ is said to be semialgebraic if its graph $\{(x, y) \in A \times B : y = f(x)\}$ is a semialgebraic subset in $\mathbb{R}^n \times \mathbb{R}^p$.

Semialgebraic sets and functions are important classes of sets and functions and they have important applications in nonsmooth optimization (for a recent development, see [7]). In particular, they enjoy a number of remarkable properties. Some of these properties, which are used later in the paper, have been summarized in Appendix A for the convenience of the reader.

We now present a preliminary result on Hölder continuity of the solution mapping of the lower-level problem. As a consequence, we provide an existence result of the solution set of general parametric optimization problems (see, for example, [19, 41]). This property plays an important role in establishing the existence of solutions for bilevel programming problems and equilibrium problems (see, for example, [33] and Corollary 2.5). Next, we show that the solution map of a lower-level problem is not Hölder continuous at 0 for any $\tau > 0$, and $\tau$ in general is not continuous for any exponent $\tau \in (0, 1]$ if there exist $\delta, \epsilon, c > 0$ such that

$$d(y, F(\bar{x})) \leq c \|x - \bar{x}\|^\tau$$

for all $y \in F(x) \cap B_n(\bar{y}, \epsilon)$ and $x \in B_n(\bar{x}, \delta)$.

In the case when $\tau = 1$, this property is often referred to as calmness and has been well-studied in nonsmooth analysis (see, for example, [8]). We first see that even in the case, where $G$ is a continuously differentiable function and the set $\{y \in \mathbb{R}^m : h_j(y) \leq 0\}$ is compact, the solution map $Y: \mathbb{R}^n \Rightarrow \mathbb{R}^m$ of the lower-level problem $Y(x) := \text{argmin}_{y \in \mathbb{R}^m} \{G(x, y) : h_j(y) \leq 0, j = 1, \ldots, r\}$ is not necessarily Hölder continuous for any exponent $\tau > 0$.

**Example 2.2** (failure of Hölder continuity for the solution map of the lower-level problem: nonpolynomial case). Let $f: \mathbb{R} \rightarrow \mathbb{R}$ be defined by

$$f(y) = \begin{cases} \frac{1}{e^y} & \text{if } y \neq 0, \\ 0 & \text{if } y = 0. \end{cases}$$

Consider the solution mapping $Y(x) = \text{argmin}_{y \in \mathbb{R}} \{G(x, y) : y^2 \leq 1\}$ for all $x \in [-1, 1]$, where $G(x, y) = (x - f(y))^2$. Then, it can be verified that $G$ is a continuously differentiable function (indeed it is a $C^\infty$ function) and

$$Y(x) = \begin{cases} \{\pm \sqrt{\frac{1}{\ln 2}}\} & \text{if } x \in (0, 1], \\ \{0\} & \text{if } x \in [-1, 0]. \end{cases}$$

We now see that the solution mapping $Y$ is not Hölder continuous at 0 with exponent $\tau$ for any $\tau \in (0, 1]$. To see this, let $x_k = e^{-k} \rightarrow 0$ and $y_k = \sqrt{k} \in Y(x_k)$. Then, for any $\tau \in (0, 1]$,

$$\frac{|x_k|^\tau}{d(y_k, Y(0))} = \frac{e^{-\tau k}}{\sqrt{k}} = \frac{\sqrt{\epsilon}}{e^{\tau k}} \rightarrow 0.$$

So, the solution mapping is not Hölder continuous at 0 for any $\tau \in (0, 1]$.

The Hölder continuity of the solution set of general parametric optimization problems has been established under suitable regularity conditions; for example, see [19, 41]. This property plays an important role in establishing the existence of solutions for bilevel programming problems and equilibrium problems (see, for example, [33] and Corollary 2.5). Next, we show that the solution map of a lower-level problem
of a bilevel polynomial optimization problem is always Hölder continuous with an explicit exponent which depends only on the degree of the polynomial involved and the dimension of the underlying space. This result is based on our recent established Łojasiewicz inequality for nonconvex polynomial systems in [30].

For $m, d \in \mathbb{N}$, denote
\begin{equation}
R(m, d) := \begin{cases} 
1 & \text{if } d = 1, \\
\frac{1}{d(3d - 3)^{m-1}} & \text{if } d \geq 2.
\end{cases}
\end{equation}

**Theorem 2.3** (Hölder continuity of solution maps in the lower-level problem: polynomial case). Let $h_j, j = 1, \ldots, r$, and $G$ be polynomials with real coefficients. Denote $d := \max\{\deg h_j, \deg G(x, \cdot)\}$. Suppose that $F := \{y \in \mathbb{R}^m : h_j(y) \leq 0\}$ is compact. Then, the solution map $Y : \mathbb{R}^n \rightharpoonup \mathbb{R}^m$ in the lower-level problem $Y(x) := \text{argmin}_{y \in \mathbb{R}^m} \{G(x, y) : h_j(y) \leq 0, j = 1, \ldots, r\}$ satisfies the following Hölder continuity property at each point $\bar{x} \in \mathbb{R}^n$: for any $\delta > 0$, there is a constant $c \in (0, 1) \cup \{0\}$ such that
\begin{equation}
Y(x) \subset Y(\bar{x}) + c \|x - \bar{x}\|^\tau \mathcal{B}_{\mathbb{R}^m}(0, 1) \text{ whenever } \|x - \bar{x}\| \leq \delta
\end{equation}
for some $\tau \in [\tau_0, 1]$ with $\tau_0 = \max\{\frac{1}{R(m+r+1,d+1)}, \frac{2}{R(m+r,2d)}\}$. In particular, $Y$ is Hölder continuous at $\bar{x}$ with exponent $\tau_0$ for any $\bar{x} \in \mathbb{R}^n$.

**Proof.** For any fixed $x \in \mathbb{R}^n$, define $\Phi(x) = \min_{y \in \mathbb{R}^m} \{G(x, y) : h_j(y) \leq 0, j = 1, \ldots, r\}$ and let
\[
\Phi_x(y) := \sum_{i=1}^r [h_j(y)]_+ + |\Phi(x) - G(x, y)|.
\]

Then, for all fixed $x$,
\[
\{y \in \mathbb{R}^n : \Phi_x(y) = 0\} = Y(x) = \{y \in \mathbb{R}^m : h_j(y) \leq 0 \text{ as } j = 1, \ldots, s, \text{ and } \Phi(x) - G(x, y) = 0\}.
\]

Note that $F$ is compact. Now, the Łojasiewicz inequality for nonconvex polynomial systems [30, Corollary 3.8] gives that there is a constant $c_0 > 0$ such that
\begin{equation}
d(y, Y(\bar{x})) \leq c_0 \Phi_{\bar{x}}(y)^\tau \text{ for all } y \in F
\end{equation}
for some $\tau \in [\tau_0, 1]$ with $\tau_0 = \max\{\frac{1}{R(m+r+1,d+1)}, \frac{2}{R(m+r,2d)}\}$. Further, there is a constant $L > 0$ such that
\begin{equation}
|G(x, y) - G(\bar{x}, y)| \leq L\|x - \bar{x}\|
\end{equation}
for all $y \in F$ and all $x$ with $\|x - \bar{x}\| \leq \delta$. Denote $c := (2\beta^{-1}L)^\tau$ with $\beta := c_0^{-\frac{1}{\tau}} > 0$. For any $y \in Y(x)$ we select now $\bar{y} \in Y(\bar{x})$ satisfying $\|y - \bar{y}\| = d(y, Y(\bar{x}))$. To finish the proof, it suffices to show that
\begin{equation}
\|y - \bar{y}\| \leq c \|x - \bar{x}\|^\tau.
\end{equation}

To see this, note that $|\Phi(\bar{x}) - G(\bar{x}, y)| = \Phi_x(y) \geq \beta d(y, Y(\bar{x}))^\frac{1}{\tau} = \beta \|y - \bar{y}\|^\frac{1}{\tau}$. Since $\bar{y} \in Y(\bar{x})$, it follows that $G(\bar{x}, \bar{y}) = \Phi(\bar{x}) \leq G(\bar{x}, y)$, and hence
\begin{equation}
\|y - \bar{y}\|^\frac{1}{\tau} \leq \beta^{-1} |\Phi(\bar{x}) - G(\bar{x}, y)| = \beta^{-1} (G(\bar{x}, y) - G(\bar{x}, \bar{y})).
\end{equation}
Furthermore, as \( y \in Y(x) \), \( G(x, y) \leq G(x, \bar{y}) \), and therefore (2.4) gives us that
\[
G(\bar{x}, y) - G(\bar{x}, \bar{y}) = (G(\bar{x}, y) - G(x, y)) + (G(x, y) - G(x, \bar{y})) + (G(x, \bar{y}) - G(\bar{x}, \bar{y})) \\
\leq (G(\bar{x}, y) - G(x, y)) + (G(x, \bar{y}) - G(\bar{x}, \bar{y})) \\
\leq 2L\|x - \bar{x}\| \quad \text{as} \quad y, \bar{y} \in F.
\]
This together with (2.6) yields
\[
\|y - \bar{y}\| \leq \beta^{-1}(G(\bar{x}, y) - G(\bar{x}, \bar{y})) \leq 2\beta^{-1}L\|x - \bar{x}\|.
\]
Thus
\[
d(y, Y(\bar{x})) = \|y - \bar{y}\| \leq c\|x - \bar{x}\|^\tau,
\]
which verifies (2.5) and completes the proof of the theorem.

In general, our lower estimate of the exponent \( \tau \) will not be tight. We present a simple example to illustrate this.

Example 2.4. Consider the solution mapping \( Y(x) = \text{argmin}_{y \in \mathbb{R}} \{(x - y^2)^2 : y^2 \leq 1\} \) for all \( x \in [-1, 1] \). Clearly,
\[
Y(x) = \begin{cases} 
\{\pm \sqrt{x}\} & \text{if} \quad x \in [0, 1], \\
\{0\} & \text{if} \quad x \in [-1, 0].
\end{cases}
\]
So, the solution mapping is Hölder continuous at 0 with exponent 1/2. On the other hand, our lower estimate gives \( \tau_0 = 1/84 \). So, the lower estimate is not tight.

**Corollary 2.5 (existence of global minimizer).** For the bilevel polynomial optimization problem \( (P) \), let \( K = \{(x, y) \in \mathbb{R}^n \times \mathbb{R}^m : g_i(x, y) \leq 0\} \) and \( F = \{w \in \mathbb{R}^m : h_j(w) \leq 0\} \). Suppose that \( K_1 = \{x \in \mathbb{R}^n : (x, y) \in K \text{ for some } y \in \mathbb{R}^m\} \) and \( F \) are compact sets. Then, a global minimizer for \( (P) \) exists.

