Abstract

In this work, we propose an algorithm to price American options by directly solving the dual minimization problem introduced by Rogers [2002]. Our approach relies on approximating the set of uniformly square integrable martingales by a finite dimensional Wiener chaos expansion. Then, we use a sample average approximation technique to efficiently solve the optimization problem. Unlike all the regression based methods, our method can transparently deal with path dependent options without extra computations and a parallel implementation writes easily with very little communication and no centralized work. We test our approach on several multi-dimensional options with up to 40 assets and show the impressive scalability of the parallel implementation.

Key words: American option, duality, Snell envelope, stochastic optimization, sample average approximation, high performance computing, Wiener chaos expansion.

AMS subject classification: 62L20, 62L15, 91G60, 65Y05, 60H07

1 Introduction

The pricing of American options quickly becomes challenging as the dimension increases and the payoff gets complex. Many people have contributed to this problem usually by considering its dynamic programming principle formulation [Tilley 1993, Carriere 1996, Tsitsiklis and Roy 2001, Longstaff and Schwartz 2001, Broadie and Glasserman 2004 and Bally and Pages 2003]. Among this so extensive literature, the practitioners seem to prefer the iterative optimal policy approach proposed by Longstaff and Schwartz [2001], which proves to be quite efficient in many situations. However, true path–dependent options cannot be handled by this approach. Solving the dynamic programming principle requires the computation of a conditional expectation, which is eventually dealt with regression

The High Performance Computations presented in this paper were performed using the Froggy platform of the CIMENT infrastructure (https://ciment.ujf-grenoble.fr), which is supported by the Rhône-Alpes region (GRANT CPER07_13 CIRA) and the Equip@Meso project (reference ANR-10-EQPX-29-01) of the programme Investissements d’Avenir supervised by the Agence Nationale pour la Recherche.
techniques. These techniques are known to suffer from the curse of dimensionality: global regression methods lead to high dimensional linear algebra problems, whereas local methods see the number of domains blow up with the dimension. Despite the numerous parallel implementation of this techniques (see for instance Dung Doan et al. [2010], Abbas-Turki et al. [2014]), we cannot expect to obtain a fully scalable algorithm. In this work, we follow the dual approach initiated by Rogers [2002], and Davis and Karatzas [1994], which can naturally handle path dependent options. To make it implementable, we need a smart and finite dimensional approximation of the set of uniformly integrable martingales. We chose the set of truncated Wiener chaos expansions, which have some magic features in our problem: its density makes the optimization differentiable almost everywhere and computing its conditional expectation exactly is straightforward. Then, the pricing problem boils down to a finite dimensional and convex optimization problem. The optimization problem is solved using a Sample Average Approximation (see Rubinstein and Shapiro [1993]), which can be easily and efficiently implemented using parallel computing.

We fix some finite time horizon \( T > 0 \) and a filtered probability space \((\Omega, \mathcal{F}, (\mathcal{F}_t)_{0 \leq t \leq T}, \mathbb{P})\), where \((\mathcal{F}_t)_{0 \leq t \leq T}\) is supposed to be the natural augmented filtration of a \(d\)-dimensional Brownian motion \(B\). On this space, we consider an adapted process \((S_t)_{0 \leq t \leq T}\) with values in \(\mathbb{R}^{d'}\) modeling a \(d'\)-dimensional underlying asset. The number of assets \(d'\) can be smaller than the dimension \(d\) of the Brownian motion to encompass the case of stochastic volatility models or stochastic interest rate. We assume that the short interest rate is modelled by an adapted process \((r_t)_{0 \leq t \leq T}\) with values in \(\mathbb{R}_+\) and that \(\mathbb{P}\) is an associated risk neutral measure. We consider an adapted payoff process \(\tilde{Z}\) and introduce its discounted value process \(Z_t = e^{-\int_0^t r_s \, ds} \tilde{Z}_t\) \(0 \leq t \leq T\). We assume that the paths of \(Z\) are right continuous and that \(\sup_{t \in [0,T]} |Z_t| \in L^2\). The process \(\tilde{Z}\) can obviously take the simple form \((\phi(S_t))_{t \leq T}\) but it can also depend on the whole path of \(S\) up to the current time. So, our framework transparently deals with path-dependent option, which are far more difficult to handle using regression techniques.

We consider the American option paying \(\tilde{Z}_t\) to its holder if exercised at time \(t\). Standard arbitrage pricing theory defines the discounted time-\(t\) value of the American option to be

\[
U_t = \text{esssup}_{\tau \in \mathcal{T}_t} \mathbb{E}[Z_\tau | \mathcal{F}_{t_k}]
\]

where \(\mathcal{T}_t\) denotes the set of \(\mathcal{F}\)-stopping times with values in \([t,T]\). The integrability properties of \(Z\) ensure that \(U\) is a supermartingale of class (D) and hence has a Doob–Meyer decomposition

\[
U_t = U_0 + M_t^* - A_t^*
\]

where \(M^*\) is a martingale vanishing at zero and \(A^*\) is a predictable integrable increasing process also vanishing at zero. With our assumptions on \(Z\), \(M^*\) is square integrable. Rogers [2002] found an alternative representation of the price at time-0 of the American option as the minimum value of the following optimization problem