**Proof.** Denote the optimal value of problem \( (P) \) by \( \text{val}(P) \). Let \( (x_k, y_k) \) be a minimizing sequence for the bilevel polynomial optimization problem \( (P) \) in the sense that \( g_i(x_k, y_k) \leq 0, i = 1, \ldots, s, h_j(y_k) \leq 0, j = 1, \ldots, r \), \( y_k \in Y(x_k) \), and \( f(x_k, y_k) \to \text{val}(P) \). Clearly, \( (x_k, y_k) \in K \) (and so, \( x_k \in K_1 \)) and \( y_k \in F \). By passing to a subsequence, we may assume that \( (x_k, y_k) \to (\bar{x}, \bar{y}) \in K_1 \times F \). By continuity, we have \( f(\bar{x}, \bar{y}) = \text{val}(P) \). To see the conclusion, it suffices to show that \( \bar{y} \in Y(\bar{x}) \). Denote \( \epsilon_k = \|x_k - \bar{x}\| \to 0 \). Then, by Theorem 2.3, there is \( c > 0 \) such that
\[
Y(x_k) \subseteq Y(\bar{x}) + c \epsilon_k^2 \mathbb{B}_{\mathbb{R}^m}(0, 1) \quad \text{for all} \quad k \in \mathbb{N}.
\]
As \( y_k \in Y(x_k) \), there exists \( y'_k \in Y(\bar{x}) \) such that
\[
\|y_k - y'_k\| \leq 2c \epsilon_k^2 \to 0.
\]
Note that \( Y(\bar{x}) \subseteq F \), \( Y(\bar{x}) \) is a closed set, and \( F \) is compact. It follows that \( Y(\bar{x}) \) is also a compact set. Passing to the limit in (2.7), we see that \( \bar{y} \in Y(\bar{x}) \). So, a global minimizer for problem \( (P) \) exists.

The following lemma of Putinar [39], which provides a characterization for positivity of a polynomial over a system of polynomial inequalities, can also be regarded as a polynomial analogue of Farkas’ lemma [14]. This lemma has been extensively used in polynomial optimization [26] and plays a key role in the convergence analysis of our proposed method later on.
LEMMA 2.6 (Putinar’s Positivstellensatz [39]). Let \( f_0 \) and \( f_i, i = 1, \ldots, p \), be real polynomials in \( w \) on \( \mathbb{R}^n \). Suppose that there exist \( R > 0 \) and sums-of-squares polynomials \( \sigma_1, \ldots, \sigma_p \in \Sigma^2[w] \) such that \( R - \|w\|^2 = \sigma_0(w) + \sum_{i=1}^p \sigma_if_i(w) \) for all \( w \in \mathbb{R}^n \). If \( f_0(w) > 0 \) over the set \( \{w \in \mathbb{R}^n : f_i(w) \geq 0, i = 1, \ldots, p\} \), then there exist \( \sigma_i \in \Sigma^2[w], i = 0, 1, \ldots, p \) such that \( f_0 = \sigma_0 + \sum_{i=1}^p \sigma_if_i \).

The following assumption plays a key role throughout the paper.

Assumption 2.1. There exist \( R_1, R_2 > 0 \) such that the quadratic polynomials \((x, y) \mapsto R_1 - \|(x, y)\|^2\) and \(y \mapsto R_2 - \|y\|^2\) can be written as

\[
R_1 - \|(x, y)\|^2 = \sigma_0(x, y) - \sum_{i=1}^s \sigma_i(x, y)g_i(x, y)
\]

and

\[
R_2 - \|y\|^2 = \sigma_0(y) - \sum_{j=1}^r \sigma_j(h_j(y))
\]

for some sums-of-squares polynomials \( \sigma_0, \sigma_1, \ldots, \sigma_s \in \Sigma^2[x, y] \) and sums-of-squares polynomials \( \overline{\sigma}_0, \overline{\sigma}_1, \ldots, \overline{\sigma}_r \in \Sigma^2[y] \).

We note that Assumption 2.1 implies that both \( K = \{(x, y) \in \mathbb{R}^n \times \mathbb{R}^m : g_i(x, y) \leq 0, i = 1, \ldots, s\} \) and \( F = \{y \in \mathbb{R}^m : h_j(y) \leq 0, j = 1, \ldots, r\} \) are compact sets [26]. Moreover, Assumption 2.1 can be easily satisfied when \( K \) and \( F \) are nonempty compact sets, and one knows the bounds \( N_1 \) for \( \|x\| \) on \( K \) and \( N_2 \) for \( \|y\| \) on \( F \). Indeed, in this case, it suffices to add redundant constraints \( g_{s+1}(x, y) = \|(x, y)\|^2 - (N_1^2 + N_2^2) \) and \( h_{r+1}(y) = \|y\|^2 - N_2^2 \) to the definition of \( K \) and \( F \), respectively, and Assumption 2.1 is satisfied with \( R_1 = N_1^2 + N_2^2, R_2 = N_2^2, \sigma_i \equiv 0 \) for all \( 1 \leq i \leq s, \overline{\sigma}_j \equiv 0 \) for all \( 1 \leq j \leq r \), and \( \sigma_{s+1} = \overline{\sigma}_{r+1} \equiv 1 \). We also note that, under Assumption 2.1, a solution for problem \((P)\) exists by Corollary 2.5.

3. Convex lower-level problems. In this section, we consider the convex polynomial bilevel programming problem \((P)\) where the lower-level problem is convex in the sense that for each \( x \in \mathbb{R}^n \), \( G(x, \cdot) \) is a convex polynomial, \( h_j \) are polynomials, \( j = 1, \ldots, r \), and the feasible set of lower-level problem \( F := \{w \in \mathbb{R}^m : h_j(w) \leq 0, j = 1, \ldots, r\} \) is a convex set. We note that the representing polynomials \( h_j \) which describe the convex feasible set \( F \) need not be convex, in general.

We say that the lower-level convex problem of \((P)\) satisfies the nondegeneracy condition if for each \( j = 1, \ldots, r \),

\[
y \in F \text{ and } h_j(y) = 0 \Rightarrow \nabla h_j(y) \neq 0.
\]

Recall that the lower level convex problem of \((P)\) is said to satisfy the Slater condition whenever there exists \( y_0 \in \mathbb{R}^m \) such that \( h_j(y_0) < 0 \), \( j = 1, \ldots, r \). Note that under the Slater condition, the lower-level problem automatically satisfies the nondegeneracy condition if each \( h_j \), \( j = 1, \ldots, r \), is a convex polynomial.

Let us recall a lemma which provides a link between a KKT point and a minimizer for a convex optimization problem where the representing function of the convex feasible set is not necessarily convex.

LEMMA 3.1 (see [28, Theorem 2.1]). Let \( \phi \) be a convex function on \( \mathbb{R}^m \) and let \( F := \{w \in \mathbb{R}^m : h_j(w) \leq 0, j = 1, \ldots, r\} \) be a convex set. Suppose that both the nondegeneracy condition and the Slater condition hold. Then, a point \( y \) is a global minimizer of \( \min \{\phi(w) : w \in F\} \) if and only if \( y \) is a KKT point of \( \min \{\phi(w) : w \in F\} \).
in the sense that there exist $\lambda_j \geq 0$, $j = 1, \ldots, r$, such that

$$\nabla \phi(y) + \sum_{j=1}^{r} \lambda_j \nabla h_j(y) = 0, \quad \lambda_j h_j(y) = 0, \quad h_j(y) \leq 0, \quad j = 1, \ldots, r.$$  

We see in the following proposition that a polynomial bilevel programming problem with convex lower-level problem can be equivalently rewritten as a single-level polynomial optimization problem in a higher dimension under the nondegeneracy condition and the Slater condition. In the special case where all the representing polynomials $h_j$ are convex, this lemma has been established in [12].

**Proposition 3.2 (equivalent single-level problem).** Consider problem $(P)$ where the lower level problem is convex. Suppose that the lower level problem satisfies both the nondegeneracy condition and the Slater condition. Then, $(x, y) \in \mathbb{R}^n \times \mathbb{R}^n$ is a global solution of the bilevel polynomial optimization problem $(P)$ if and only if there exist Lagrange multipliers $\lambda = (\lambda_0, \ldots, \lambda_r) \in \mathbb{R}^{r+1}$ such that $(x, y, \lambda) \in \mathbb{R}^n \times \mathbb{R}^m \times \mathbb{R}^{r+1}$ is a global solution of the following single-level polynomial optimization problem:

$$\begin{align*}
(\tilde{P}) \quad \min_{x \in \mathbb{R}^n, y \in \mathbb{R}^m, \lambda \in \mathbb{R}^{r+1}} & \quad f(x, y) \\
\text{subject to} & \quad g_i(x, y) \leq 0, \quad i = 1, \ldots, s, \\
& \quad \lambda_0 \nabla_y G(x, y) + \sum_{j=1}^{r} \lambda_j \nabla h_j(y) = 0, \\
& \quad \lambda_0 \geq 0, \quad \sum_{j=0}^{r} \lambda_j^2 = 1, \quad \lambda_j h_j(y) = 0, \quad \lambda_j \geq 0, \quad h_j(y) \leq 0, \quad j = 1, \ldots, r.
\end{align*}$$

**Proof.** Fix any $x \in \mathbb{R}^n$. The conclusion will follow if we show that $y \in Y(x)$ is equivalent to the condition that there exist $\lambda_j \geq 0$, $j = 0, 1, \ldots, r$, such that

$$\begin{align*}
\lambda_0 \nabla_y G(x, y) + \sum_{j=1}^{r} \lambda_j \nabla h_j(y) & = 0, \\
\lambda_j h_j(y) & = 0, \quad \lambda_j \geq 0, \quad h_j(y) \leq 0, \quad j = 1, \ldots, r, \\
\lambda_0 & \geq 0, \quad \sum_{j=0}^{r} \lambda_j^2 = 1.
\end{align*}$$

(3.2)

To see the equivalence, we first assume that $y \in Y(x)$. Under both the nondegeneracy condition and the Slater condition, the preceding lemma guarantees that there exist $\mu_j \geq 0$, $j = 1, \ldots, r$, such that

$$\nabla_y G(x, y) + \sum_{j=1}^{r} \mu_j \nabla h_j(y) = 0, \quad \mu_j h_j(y) = 0, \quad \mu_j \geq 0, \quad h_j(y) \leq 0, \quad j = 1, \ldots, r.$$  

(3.3)  

So, (3.2) holds with $\lambda_0 = \frac{1}{\sqrt{1 + \sum_{j=1}^{r} \mu_j}}$ and $\lambda_j = \frac{\mu_j}{\sqrt{1 + \sum_{j=1}^{r} \mu_j}}$, $j = 1, \ldots, r$.

Conversely, let $(x, y, \lambda)$ satisfy (3.2). We now show that $\lambda_0 \neq 0$. Indeed, assume on the contrary that $\lambda_0 = 0$. Then, $\sum_{j=1}^{r} \lambda_j^2 = 1$, $\sum_{j=1}^{r} \lambda_j \nabla h_j(y) = 0$, $\lambda_j h_j(y) = 0$,

---

3Indeed, as shown in the proof, $\lambda_0 \neq 0$ always holds under our assumptions. See Remark 3.3 for a detailed discussion.
particular, the equivalence of the following two systems:

$$\lambda_j \geq 0, \text{ and } h_j(y) \leq 0 \text{ for } j = 1, \ldots, r. \text{ Let } J = \{j \in \{1, \ldots, r\} : \lambda_j > 0\} \neq \emptyset. \text{ From the Slater condition, there exists } y_0 \in \mathbb{R}^m \text{ such that } h_j(y_0) < 0, j = 1, \ldots, r. \text{ Then, there exists } \rho > 0 \text{ such that } h_j(w) < 0 \text{ for all } w \in \mathbb{R}^m \text{ with } \|w - y_0\| \leq \rho. \text{ As } \sum_{j=1}^r \lambda_j \nabla h_j(y) = 0, \text{ we obtain}

$$

$$\sum_{j \in J} \lambda_j \nabla h_j(y)^T(w - y) = 0 \text{ for all } w \text{ with } \|w - y_0\| \leq \rho. \tag{3.4}$$

We now see that \( \nabla h_j(y)^T(w - y) \leq 0 \) for all \( w \) with \( \|w - y_0\| \leq \rho \) and for all \( j \in J \). (Suppose on the contrary that there exists \( w_0 \) with \( \|w_0 - y_0\| \leq \rho \) and \( j_0 \in J \) such that \( \nabla h_{j_0}(y)^T(w_0 - y) > 0 \). By continuity, for all small \( t \), \( h_{j_0}(y + t(w_0 - y)) > 0 \), and hence \( y + t(w_0 - y) \not\in F \). On the other hand, from our choice of \( \rho \), we see that \( h_j(w_0) < 0 \) for all \( j = 1, \ldots, r \). So, \( w_0 \in F \). It then follows from the convexity of \( F \) that \( y + t(w_0 - y) \in F \) for all small \( t \). This is impossible.) This together with (3.4) and \( \lambda_j = 0 \) for all \( j \notin J \) shows that

$$\nabla h_j(y)^T(w - y) = 0 \text{ for all } w \text{ with } \|w - y_0\| \leq \rho \text{ and } j \in J,$$

and so \( \nabla h_j(y) = 0 \) for all \( j \in J \). Note that \( y \in F \) and \( h_j(y) = 0 \) for all \( j \in J \). This contradicts the nondegeneracy condition, and so \( \lambda_0 \neq 0 \). Thus, by dividing \( \lambda_0 \) on both sides of the first relation of (3.2), we see that (3.3) holds. This shows that \( y \in Y(x) \) by the preceding lemma again.

Remark 3.3 (importance of nondegeneracy and Slater’s conditions). In Proposition 3.2, we require that the nondegeneracy condition and the Slater condition hold. These assumptions provide us a simple uniform bound for the multipliers \( \lambda_0, \ldots, \lambda_r \) in the lower-level problem which plays an important role in our convergence analysis later in Theorem 3.5. Indeed, these assumptions ensure that \( \lambda_0 \neq 0 \) and so, in particular, the equivalence of the following two systems:

$$\begin{bmatrix}
\lambda_0 \nabla_y G(x, y) + \sum_{j=1}^r \lambda_j \nabla h_j(y) = 0,
\lambda_0 \geq 0, \lambda_j h_j(y) = 0, \lambda_j \geq 0, h_j(y) \leq 0, j = 1, \ldots, r,
\sum_{j=0}^r \lambda_j^2 = 1,
\end{bmatrix}$$

$$\iff$$

$$\begin{bmatrix}
\nabla_y G(x, y) + \sum_{j=1}^r \mu_j \nabla h_j(y) = 0,
\mu_j h_j(y) = 0, \mu_j \geq 0, h_j(y) \leq 0, j = 1, \ldots, r,
\end{bmatrix}.$$

Note that the nondegeneracy condition is satisfied when the representing functions \( h_j, j = 1, \ldots, r \), are convex polynomials and the Slater condition holds. Thus, in this special case, the Slater condition alone is enough for transforming the polynomial bilevel problem with a convex lower-level problem to a single-level polynomial optimization problem.

The following simple example illustrates that the preceding proposition can be applied to the case where \( h_j \)'s need not be convex polynomials.
Example 3.4. Consider the bilevel problem

\[(EP_1) \quad \min_{x \in \mathbb{R}, y \in \mathbb{R}^2} -x^6 + y_1^2 + y_2^2 \]

subject to

\[x^2 + y_1^2 + y_2^2 \leq 2, \quad y \in Y(x) := \arg\min_{w \in \mathbb{R}^2} \{x(w_1 + w_2) : 1 - w_1 w_2 \leq 0, 0 \leq w_1 \leq 1, 0 \leq w_2 \leq 1\}.\]

Clearly, the lower-level problem of \((EP_1)\) is convex but the polynomial \((w_1, w_2) \mapsto 1 - w_1 w_2\) is not convex. It can be verified that the nondegeneracy condition and Slater condition hold, and so, \((EP_1)\) is equivalent to the following single-level polynomial optimization problem:

\[
\min_{x \in \mathbb{R}, y \in \mathbb{R}^2, (\lambda_0, \ldots, \lambda_5) \in \mathbb{R}^6} -x^6 + y_1^2 + y_2^2 \]

subject to

\[x^2 + y_1^2 + y_2^2 \leq 2, \quad 1 - y_1 y_2 \leq 0, 0 \leq y_1 \leq 1, 0 \leq y_2 \leq 1, \]
\[\lambda_0 x + \lambda_1 (-y_2) - \lambda_2 + \lambda_3 = 0, \]
\[\lambda_0 x + \lambda_1 (-y_1) - \lambda_4 + \lambda_5 = 0, \]
\[\lambda_1 (1 - y_1 y_2) = 0, \lambda_2 y_1 = 0, \lambda_3 (1 - y_1) = 0, \]
\[\lambda_4 y_2 = 0, \lambda_5 (1 - y_2) = 0, \]
\[\lambda_j \geq 0, j = 0, 1, \ldots, 5, \sum_{j=0}^{5} \lambda_j^2 = 1.\]

Proposition 3.2 enables us to construct a sequence of SDP problems for solving a polynomial bilevel programming problem with a convex lower-level problem. To do this, we denote

\[
\tilde{G}_p(x, y, \lambda) = \begin{cases} 
  g_p(x, y), & p = 1, \ldots, s, \\
  h_{p-s}(y), & p = s + 1, \ldots, s + r, \\
  -\lambda_{p-(s+r+1)}, & p = s + r + 1, \ldots, s + 2r + 1,
\end{cases}
\]

and

\[
\tilde{H}_q(x, y, \lambda) = \begin{cases} 
  \lambda_q h_q(y), & q = 1, \ldots, r, \\
  \left(\lambda_0 \nabla_y G(x, y) + \sum_{j=1}^{r} \lambda_j \nabla h_j(y)\right)_{q-r}, & q = r + 1, \ldots, r + m, \\
  \sum_{j=0}^{r} \lambda_j^2 - 1, & q = r + m + 1,
\end{cases}
\]

where \((\lambda_0 \nabla_y G(x, y) + \sum_{j=1}^{r} \lambda_j \nabla h_j(y))\) is the \(i\)th coordinate of \(\lambda_0 \nabla_y G(x, y) + \sum_{j=1}^{r} \lambda_j \nabla h_j(y), i = 1, \ldots, m\). We also denote the degree of \(\tilde{G}_p\) to be \(u_p\) and the degree of \(\tilde{H}_q\) to be \(v_q\).
We now introduce a sequence of sums-of-squares relaxation problems as follows: for each $k \in \mathbb{N}$,

\begin{equation}
(Q_k) \max_{\mu, \sigma_p} \mu \\
\text{subject to } f - \mu = \sigma_0 - \sum_{p=1}^{s+2r+1} \sigma_p \hat{G}_p - \sum_{q=1}^{r+m+1} \phi_q \hat{H}_q,
\end{equation}

where

- $\sigma_p \in \Sigma^2[x, y]$, $p = 0, 1, \ldots, s + 2r + 1$,
- $\deg \sigma_0 \leq 2k$, $\deg(\sigma_p \hat{G}_p) \leq 2k, p = 1, \ldots, s + 2r + 1$,
- $\phi_q \in \mathbb{R}[x, y], q = 1, \ldots, r + m + 1$, $\deg(\phi_q \hat{H}_q) \leq 2k, q = 1, \ldots, r + m + 1$.

It is known that each $(Q_k)$ can be reformulated as a SDP problem [26].

**Theorem 3.5 (convex lower-level problem: Convergence theorem).** Consider the problem $(P)$, where the lower-level problem is convex. Suppose that Assumption 2.1 holds and that the lower-level problem satisfies both the nondegeneracy condition and the Slater condition. Then, $\text{val}(Q_k) \leq \text{val}(Q_{k+1})$ for all $k \in \mathbb{N}$ and $\text{val}(Q_k) \to \text{val}(P)$ as $k \to \infty$, where $\text{val}(Q_k)$ and $\text{val}(P)$ denote the optimal value of the problems $(Q_k)$ and $(P)$, respectively.

**Proof.** From Corollary 2.5, a global solution of $(P)$ exists. Let $(x, y)$ be a global solution of $(P)$. From Proposition 3.2, there exists $\lambda \in \mathbb{R}^{r+1}$ such that $(x, y, \lambda)$ is a solution of $(P)$ and $\text{val}(P) = \text{val}(\hat{P})$.

From the construction of $(Q_k)$, $k \in \mathbb{N}$, it can be easily verified that $\text{val}(Q_k) \leq \text{val}(Q_{k+1}) \leq \text{val}(P)$ for all $k \in \mathbb{N}$. Let $\epsilon > 0$. Define $\tilde{f}(x, y, \lambda) = f(x, y) - (\text{val}(P) - \epsilon)$. Note that the feasible set $U$ of $(P)$ can be written as

$$U = \{(x, y, \lambda) \in \mathbb{R}^n \times \mathbb{R}^m \times \mathbb{R}^{r+1} : -\hat{G}_p(x, y, \lambda) \geq 0, p = 1, \ldots, s + 2r + 1,
- \hat{H}_q(x, y, \lambda) \geq 0, q = 1, \ldots, r + m + 1\}.$$

Then, we see that $\tilde{f} > 0$ over $U$. We now verify that the conditions in Putinar's Positivstellensatz (Lemma 2.6) are satisfied. To see this, from Assumption 2.1, there exist $R_1, R_2 > 0$ such that

$$R_1 - \|(x, y)\|^2 = \sigma_0(x, y) - \sum_{i=1}^{s} \sigma_i(x, y)g_i(x, y) \quad \text{and}$$
$$R_2 - \|y\|^2 = \sigma_0(y) - \sum_{j=1}^{r} \tilde{\sigma}_j(y)h_j(y)
$$

for some sums-of-squares polynomials $\sigma_0, \sigma_1, \ldots, \sigma_s \in \Sigma^2[x, y]$ and sums-of-squares polynomials $\sigma_0, \sigma_1, \ldots, \sigma_r \in \Sigma^2[y]$. Letting $\lambda = (\lambda_0, \lambda_1, \ldots, \lambda_r) \in \mathbb{R}^{r+1}$, we obtain
that
\[(1 + R_1 + R_2) - \|(x, y, \lambda)\|^2 = (\sigma_0(x, y) + \bar{\sigma}_0(y)) - \sum_{j=1}^r \sigma_j(y)h_j(y) - \sum_{i=1}^s \sigma_i(x, y)g_i(x, y) + \left(1 - \sum_{j=0}^r \lambda_j^2\right)\]
\[= (\sigma_0(x, y) + \bar{\sigma}_0(y)) - \sum_{j=1}^r \sigma_j(y)\tilde{G}_{s+j}(x, y, \lambda) - \sum_{i=1}^s \sigma_i(x, y)\tilde{G}_i(x, y) - \tilde{H}_{r+m+1}(x, y, \lambda)\]

So, applying Putinar’s Positivstellensatz (Lemma 2.6) with \(w = (x, y, \lambda) \in \mathbb{R}^m \times \mathbb{R}^n \times \mathbb{R}^{r+1}\), there exist sums-of-squares polynomials \(\sigma_p \in \Sigma^2[x, y, \lambda]\), \(p = 0, 1, \ldots, s + 2r + 1\), and sums-of-squares polynomials \(\phi_{1q}, \phi_{2q} \in \Sigma^2[x, y, \lambda]\), \(q = 1, \ldots, r + m + 1\), such that
\[
\hat{f} = \sigma_0 - \sum_{p=1}^{s+2r+1} \sigma_p \tilde{G}_p - \sum_{q=1}^{r+m+1} \phi_{1q} \tilde{H}_q + \sum_{q=1}^{r+m+1} \phi_{2q} \hat{H}_q.
\]
Let \(\phi_q \in \mathbb{R}[x, y, \lambda]\) be a real polynomial defined by \(\phi_q = \phi_{1q} - \phi_{2q}\), \(q = 1, \ldots, r + m + 1\). Then, we have
\[
f - (\text{val}(\mathcal{P}) - \epsilon) = \sigma_0 - \sum_{p=1}^{s+2r+1} \sigma_p \tilde{G}_p - \sum_{q=1}^{r+m+1} \phi_q \hat{H}_q.
\]
Thus, there exists \(k \in \mathbb{N}\), \(\text{val}(Q_k) \geq \text{val}(\mathcal{P}) - \epsilon = \text{val}(P) - \epsilon\). Note that, by the construction, \(\text{val}(Q_k) \leq \text{val}(\mathcal{P}) = \text{val}(P)\) for all \(k \in \mathbb{N}\). Therefore, \(\text{val}(Q_k) \rightarrow \text{val}(\mathcal{P}) = \text{val}(P)\).

Remark 3.6 (convergence to a global minimizer). It is worth noting that in addition to the assumptions of Theorem 3.5, if we further assume that the equivalent problem (\(\mathcal{P}\)) has a unique solution, say, \((\bar{x}, \bar{y})\), then we can also find the global minimizer \((\bar{x}, \bar{y})\) with the help of the above sequential SDP relaxation problems. In fact, as each \((Q_k)\) is an SDP problem, its corresponding dual problem (see [26]) can be formulated as
\[
(Q_k') \inf_{\mathbf{z} \in \mathbb{R}^{n+m+r}} L_\mathbf{z}(f)
\text{subject to } M_k(\mathbf{z}) \succeq 0, \ \mathbf{z}_0 = 1,
M_{k-\mathcal{P}}(\tilde{G}_p, \mathbf{z}) \succeq 0, p = 1, \ldots, s + 2r + 1,
M_{k-\mathcal{P}}(\tilde{H}_q, \mathbf{z}) = 0, q = 1, \ldots, r + m + 1,
\]
where \(\mathcal{P}\) (resp., \(\mathcal{P}\)) is the largest integer which is smaller than \(\frac{n_p}{3}\) (resp., \(\frac{n_p}{2}\)), \(L_\mathbf{z}\) is the Riesz functional defined by \(L_\mathbf{z}(f) = \sum_\alpha f_\alpha z_\alpha\), with \(f(x) = \sum_\alpha f_\alpha x^\alpha\) and, for a polynomial \(f\), \(M_t(f, \mathbf{z})\), \(t \in \mathbb{N}\), is the so-called localization matrix defined by \([M_t(f, \mathbf{z})]_{\alpha, \beta} = \sum_\gamma f_\gamma x^\alpha z^\beta + \gamma\) for all \(\alpha, \beta \in \mathbb{N}_0^{n+m+r}\). From the weak duality, one has \(\text{val}(\mathcal{P}) \geq \text{val}(Q_k') \geq \text{val}(Q_k)\). Thus, the preceding theorem together with \(\text{val}(P) = \text{val}(\mathcal{P})\) implies that \(\text{val}(Q_k') \rightarrow \text{val}(P)\). Moreover, it was shown in [25, Theorem 4.2]
that if the feasible set of the polynomial optimization problem \((\bar{P})\) has a nonempty interior, then there exists a natural number \(N_0\) such that \(\text{val}(Q_k^*) = \text{val}(Q_k)\) for all \(k \geq N_0\).

Let \(z_k\) be a solution of \((Q_k^*)\). Then, as \(k \to \infty\), we have \((L_{z_k}(X_1), \ldots, L_{z_k}(X_n)) \to \bar{x}\), and \((L_{z_k}(X_{n+1}), \ldots, L_{z_k}(X_{n+m})) \to \bar{y}\), where \(X_i\) denotes the polynomial which maps each vector to its \(i\)th coordinate, \(i = 1, \ldots, n + m\). The conclusion follows from [40].

Theorem 3.5 shows that one can use a sequence of SDP problems to approximate the global optimal value of a bilevel polynomial optimization problem with convex lower-level problem. Moreover, under a sufficient rank condition (see [26, Theorem 5.5]), one can check whether finite convergence has occurred, i.e., by testing whether \(\text{val}(Q_{k_0}) = \text{val}(\bar{P})\) for some \(k_0 \in \mathbb{N}\). This rank condition has been implemented in the software GloptiPoly 3 [18] along with a linear algebra procedure to extract global minimizers of a polynomial optimization problem.

We now provide a simple example to illustrate how to use sequential SDP relaxations to solve the bilevel polynomial optimization problems with convex lower-level problem.

**Example 3.7 (solution by sequential SDP relaxations).** Consider the following simple bilevel polynomial optimization problem:

\[
\begin{align*}
\min_{(x,y) \in \mathbb{R}^2} & \quad xy^5 - y^6, \\
x^2 + y^2 & \leq 2, \\
y & \in Y(x) := \text{argmin}_{w \in \mathbb{R}} \{xw : -1 \leq w \leq 1\}.
\end{align*}
\]

Direct verification shows that there are two global solutions \((-1, 1)\) and \((1, -1)\) with global optimal value 2. We note that the lower-level problem is convex and it is equivalent to the following single-level polynomial optimization problem:

\[
\begin{align*}
\min_{(x,y,\lambda_0,\lambda_1,\lambda_2) \in \mathbb{R}^5} & \quad xy^5 - y^6, \\
x^2 + y^2 & \leq 2, \\
\lambda_0 x + \lambda_1 - \lambda_2 & = 0, \\
\lambda_1 & \geq 0, \lambda_1(y - 1) = 0, \lambda_2(-1 - y) = 0, -1 \leq y \leq 1, \\
\lambda_0^2 + \lambda_1^2 + \lambda_2^2 & = 1.
\end{align*}
\]

Solving the converted single-level polynomial optimization problem using GloptiPoly 3, the solver extracted two global solutions \((x, y, \lambda_0, \lambda_1, \lambda_2) = (-1.000, 1.000, 0.7071, 0.7071, 0)\) and \((x, y, \lambda_0, \lambda_1, \lambda_2) = (1.000, -1.000, 0.7071, 0, 0.7071)\) with the true global optimal value \(-2\).

**Remark 3.8 (single-level polynomial problem).** In the case where \((P)\) is a single-level problem, Theorem 3.5 yields the known convergence result of the sequential SDP relaxation scheme (often referred to as the Lasserre hierarchy) for solving single-level polynomial optimization problems [26]. Indeed, consider a (single-level) polynomial optimization problem

\[
(P_0) \quad \min_{x \in \mathbb{R}^n} \{f(x) : g_i(x) \leq 0, i = 1, \ldots, s\}.
\]
Suppose that there exist $R > 0$ and sums of squares polynomial $\sigma_i \in \Sigma_2^2[x]$ such that

$$R - \|x\|^2 = \sigma_0(x) - \sum_{i=1}^s \sigma_i(x)g_i(x).$$

Let $\hat{f}(x, y) = f(x), \hat{g}_i(x, y) = g_i(x), i = 1, \ldots, s$, and $G(x, y) = 0$ for all $(x, y) \in \mathbb{R}^n \times \mathbb{R}$. We note that $\text{val}(P_0)$ equals the optimal value of the following bilevel polynomial optimization problem:

$$\min_{x \in \mathbb{R}^n, y \in \mathbb{R}^m} \hat{f}(x, y)
\text{subject to } \hat{g}_i(x, y) \leq 0, \ i = 1, \ldots, s,$$
$$y \in Y(x) := \arg\min_{w \in \mathbb{R}^m} \{0 : w^2 \leq 1\}.$$

Then, Theorem 3.5 yields that $\text{val}(P_0) = \lim_{k \to \infty} \text{val}(Q_0^k)$, where, for each $k$, the problem $(Q_0^k)$ is given by

$$(Q_0^k) \max_{\mu, \sigma_p} \mu
\text{subject to } f - \mu = \sigma_0 - \sum_{p=1}^s \sigma_p g_p,$$
$$\sigma_p \in \Sigma_2^2[x], \ p = 0, 1, \ldots, s, \ \text{deg} \sigma_0 \leq 2k, \ \text{deg}(\sigma_p g_p) \leq 2k, \ p = 1, \ldots, s.$$

4. Nonconvex lower-level problems. In this section, we examine how to solve a bilevel polynomial optimization problem with a nonconvex lower-level problem toward a global minimizer using SDP hierarchies.

Consider an $\epsilon$-approximation of the general bilevel polynomial problem $(P)$:

$$(P) \min_{(x, y) \in \mathbb{R}^n \times \mathbb{R}^m} f(x, y)
\text{subject to } g_i(x, y) \leq 0, \ i = 1, \ldots, s,$$
$$h_j(y) \leq 0, \ j = 1, \ldots, r,$$
$$G(x, y) - \min_{w \in \mathbb{R}^m} \{G(x, w) : h_j(w) \leq 0, j = 1, \ldots, r\} \leq \epsilon.$$

The above $\epsilon$-approximation problem plays a key role in the so-called value function approach for finding a stationary point of a bilevel programming problems and has been studied and used widely in the literature (for example, see [31, 45]). The main idea of the value function approach is to further approximate the (possibly nonsmooth and nonconvex) function $x \mapsto \min_{w \in \mathbb{R}^m} \{G(x, w) : h_j(w) \leq 0, j = 1, \ldots, r\}$ using smooth functions and asymptotically solve the problem by using smooth local optimization techniques (such as projected gradient method and sequential quadratic programming problem techniques). For instance, [31] use this approach together with the smoothing projected gradient method to solve the bilevel optimization problem, in the case where $g_i$ depends on $x$ only, $\{x \in \mathbb{R}^n : g_i(x) \leq 0\}$ and $\{w \in \mathbb{R}^m : h_j(w) \leq 0\}$ are convex sets. The algorithm only converges to a stationary point of the original problem (in a suitable sense).

We now introduce a general purpose scheme which enables us to solve $(P_\epsilon)$ toward global solutions using SDP hierarchies. The proof techniques for the convergence of this scheme (Theorem 4.6) rely on the joint-marginal method introduced in [27] to
approximate a global solution of a parameterized single-level polynomial optimization problem. Here, following the approach in [27], we extend the scheme and its convergence analysis to the bilevel polynomial optimization setting.

The following known simple lemma shows that the problem \( (P_\epsilon) \) indeed approximates the original bilevel polynomial optimization problem as \( \epsilon \to 0_+ \). To do this, for \( \epsilon, \delta \geq 0 \), recall that \((\bar{x}, \bar{y})\) is called a \( \delta \)-global solution of \((P_\epsilon)\) if \((\bar{x}, \bar{y})\) is feasible for \((P_\epsilon)\) and \( f(\bar{x}, \bar{y}) \leq \val(P_\epsilon) + \delta \), where \( \val(P_\epsilon) \) is the optimal value of \((P_\epsilon)\).

**Lemma 4.1 (approximation lemma [32]).** Suppose that \( K := \{(x, y) \in \mathbb{R}^n \times \mathbb{R}^m : g_i(x, y) \leq 0\} \) and \( F = \{w \in \mathbb{R}^m : h_j(w) \leq 0\} \) are compact. Let \( \epsilon_k \to 0_+ \) and \( \delta_k \to 0_+ \) as \( k \to \infty \). Let \((\bar{x}_k, \bar{y}_k)\) be an \( \delta_k \)-global solution for \((P_{\epsilon_k})\). Then, \( \{(\bar{x}_k, \bar{y}_k)\}_{k \in \mathbb{N}} \) is a bounded sequence and any of its cluster points \((\bar{x}, \bar{y})\) is a solution of the bilevel polynomial optimization problem \((P)\).

The following lemma explains the analytic property of the function \( \epsilon \mapsto \val(P_\epsilon) \) and shows that \( \val(P_\epsilon) \) converges to \( \val(P) \) in the order of \( O(\epsilon^{\frac{1}{q}}) \) as \( \epsilon \to 0_+ \) for some \( q \in \mathbb{N}_{>0} := \mathbb{N} \setminus \{0\} \). The proof relies on some important properties and facts on semialgebraic functions/sets and we delay the proof to Appendix B.

**Lemma 4.2 (analytic property and approximation quality).** Suppose that Assumption 2.1 holds. Let \( I \subseteq \mathbb{R}_+ := [0, +\infty) \) be a finite interval. For each \( \epsilon \in I \), denote the optimal value of \((P_\epsilon)\) by \( \val(P_\epsilon) \):

(i) The one-dimensional function \( \epsilon \mapsto \val(P_\epsilon) \) is a nonincreasing, lower semicontinuous, right-continuous, and semialgebraic function on \( I \). In particular, the function \( \epsilon \mapsto \val(P_\epsilon) \) is continuous over \( I \) except at finitely many points.

(ii) There exist \( q \in \mathbb{N}_{>0}, \epsilon_0 > 0, \) and \( M > 0 \) such that for all \( \epsilon \in (0, \epsilon_0) \)

\[
\val(P_\epsilon) \leq \val(P) \leq \val(P_\epsilon) + M\epsilon^{\frac{1}{q}}.
\]

Now, we present a simple example to illustrate the above lemma. It also implies that, in general, the function \( \epsilon \mapsto \val(P_\epsilon) \) can be a discontinuous semialgebraic function.

**Example 4.3.** Consider the bilevel polynomial optimization problem

\[
(EP) \quad \min_{(x,y) \in \mathbb{R}^2} \ y
\]

subject to \( x^2 \leq 1, \)

\( y \in \arg\min_{w \in \mathbb{R}} \{x^2 + w^2 : w^2(w^2 - 1)^2 \leq 0\}. \)

Note that \( J(x) = \min_{w \in \mathbb{R}} \{x^2 + w^2 : w^2(w^2 - 1)^2 \leq 0\} = x^2. \) Its \( \epsilon \)-approximation problem is

\[
(EP_\epsilon) \quad \min_{(x,y) \in \mathbb{R}^2} \ y
\]

subject to \( x^2 \leq 1, \)

\( y^2(y^2 - 1)^2 \leq 0, \ y^2 \leq \epsilon. \)

It can be verified that

\[
\val(EP_\epsilon) = \begin{cases} 
0 & \text{if } 0 \leq \epsilon < 1, \\
-1 & \text{if } \epsilon \geq 1.
\end{cases}
\]

Therefore the function \( \epsilon \mapsto \val(EP_\epsilon) \) is nonincreasing, lower semicontinuous, right-continuous, and semialgebraic on \([0, +\infty)\). Moreover, it is continuous, on \([0, \epsilon_0]\) for any \( \epsilon_0 < 1 \) and it is discontinuous at \( 1 \).
Solving $\epsilon$-approximation problems via sequential SDP relaxations. Here, we describe how to solve an $\epsilon$-approximation problem via a sequence of SDP relaxation problems. One of the key steps is to construct a sequence of polynomials to approximate the optimal value function of the lower-level problem $x \mapsto \min_{w \in \mathbb{R}^m} \{G(x, w) : h_j(w) \leq 0, j = 1, \ldots, r\}$. In general, the optimal value function of the lower-level problem is merely a continuous function. We now recall a procedure introduced in [27] to approximate this optimal value function by a sequence of polynomials.

Recall that $K = \{x : g_i(x, y) \leq 0, i = 1, \ldots, s\}$. We denote $Pr_1 K = \{x \in \mathbb{R}^n : (x, y) \in K \text{ for some } y \in \mathbb{R}^m\}$. From Assumption 2.1, $K$ is bounded, and so $Pr_1 K$ is also bounded. Let $Pr_1 K \subseteq \Omega := \{x \in \mathbb{R}^n : \|x\|_{\infty} \leq M\}$ for some $M > 0$. Let $\theta_l(x) = x_l^2 - M^2$, $l = 1, \ldots, n$. Then $\Omega = \{x : \theta_l(x) \leq 0, l = 1, \ldots, n\}$. Let $\varphi$ be a probability Borel measure supported on $\Omega$ with uniform distribution on $X$. We note that all the moments of $\varphi$ over $\Omega$ are denoted by $\gamma = (\gamma_\beta)$, $\beta \in \mathbb{N}^n$, defined by

$$\gamma_\beta := \int_\Omega x^\beta d\varphi(x), \ \beta \in \mathbb{N}^n,$$

which can be easily computed (see [27]).

For each $k \in \mathbb{N}$ with $k \geq k_0 := \max\{\lceil \deg f \rceil, \lceil \deg h_j \rceil\}$, set $\mathbb{N}_n^{2k} := \{(\alpha_1, \ldots, \alpha_n) \in \mathbb{N}^n : \sum_{i=1}^n \alpha_i \leq 2k\}$ and consider the optimization problem

$$\max_{\lambda, \sigma_0, \ldots, \sigma_{r+n}} \sum_{\beta \in \mathbb{N}_n^{2k}} \lambda_\beta \gamma_\beta$$

subject to $G(x, y) - \sum_{\beta \in \mathbb{N}_n^{2k}} \lambda_\beta x^\beta = \sigma_0(x, y) - \sum_{j=1}^r \sigma_j(x, y) h_j(y) - \sum_{l=1}^n \sigma_{r+l}(x, y) \theta_l(x)$.

(4.1)

$$\sigma_j \in \Sigma[x, y], \ j = 0, 1, \ldots, r + n,$$

$$\deg \sigma_0 \leq 2k, \ \deg(\sigma_j h_j) \leq 2k, j = 1, \ldots, r, \ \deg(\sigma_{r+l} \theta_l) \leq 2k, l = 1, \ldots, n,$$

which can be reformulated as a problem [27]. Then, for any feasible solution $(\lambda, \sigma_0, \sigma_1, \ldots, \sigma_{r+n})$, the polynomial $x \mapsto J_k(x) := \sum_{\beta \in \mathbb{N}_n^{2k}} \lambda_\beta x^\beta$ is of degree $2k$ and it satisfies, for all $x \in \Omega = \{x : \theta_l(x) \leq 0, l = 1, \ldots, n\} \text{ and } y \in F := \{w : h_j(w) \leq 0, j = 1, \ldots, r\}$,

$$G(x, y) - \sum_{\beta \in \mathbb{N}_n^{2k}} \lambda_\beta x^\beta = \sigma_0(x, y) - \sum_{j=1}^r \sigma_j(x, y) h_j(y) - \sum_{l=1}^n \sigma_{r+l}(x, y) \theta_l(x) \geq 0.$$

So, for every $k \in \mathbb{N}$, $J_k(x) \leq J(x) := \min_{w \in \mathbb{R}^m} \{G(x, w) : h_j(w) \leq 0\}$ for all $x \in \Omega$. Indeed, the next theorem shows that $J_k$ converges to the optimal value function $J$ on $\Omega$, in the $L_1$-norm sense.

Lemma 4.4 (see [27]). Suppose that Assumption 2.1 holds. For each $k \in \mathbb{N}$, let $\rho_k$ be the optimal value of the SDP (4.1). Let $\epsilon_k \to 0$ and let $(\lambda, \sigma_0, \sigma_1, \ldots, \sigma_{r+n})$ be an $\epsilon_k$-solution of (4.1) in the sense that $\sum_{\beta \in \mathbb{N}_n^{2k}} \lambda_\beta \gamma_\beta \geq \rho_k - \epsilon_k$. Define $J_k \in \mathbb{R}_k[x]$ by $J_k(x) = \sum_{\beta \in \mathbb{N}_n^{2k}} \lambda_\beta x^\beta$. Then, we have $J_k(x) \leq J(x)$ for all $x \in \Omega$ and

$$\int_\Omega |J_k(x) - J(x)| d\varphi(x) \to 0 \text{ as } k \to \infty.$$
**Algorithm 4.5** (general scheme).

Step 0: Fix $\epsilon > 0$. Set $k = 1$.

Step 1: Solve the SDP problem (4.1) and obtain the $\frac{1}{k}$-solution $(\lambda_k, \sigma_k)$ of (4.1).

Define $J_k(x) = \sum_{\beta \in \mathbb{N}_2^d} \lambda_k^\beta x^\beta$.

Step 2: Consider the following semialgebraic set:

$$ S_k := \{(x, y) : g_i(x, y) \leq 0, \ i = 1, \ldots, s, h_j(y) \leq 0, \ j = 1, \ldots, r, G(x, y) - J_k(x) \leq \epsilon\}. $$

If $S_k = \emptyset$, then let $k = k + 1$ and return to Step 1. Otherwise, go to Step 3.

Step 3: Solve the following polynomial optimization problem:

$$ (P_k^i) \quad \min_{(x,y) \in \mathbb{R}^n \times \mathbb{R}^m} f(x, y) $$

subject to $g_i(x, y) \leq 0, \ i = 1, \ldots, s,$

$h_j(y) \leq 0, \ j = 1, \ldots, r,$

$G(x, y) - J_k(x) \leq \epsilon.$

Step 4: Let $v_k^i = \min_{1 \leq i \leq k} \text{val}(P^i_k)$. Update $k = k + 1$. Go back to Step 1.

Before we establish the convergence of this procedure, let us comment that the feasibility problem of the semialgebraic set in Step 2 can be tested by a sequence of SDP relaxations via the Positivstellensatz. This was explained in [38] and was implemented in the MATLAB toolbox SOSTOOLS. As explained before, Step 3 can also be accomplished by solving a sequence of SDP relaxations.

Let us show that there exists a finite number $k_0$ such that $S_{k_0} \neq \emptyset$, and so Algorithm 4.5 is well-defined.

**Lemma 4.5.** Let $\epsilon > 0$. Consider the problem $(P_\ell)$ and Algorithm 4.5. Let $K = \{(x, y) : g_i(x, y) \leq 0, \ i = 1, \ldots, s\}$ and $F = \{w : h_j(w) \leq 0, \ j = 1, \ldots, r\}$. Suppose that Assumption 2.1 holds and $\text{cl}(\text{int}(K \cap (\mathbb{R}^n \times F))) = K \cap (\mathbb{R}^n \times F)$. Then, there exists a finite number $k_0$ such that $S_{k_0} \neq \emptyset$ in Step 2 of Algorithm 4.5.

**Proof.** Note from Corollary 2.5 that a global minimizer $(\bar{x}, \bar{y})$ of $(P)$ exists. In particular, the set $D_0 := \{(x, y) \in K \cap (\mathbb{R}^n \times F) : G(x, y) - J(x) < \epsilon\}$ is a nonempty set as $(\bar{x}, \bar{y}) \in D_0$. Noting from our assumption, we have $\text{cl}(\text{int}(K \cap (\mathbb{R}^n \times F))) = K \cap (\mathbb{R}^n \times F)$. This together with the fact that $\{(x, y) : G(x, y) - J(x) < \epsilon\}$ is an open set (as the optimal value function of the lower-level problem $J(x)$ is continuous) gives us that

$$ \bar{D} := \{(x, y) \in \text{int}(K \cap (\mathbb{R}^n \times F)) : G(x, y) - J(x) < \epsilon\} $$

is a nonempty open set. Define $D := \text{Pr}_1 \bar{D} = \{x \in \mathbb{R}^n : (x, y) \in \bar{D} \text{ for some } y \in \mathbb{R}^m\}$. Then, $D$ is also a nonempty open set. Note from Lemma 4.4 that $J_k$ converges to $J$ in the $L^1(\Omega, \varphi)$-norm. Hence $J_k$ converges to $J$ almost everywhere on $\Omega$. As $\varphi(\Omega) < +\infty$, the classical Egorov’s theorem$^2$ implies that there exists a subsequence $l_k$ such that $J_{l_k}$ converges to $J$-almost uniformly on $\Omega$. So, there exists a Borel set $A$ with $\varphi(A) < \frac{\epsilon}{2}$ with $\eta := \varphi(D) > 0$ such that

$$ J_{l_k} \to J \text{ uniformly over } \Omega \setminus A. $$

---

$^2$The Egorov’s theorem [13, Theorem 2.2] states that for a measure space $(\Omega, \varphi)$, let $f_k$ be a sequence of functions on $\Omega$. Suppose that $\Omega$ is of finite $\varphi$-measure and $\{f_k\}$ converges $\varphi$-almost everywhere on $\Omega$ to a limit function $f$. Then, there exists a subsequence $l_k$ such that $f_{l_k}$ converges to $f$ almost uniformly in the sense that for every $\epsilon > 0$, there exists a measurable subset $\bar{A}$ of $\Omega$ such that $\varphi(A) < \epsilon$, and $\{f_{l_k}\}$ converges to $f$ uniformly on the relative complement $\Omega \setminus A$. 
We observe that \((\Omega \setminus A) \cap D \neq \emptyset\) (Otherwise, as \(D \subseteq \text{Pr}_1 K \subseteq \Omega\), we have \(D \subseteq A\). This implies that \(\eta = \varphi(D) \leq \varphi(A) = \eta/2\) which is impossible as \(\eta > 0\). Let \(x_0 \in (\Omega \setminus A) \cap D\). Then, we have \(J_{ik}(x_0) \to J(x_0)\) and there exists \(y_0 \in \mathbb{R}^n\) such that \(y_0 \in F\), \(G(x_0, y_0) - J(x_0) < \epsilon\). In particular, for all \(k\) large, \((x_0, y_0) \in S_{ik}\). Therefore, \(S_{ik} \neq \emptyset\) for all large \(k\), and so, the conclusion follows.

Remark 4.6. The fact that \(L_1\)-convergence implies almost-uniform convergence can also be seen by using Theorem 2.5.1 (\(L_1\)-convergence implies convergence in measure) and Theorem 2.5.3 (convergence in measure implies almost-uniform convergence for a subsequence) of [2, pp. 92–93] without requiring the measure of \(\Omega\) to be finite.

We note that the condition \(\text{"cl}(\text{int}(K \cap (\mathbb{R}^n \times F))) = K \cap (\mathbb{R}^n \times F)\)” holds when \(C := K \cap (\mathbb{R}^n \times F)\) is a finite union of closed convex sets \(C_i\) with int\(C_i \neq \emptyset\). Moreover, if the set \(C\) is of the form \(\{(x, y) \in \mathbb{R}^n \times \mathbb{R}^m : G_i(x, y) \leq 0, i = 1, \ldots, l\}\) for some polynomials \(G_i\), \(i = 1, \ldots, l\) and \(l \in \mathbb{N}\), then the above condition also holds if the commonly used Mangasarian-Fromovitz constraint qualification [34] is satisfied for any \((x, y) \in C\).

We are now ready to state the convergence theorem of the proposed Algorithm 4.5. The proof of it is quite technical and so it is given later in Appendix C.

**Theorem 4.7** (general bilevel problem \((P)\): Convergence theorem). Let \(\epsilon > 0\) and consider problem \((P_k)\). Let \(v_k^\epsilon\) be generated by Algorithm 4.5. Let \(K = \{(x, y) : g_i(x, y) \leq 0, i = 1, \ldots, s\}\) and \(F = \{w : h_j(w) \leq 0, j = 1, \ldots, r\}\). Suppose that Assumption 2.1 holds and \(\text{cl}(\text{int}(K \cap (\mathbb{R}^n \times F))) = K \cap (\mathbb{R}^n \times F)\):

1. \(v_k^\epsilon \to v_\epsilon \) as \(k \to \infty\) where \(\text{val}(P_\epsilon) \leq v_\epsilon \leq \lim_{k \to \infty} \text{val}(P_k)\). In particular, for almost every \(\epsilon\), \(v_k^\epsilon \to \text{val}(P_\epsilon)\) in the sense that for all finite intervals \(I \subseteq \mathbb{R}_+,\)

\[ v_\epsilon = \text{val}(P_\epsilon) \text{ for all } \epsilon \in I \text{ except at finitely many points}. \]

2. There exists \(\epsilon_0 > 0\) such that for all \(\epsilon \in (0, \epsilon_0)\), \(v_k^\epsilon \to \text{val}(P_\epsilon)\) as \(k \to \infty\). Moreover, let \(\delta_k \downarrow 0\). Let \(v_k^\epsilon = \min_{1 \leq i \leq k} \text{val}(P_i^\epsilon) = \text{val}(P_{\epsilon \delta_k})\) and let \((x_k, y_k)\) be a \(\delta_k\)-solution of \((P_{\epsilon \delta_k})\). Then, \(\{(x_k, y_k)\}\) is a bounded sequence and any cluster point \((\tilde{x}, \tilde{y})\) of \((x_k, y_k)\) is a global minimizer of \((P_\epsilon)\) for all \(\epsilon \in (0, \epsilon_0)\).

We now illustrate how our general scheme can lead to solving a bilevel programming problem with a nonconvex lower-level problem toward a global solution. This is done by applying our scheme to a known test problem of the bilevel programming literature.

**Example 4.8** (illustration of our approximation scheme). Consider the following bilevel optimization test problem (for example, see [31, 37]):

\[
\begin{align*}
\min_{(x, y) \in \mathbb{R}^2} & \quad x + y \\
\text{subject to} & \quad x \in [-1, 1], y \in \arg\min_{w \in [-1, 1]} \left\{ \frac{xw^2}{2} - \frac{w^3}{3} \right\}.
\end{align*}
\]

Let \(Y(x) := \arg\min_{w \in [-1, 1]} \left\{ \frac{xw^2}{2} - \frac{w^3}{3} \right\}\). Clearly, the lower-level problem is nonconvex and all the conditions in Theorem 4.7 are satisfied. The optimal value function of the lower-level problem is given by

\[
J(x) = \min_{w \in [-1, 1]} \left\{ \frac{xw^2}{2} - \frac{w^3}{3} \right\} = \begin{cases} 0 & \text{if } x \in \left[\frac{3}{4}, 1\right], \\ \frac{x}{2} - \frac{1}{3} & \text{if } x \in \left[-1, \frac{3}{4}\right], \\ \end{cases}
\]
and the solution set of the lower-level problem $Y(x)$ can be formulated as

$$Y(x) = \begin{cases} 
\{0\} & \text{if } x \in (\frac{2}{3}, 1], \\
\{0, 1\} & \text{if } x = \frac{2}{3}, \\
\{1\} & \text{if } x \in [-1, \frac{2}{3}).
\end{cases}$$

It is easy to check that the true (unique) global minimizer is $(\bar{x}, \bar{y}) = (-1, 1)^T$ and the true global optimal value is 0.

Now, for $k = 3$, using GloptiPoly 3, we obtain a degree $2k (= 6)$ polynomial approximation of $J(x)$ which is

$$J_3(x) = -0.3338 + 0.5011 \times x + 0.0098 \times x^2 - 0.0032 \times x^3 - 0.0696 \times x^4 - 0.1012 \times x^5 - 0.0432 \times x^6.$$  

Figure 1 depicts the graph of the functions $J_3$ and $J$, where the red curve is the graph of the function $J$ and the blue curve is the graph of the degree 6 polynomial $J_3$. From the graph, we can see that $J_3 \leq J$ over the interval $[-1, 1]$ and provides a reasonably good approximation of the piecewise differentiable (and so nonpolynomial) function $J(x)$.

Setting $\epsilon = 0.001$ and solving the polynomial optimization problem

$$\min_{(x,y)\in\mathbb{R}^2} x + y$$

subject to $x \in [-1, 1]$, 

$$y \in [-1, 1],$$

$$\frac{xy^2}{2} - \frac{y^3}{3} - J_3(x) \leq 0.001,$$

with GloptiPoly 3, the solver returns the point $(x, y) = (-1.0000, 0.9996)$ with its associated function value $-4.1680e - 04$, which is a reasonably good approximation.
of the true global minimizer and global optimal value of the bilevel programming problem.

**Remark 4.9** (further extensions of the approach). Although we presented our approach for a class of bilevel problems where the constraints of the lower-level problem are independent of the upper-level decision variable $x$, our approach may be extended to solve the following more general bilevel polynomial optimization problem:

$$
\text{(GP)} \quad \begin{array}{rl}
\min_{x \in \mathbb{R}^n, y \in \mathbb{R}^m} & f(x, y) \\
\text{subject to} & g_i(x, y) \leq 0, \quad i = 1, \ldots, s, \\
& y \in Y(x) := \arg\min_{w \in \mathbb{R}^m} \{ G(x, w) : h_j(x, w) \leq 0, j = 1, \ldots, r \},
\end{array}
$$

where the constraints of the lower-level problem are allowed to depend on $x$. In this case, we can construct a sequence of SDP relaxation for finding a global minimizer and a global minimum of its $\epsilon$-approximation problem and similar convergence results of the scheme can be achieved under an additional technical assumption that the optimal value function of the lower-level problem $J(x) := \min_{w \in \mathbb{R}^m} \{ G(x, w) : h_j(x, w) \leq 0, j = 1, \ldots, r \}$ is continuous. However, we wish to note that for the problem (P) discussed in this paper (that is, $h_j$ are independent of $x$), this condition is automatically satisfied. On the other hand, in general, this condition may fail for the general problem (GP) even when $n = m = 1$. We provide a simple example to illustrate this. Consider the following bilevel programming problem:

$$
\begin{array}{rl}
\min_{x \in \mathbb{R}, y \in \mathbb{R}} & x^2 + y^2 \\
\text{subject to} & 0 \leq x \leq 1, \\
& y \in Y(x) := \arg\min_{w \in \mathbb{R}} \{ (x - w)^2 : x^2 - w^2 \leq 0, \\
& \quad w(w - 1) \leq 0, -w(w - 1) \leq 0 \}.
\end{array}
$$

It can be directly verified that the optimal value function of the lower-level problem is given by

$$
J(x) := \min_{w \in \mathbb{R}} \{ (x - w)^2 : x^2 - w^2 \leq 0, w(w - 1) = 0 \} = \begin{cases} 
0 & \text{if } x = 0, \\
(x - 1)^2 & \text{if } x \in (0, 1]
\end{cases}
$$

and is discontinuous at $x = 0$.

**5. Numerical examples.** In this section, we apply our schemes to solve some bilevel optimization test problems available in the literature and present their results. We conducted the numerical tests on a computer with a 2.8-GHz Intel Core i7 and 8 GB RAM, equipped with MATLAB 7.14 (R2012a). We solved bilevel polynomial problems with convex as well as nonconvex lower-level problems, where the lower-level problems are independent of the upper-level decision variables.

We first present results for the following bilevel problems with a convex lower-level problem. We note that all the assumptions of Theorem 3.5 are satisfied by these bilevel problems with a convex lower-level problem.

**Example 5.1.** Consider the following bilevel polynomial problem [16]:

\[
\begin{align*}
\min_{x,y \in \mathbb{R}} & \quad (x - 3)^2 + (y - 2)^2 \\
\text{subject to} & \quad -2x + y - 1 \leq 0, \\
& \quad x - 2y + 2 \leq 0, \\
& \quad x + 2y - 14 \leq 0, \\
& \quad 0 \leq x \leq 8, \\
& \quad 0 \leq y \leq 10, \\
& \quad y \in \text{argmin}_{w \in \mathbb{R}} \{ (w - 5)^2 : w \in [0, 10] \}.
\end{align*}
\]

This problem has a unique global minimizer \((x^*, y^*) = (3, 5)\) and the optimal value \(f^* = 9\).

**Example 5.2.** Consider the following bilevel polynomial problem [16]:

\[
\begin{align*}
\min_{x,y \in \mathbb{R}} & \quad -(4x - 3)y + (2x + 1) \\
\text{subject to} & \quad 0 \leq x \leq 1, \\
& \quad 0 \leq y \leq 1, \\
& \quad y \in \text{argmin}_{w \in \mathbb{R}} \{ -(1 - 4x)w - (2x + 2) : w \in [0, 1] \}.
\end{align*}
\]

This problem has a unique global minimizer \((x^*, y^*) = (0.25, 0)\) and the optimal value \(f^* = 1.5\).

We first transformed the problems in Examples 5.1 and 5.2 into equivalent single-level nonconvex polynomial optimization problems as proposed in section 3. Then, we used GloptiPoly 3 [18] and the SDP solver Sedumi [42] to solve the transformed polynomial optimization problems. For these two problems, the second relaxation problem (that is, problem \((Q_2)\)) of the SDP approximation scheme (3.12) returns a solution which agrees with the true solution.

Table 1 summarizes the results of bilevel problems with a convex lower-level problem where \((x^*, y^*)\) and \(f^*\) denote the true global minimizer and the true optimal value, respectively, \((x, y)\) and \(f\) denote the computed minimizer and the computed optimal value, respectively, and CPU time represents the CPU time (in seconds) used to solve the problems.

We now solve the following bilevel problems with a nonconvex lower-level problem. Again, all the assumptions in Theorem 4.7 are satisfied by these bilevel problems with a nonconvex lower-level problem.

**Example 5.3.** Consider the following bilevel polynomial problem [36]:

\[
\begin{align*}
\min_{x,y \in \mathbb{R}} & \quad x \\
\text{subject to} & \quad -x + y \leq 0, \\
& \quad -10 \leq x \leq 10, \\
& \quad -1 \leq y \leq 1, \\
& \quad y \in \text{argmin}_{w \in \mathbb{R}} \{ w^3 : w \in [-1, 1] \}.
\end{align*}
\]
This problem has a unique global minimizer \((x^*, y^*) = (-1, -1)\) with the optimal value \(f^* = -1\).

**Example 5.4.** Consider the following bilevel polynomial problem [36]:

\[
\begin{cases}
\min_{x, y \in \mathbb{R}} & 2x + y \\
\text{subject to} & -1 \leq x \leq 1, \\
& -1 \leq y \leq 1, \\
& y \in \arg\min_{w \in \mathbb{R}} \left\{ \frac{1}{2} x w^2 - \frac{1}{4} w^4 : w \in [-1, 1] \right\}.
\end{cases}
\]

This problem has two global minimizers \((x^*_1, y^*_1) = (-1, 0)\) and \((x^*_2, y^*_2) = (-1/2, -1)\) with the optimal value \(f^* = -2\).

**Example 5.5.** Consider the following bilevel polynomial problem [36]:

\[
\begin{cases}
\min_{x, y \in \mathbb{R}} & y \\
\text{subject to} & 0.1 \leq x \leq 1, \\
& -1 \leq y \leq 1, \\
& y \in \arg\min_{w \in \mathbb{R}} \left\{ x \left( 16w^4 + 2w^3 + 8w^2 + \frac{3}{2}w + \frac{1}{2} \right) : w \in [-1, 1] \right\}.
\end{cases}
\]

This problem has infinitely many global minimizers \((x^*_i, y^*_i) = (a, 0.5)\) for any \(a \in [0.1, 1]\) with the optimal value \(f^* = 0.5\).

**Example 5.6.** Consider the following bilevel polynomial problem [36]:

\[
\begin{cases}
\min_{x, y \in \mathbb{R}} & -x + xy + 10y^2 \\
\text{subject to} & -1 \leq x \leq 1, \\
& -1 \leq y \leq 1, \\
& y \in \arg\min_{w \in \mathbb{R}} \left\{ -x w^2 + w^4/2 : w \in [-1, 1] \right\}.
\end{cases}
\]

This problem has a unique global minimizer \((x^*, y^*) = (0, 0)\) with the optimal value \(f^* = 0\).

We solved these four problems by using the approximation scheme proposed in section 4 implemented via the software GloptiPoly 3 and the SDP solver Sedumi. For a detailed illustration of how the scheme is implemented, see Example 4.8. The numerical results are summarized in Table 2. Note that deg denotes the maximum degree of the polynomial underestimation used in a subproblem of our scheme.

**6. Conclusion and further research.** We established that a global minimizer and the global minimum of a bilevel polynomial optimization problem can be found by way of solving a sequence of SDP relaxations. We first considered a bilevel polynomial optimization problem where the lower-level problem is a convex problem. In this case, we proved that the values of the sequence of relaxation problems converge to the global optimal value of the bilevel problem under a mild assumption. This shows that a global solution can simply be found by first transforming the bilevel problem into an equivalent single-level polynomial problem and then solving the resulting single-level problem by the standard sequential SDP relaxations used in the polynomial optimization [26].

We then examined a general bilevel polynomial optimization problem with a not necessarily convex lower-level problem. We established that the global optimal value in this case can be found by way of solving a new sequential SDP relaxation problem based on the joint-marginal approach proposed in [27]. This was done by using
a sequence of SDP relaxations of its \( \epsilon \)-approximation problem under the standard Assumption 2.1 of polynomial optimization, where \( \epsilon > 0 \) is smaller than a positive threshold.

The convergence of the proposed SDP approximation scheme relies on Assumption 2.1, which requires that the feasible set of the bilevel problem is bounded. The proposed scheme can also be extended to cover possible unbounded feasible sets by exploiting coercivity of the objective function of the upper-/lower-level problem as in our recent papers [21, 22, 23], where the convergence of the sequence of SDP relaxations was established for polynomial optimization problems with unbounded feasible sets.

Our bilevel problem, in the present paper, represents the so-called optimistic approach to the leader and follower’s game in which the follower is assumed to be cooperative and so the leader can choose the solution with the lowest cost. The pessimistic approach assumes that the follower may not be cooperative and hence the leader will need to prepare for the worst cost. Mathematically, the following bilevel problem represents the pessimistic approach:

\[
\min_{x \in \mathbb{R}^n} \max_{y \in Y(x)} f(x, y)
\]

subject to \( g_i(x) \leq 0, \ i = 1, \ldots, s, \)

where \( Y(x) := \arg\min_{w \in \mathbb{R}^m} \{G(x, w) : h_j(w) \leq 0, j = 1, \ldots, r\} \). A possible method for solving this bilevel problem is to construct a polynomial approximation for the optimal value of the problem \( x \mapsto \max_{y \in Y(x)} f(x, y) \) using the joint-marginal approach of [27] and then design an SDP approximation method that is similar to the scheme studied in the present paper. This would be an interesting topic for future research.

Appendix A: Semialgebraic functions and sets. In this appendix, we summarize some of the important properties of semialgebraic functions which are used in this paper (see [5]).

(i) Finite union (resp., intersection) of semialgebraic sets is semialgebraic. The Cartesian product (resp., complement, closure) of semialgebraic sets is semialgebraic.
(ii) If $f, g$ are semialgebraic functions on $\mathbb{R}^n$ and $\lambda \in \mathbb{R}$, then $f + g, fg,$ and $\lambda f$ are all semialgebraic functions.

(iii) If $f$ is a semialgebraic function on $\mathbb{R}^n$ and $\lambda \in \mathbb{R}$, then $\{x : f(x) \leq \lambda\}$ (resp., $\{x : f(x) < \lambda\}$, and $\{x : f(x) = \lambda\}$) are all semialgebraic sets.

(iv) A composition of semialgebraic maps is a semialgebraic map.

(v) The image and inverse image of a semialgebraic set under a semialgebraic map are semialgebraic sets. In particular, the projection of a semialgebraic set is still a semialgebraic set.

(vi) If $S$ is a compact semialgebraic set in $\mathbb{R}^m$ and $f : \mathbb{R}^n \times \mathbb{R}^m \to \mathbb{R}$ is a real polynomial, then the function $x \mapsto \min_{y \in \mathbb{R}^m} \{f(x, y) : y \in S\}$ is also semialgebraic.

**Remark 6.1.** If $A, B \subseteq \mathbb{R}^n$, $B \subseteq \mathbb{R}^m$, and $S \subseteq \mathbb{R}^n \times \mathbb{R}^m$ are semialgebraic sets, then we see that $U := \{x \in A : (x, y) \in S \forall y \in B\}$ is also a semialgebraic set. To see this, from property (v), we see that $\{x \in A : \exists y \in B, (x, y) \in S\}$ is semialgebraic. As the complement of $U$ is the union of the complement of $A$ and the set $\{x \in A : \exists y \in B, (x, y) \notin S\}$, it follows that the complement of $U$ is semialgebraic by property (i). Thus, $U$ is also semialgebraic by property (i). In general, if we have a finite collection of semialgebraic sets, then any set obtained from them by a finite chain of quantifiers is also semialgebraic.

For a one-dimensional semialgebraic function, we have further the following properties.

**Lemma 6.2 (monotonicity theorem [15]).** Let $f$ be a semialgebraic function $f$ on $\mathbb{R}$. Let $a, b \in \mathbb{R}$ with $a < b$. Then, there exists a finite subdivision $a = t_0 < t_1 < \cdots < t_k = b$ such that, on each interval $(t_i, t_{i+1})$, $f$ is continuous and $f$ either takes a constant value or is strictly monotone.

**Lemma 6.3 (growth dichotomy lemma [35]).** Let $\epsilon_0 > 0$ and let $f$ be a continuous semialgebraic function $f$ on $[0, \epsilon_0]$ with $f(0) = 0$. Then either $f$ takes a constant value 0 over $[0, \epsilon_0]$ or there exist constants $c \neq 0$ and $p, q \in \mathbb{N}_{>0}$ such that $f(t) = ct^p + o(t^q)$ as $t \to 0^+$.

**Appendix B: Proof of Lemma 4.2.**

**Proof of (i).** From the definition of $(P_\epsilon)$, it is clear that if $0 \leq \epsilon_1 \leq \epsilon_2$, then $\text{val}(P_{\epsilon_2}) \geq \text{val}(P_{\epsilon_1})$. Using a similar method of proof as in Lemma 4.1, one can show that $\epsilon \mapsto \text{val}(P_{\epsilon})$ is a lower semicontinuous function. Now, let $\epsilon_k \to \epsilon_+$. Then, from the lower semicontinuity,$$
\liminf_{k \to \infty} \text{val}(P_{\epsilon_k}) \geq \text{val}(P_{\epsilon}).
$$This together with the fact that $\epsilon \mapsto \text{val}(P_{\epsilon})$ is nonincreasing shows that $\lim_{k \to \infty} \text{val}(P_{\epsilon_k}) = (P_{\epsilon})$. So, this function is right continuous.

Let $J(x) := \min_{w \in \mathbb{R}} \{G(x, w) : h_j(w) \leq 0, j = 1, \ldots, r\}$. By property (vi), $J$ is a semialgebraic function. Let

$$X := \{(\epsilon, x, y) \in [0, +\infty) \times \mathbb{R}^n \times \mathbb{R}^m : g_i(x, y) \leq 0, i = 1, \ldots, s, h_j(y) \leq 0, j = 1, \ldots, r, G(x, y) - J(x) \leq \epsilon\}$$

and

$$Y := \{(\epsilon, x, y) \in X : f(x, y) \leq f(a, b) \text{ for all } (\epsilon, a, b) \in X\}.$$
We can verify that $X$ and $Y$ are semialgebraic sets by properties (ii) and (iii) and Remark 6.1. Further, by definition, the graph of the function $\epsilon \mapsto \text{val}(P_\epsilon)$ is given by $\{(\epsilon, f(x, y)) : (\epsilon, x, y) \in Y\}$. Clearly, this set is the image of the set $Y$ under the semialgebraic map $(\epsilon, x, y) \mapsto (\epsilon, f(x, y))$, and hence it is a semialgebraic set by property (v). Thus, $\epsilon \mapsto \text{val}(P_\epsilon)$ is a semi-algebraic function on $[0, +\infty)$.

Fix a finite interval $I \subseteq [0, +\infty)$. As $\epsilon \mapsto \text{val}(P_\epsilon)$ is a semialgebraic function, it follows from Lemma 6.2 that the function $\epsilon \mapsto \text{val}(P_\epsilon)$ is continuous over $I$ except at finitely many points.

**Proof of (ii).** Fix a finite interval $I \subseteq [0, +\infty)$. Denote the discontinuity points of $\epsilon \mapsto \text{val}(P_\epsilon)$ on $I$ by $\{\epsilon_1, \ldots, \epsilon_l\}$ for some $l \in \mathbb{N}$. Clearly, $\inf_{1 \leq i \leq l} \epsilon_i > 0$ as $\epsilon \mapsto \text{val}(P_\epsilon)$ is right continuous. Let $\bar{\epsilon} = \min_{1 \leq i \leq l} \{\epsilon_i\}/2 > 0$. Then, $\epsilon \mapsto \text{val}(P_\epsilon)$ is continuous over $[0, \bar{\epsilon}]$. Applying Lemma 6.3 with $f$ replaced by $\epsilon \mapsto \text{val}(P_\epsilon) - \text{val}(P)$ on $[0, \bar{\epsilon}]$, we see that there exist constants $c > 0$, $p, q \in \mathbb{N}$, and $\epsilon_0 \in (0, 1)$ with $\epsilon_0 < \bar{\epsilon}$ such that

$$\begin{align*}
(B.1) \quad \text{val}(P_\epsilon) \leq \text{val}(P) + c \epsilon^{\frac{p}{2}} \leq \text{val}(P) + c \epsilon^{\frac{q}{2}}, \quad \text{for all } \epsilon \in [0, \epsilon_0],
\end{align*}$$

where the last inequality holds as $0 < \epsilon < \epsilon_0 < 1$. This, together with the nonincreasing property of $\epsilon \mapsto \text{val}(P_\epsilon)$, yields the last assertion.

**Appendix C: Proof of Theorem 4.7 (convergence of Algorithm 4.5).**

**Proof of (i).** Recall from Lemma 4.4 that $J_k(x) \leq J(x)$ for all $k \in \mathbb{N}$ and for all $x \in \Omega$. So, $\text{val}(P_k^m) \geq \text{val}(P_\epsilon)$ for all $k \in \mathbb{N}$. This implies that $v_k^m \geq \text{val}(P_\epsilon)$ for all $k \in \mathbb{N}$. As $v_k^m$ is a nonincreasing sequence which is bounded below, $\lim_{k \to \infty} v_k^m$ exists. Let $v_\epsilon = \lim_{k \to \infty} v_k^m$. Then,

$$\begin{align*}
(C.1) \quad v_\epsilon \geq \text{val}(P_\epsilon).
\end{align*}$$

Let $\delta \in (0, \epsilon)$ and consider problem $(P_{\epsilon-\delta})$. By Assumption 2.1, $K$ and $F$ are compact sets. From the nonsmooth Danskin theorem (see [8, p. 86]), we see that the optimal value function of the lower-level problem $J(x) := \min_{w \in \mathbb{R}^n} \{G(x, w) : h_j(w) \leq 0, j = 1, \ldots, r\}$ is locally Lipschitz (and so is continuous). Thus, a global minimizer of $(P_{\epsilon-\delta})$ exists. Let $(\bar{x}, \bar{y})$ be a global minimizer of $(P_{\epsilon-\delta})$. The set $D_\delta := \{(x, y) \in K \cap (\mathbb{R}^n \times F) : G(x, y) - J(x) < \epsilon, f(x, y) < f(\bar{x}, \bar{y}) + \delta\}$ is a nonempty set as $(\bar{x}, \bar{y}) \in D_\delta$. Moreover, from our assumption we have $\partial(\text{int}(K \cap (\mathbb{R}^n \times F))) = K \cap (\mathbb{R}^n \times F)$. This together with the fact that $\{(x, y) : G(x, y) - J(x) < \epsilon, f(x, y) < f(\bar{x}, \bar{y}) + \delta\}$ is an open set gives us that

$$\begin{align*}
D := \{(x, y) \in \text{int}(K \cap (\mathbb{R}^n \times F)) : G(x, y) - J(x) < \epsilon \text{ and } f(x, y) < f(\bar{x}, \bar{y}) + \delta\}
\end{align*}$$

is a nonempty open set. So, $D := \text{Pr}_1 \bar{D} = \{x \in \mathbb{R}^n : (x, y) \in \bar{D} \text{ for some } y \in \mathbb{R}^n\}$ is also a nonempty open set. Since $J_k$ converges to $J$ in the $L^1(\Omega, \varphi)$-norm, $J_k$ converges to $J$ on $\Omega$ almost everywhere. Moreover, as $\varphi(\Omega) < +\infty$, the classical Egorov’s theorem guarantees that there exists a subsequence $k_l$ such that $J_{k_l}$ converges to $J$ $\varphi$-almost uniformly on $\Omega$. So, there exists a Borel set $A$ with $\varphi(A) < \frac{\varphi(\Omega)}{2}$ with $\eta := \varphi(D) > 0$ such that $J_{k_l} \to J$ uniformly over $\Omega \setminus A$. As in the proof of Lemma 4.5, we can show that $(\Omega \setminus A) \cap D \neq \emptyset$. Let $x_0 \in (\Omega \setminus A) \cap D$. Then, we have $J_{k_l}(x_0) \to J(x_0)$ and there exists $y_0 \in F$ such that $G(x_0, y_0) - J(x_0) < \epsilon$ and $f(x_0, y_0) < f(\bar{x}, \bar{y}) + \delta$. So, for all large $k$, $G(x_0, y_0) - J_{k_l}(x_0) < \epsilon$. Thus, for all large $k$, $(x_0, y_0)$ is feasible for $(P_{\epsilon-\delta})$ and

$$\begin{align*}
v_{k_l}^m \leq \text{val}(P_{k_l}^m) \leq f(x_0, y_0) < f(\bar{x}, \bar{y}) + \delta = \text{val}(P_{\epsilon-\delta}) + \delta.
\end{align*}$$
Letting $k \to \infty$, we obtain that $v_\epsilon = \lim_{k \to \infty} v_{\epsilon k}^i \leq \text{val}(P_{\epsilon - \delta}) + \delta$. Letting $\delta \to 0^+$, we see that

$$v_\epsilon \leq \lim_{\delta \to 0^+} \text{val}(P_\delta).$$

Therefore, the inequality $\text{val}(P_\epsilon) \leq v_\epsilon \leq \lim_{\delta \to 0^+} \text{val}(P_\delta)$ follows by combining (C. 1) and (C. 2). To see the second assertion in (i), we only need to notice from Lemma 4.2(ii) that $\epsilon \mapsto \text{val}(P_\epsilon)$ is continuous except finitely many points over a finite interval $I$.

**Proof of (ii).** From Lemma 4.2(ii), we see that there exists $\epsilon_0 > 0$ such that $\epsilon \mapsto \text{val}(P_\epsilon)$ is continuous over $(0, \epsilon_0)$. Thus, from (i), we have $v_{\epsilon k}^i \to \text{val}(P_i)$ for all $\epsilon \in (0, \epsilon_0)$. Now, fix any $\epsilon \in (0, \epsilon_0)$, Let $\delta_k \downarrow 0$ as $k \to \infty$. Let $v_{\epsilon k}^i = \min_{1 \leq i \leq k} \text{val}(P_{\epsilon k}^i)$ and let $(x_k, y_k)$ be a $\delta_k$-solution of $(P_{\epsilon k}^i)$. Then, $\{(x_k, y_k)\} \subseteq K \cap (R^n \times F)$. 

As $K$ and $F$ are compact, we see that $\{(x_k, y_k)\}$ is a bounded sequence. Let $(\tilde{x}, \tilde{y})$ be a cluster point of $\{(x_k, y_k)\}$. Clearly, $(\tilde{x}, \tilde{y}) \in K \cap (R^n \times F)$. As $J_k \leq J$ on $\Omega$ for all $k \in N$, $x_k \in P_1 K \subseteq \Omega$ and $(x_k, y_k)$ is feasible for $(P_{\epsilon k})$. Hence, for each $k \in N$

$$G(x_k, y_k) - J(x_k) \leq G(x_k, y_k) - J_{\epsilon k}(x_k) \leq \epsilon.$$

Passing to the limit and noting that $J$ is continuous, we get that $G(\tilde{x}, \tilde{y}) - J(\tilde{x}) \leq \epsilon$. So, $(\tilde{x}, \tilde{y})$ is feasible for $(P_\epsilon)$. Finally, since $v_{\epsilon k}^i \to \text{val}(P_i)$, it follows that

$$f(\tilde{x}, \tilde{y}) = \lim_{k \to \infty} f(x_k, y_k) \leq \lim_{k \to \infty} (v_{\epsilon k}^i + \delta_k) = \text{val}(P_\epsilon)$$

and $(\tilde{x}, \tilde{y})$ is a global minimizer of $(P_\epsilon)$.