\[
U_0 = \inf_{M \in H^2_0} \mathbb{E} \left[ \sup_{t \leq T} (Z_t - M_t) \right] = \mathbb{E} \left[ \sup_{t \leq T} (Z_t - M_t^*) \right] \tag{1}
\]

where \(H^2_0\) denotes the set of square integrable martingales vanishing at zero. A martingale reaching the infimum is called an optimal martingale. As the dual price problem writes
as a convex minimisation problem, the set of all optimal martingales is a convex subset of $H^2_0$. Among the martingales reaching the infimum in $[1]$, some of them actually satisfy the pathwise equality $\sup_{t \leq T} Z_t - M_t = U_0$. These martingales are called surely optimal. Any surely optimal martingale reaches the lower bound in $[1]$ but not all optimal martingales are surely optimal. We refer to [Schoenmakers et al. 2013] for a detailed characterisation of optimal martingales. Anyway, Jamshidian [2007] proved the uniqueness of surely optimal martingales within the continuing region, i.e. for any surely optimal martingale $M$ and any optimal strategy $\tau$, $(M_{t \wedge \tau})_t = (M^*_t)_{t \wedge \tau}$ a.s.

The most famous method using the dual representation $[1]$ is probably the primal–dual approach of Andersen and Broadie [2004], which heavily relies on the knowledge of an optimal exercising policy. The a priori knowledge may take the form of nested Monte Carlo simulations as in Schoenmakers [2005], and Kolodko and Schoenmakers [2004]. To circumvent this difficulty, Rogers [2010] explained how to construct a good martingale. In a Wiener framework, Belomestny et al. [2009] investigated this approach by relying on the martingale representation theorem to build good martingales. When trying to practically use the dual formulation $[1]$, the first difficulty is to find a rich enough but finite dimensional approximation of $H^2_0$ and then we face a finite although potentially high–dimensional minimization problem (see Belomestny [2013] for one way of handling this approach).

The minimization problem $[1]$ can be equivalently formulated as

$$U_0 = \inf_{X \in L^2_{\Omega, F_T, P}} E \left[ \sup_{0 \leq t \leq T} (Z_t - E[X | F_t]) \right]$$

where $L^2_{\Omega, F_T, P}$ is the set of square integrable $F_T$– random variables with zero mean. In this work, we suggest to use the truncated Wiener chaos expansion as a finite dimensional approximation of $H^2_0$ and then we face a finite although potentially high–dimensional minimization problem (see Belomestny [2013] for one way of handling this approach).

The paper starts with the presentation of the Wiener chaos expansion and some of its useful properties in Section 2. Then, we can develop the core of our work in Section 3 in which we explain how the price of the American option can be approximated by the solution of a finite dimensional optimization problem. First, we analyze the properties of the optimization problem in order to prove the convergence of its solution to the American option price. Second, we study its sample average approximation, which makes the problem tractable, and prove its convergence. Based on all these theoretical results, we present our algorithm in Section 4 and discuss its parallel implementation on distributed memory architectures. Finally, some numerical examples are presented in Section 5.

**Notation**

- For $n \geq 1$, $0 = t_0 < t_1 < \cdots < t_n = T$ is a time grid of $[0, T]$ satisfying $\lim_{n \to \infty} \sup_{0 \leq k \leq n-1} |t_{k+1} - t_k| = 0$.
- For $n \geq 1$, the discrete time filtration $\mathcal{G}$ is defined by $\mathcal{G}_k = \sigma(B_{t_{i+1}} - B_{t_i}, i = 0, \ldots, k-1)$ for all $1 \leq k \leq n$, while $\mathcal{G}_0$ is the trivial sigma algebra. Obviously, $\mathcal{G}_k \subset \mathcal{F}_{t_k}$ for all $0 \leq k \leq n$. 
• For $1 \leq r \leq n$, $\mathbb{I}(r) \in \{0,1\}^n$ denotes the vector $(0, \ldots, 0, 1, 0, \ldots, 0)$.  

• For $1 \leq q \leq d$, and $1 \leq r \leq n$, $\mathbb{I}(r,q) \in \mathbb{N}^{n \times d}$ with all components equal to 0 except the component with index $(r,q)$ which is equal to 1.

2 Wiener chaos expansion

For the sake of clearness, we first present the Wiener chaos expansion in the case $d = 1$ (i.e. $B$ is a real valued Brownian motion).

2.1 General framework in dimension one

The iterated stochastic integral approach to the Wiener chaos expansion is not applicable in practice and cannot be generalized to multi-dimensional Brownian motions. Here, we would rather adopt the Hermite polynomials point of view.

Let $H_i$ be the $i$-th Hermite polynomial defined by

$$H_0(x) = 1; \quad H_i(x) = (-1)^i e^{x^2/2} \frac{d^i}{dx^i}(e^{-x^2/2}), \text{ for } i \geq 1.$$  

They satisfy for all integer $i$, $H_i' = H_{i-1}$ with the convention $H_{-1} = 0$. We recall that if $(X,Y)$ is a random normal vector with $\mathbb{E}[X] = \mathbb{E}[Y] = 0$ and $\mathbb{E}[X^2] = \mathbb{E}[Y^2] = 1$

$$\mathbb{E}[H_i(X)H_j(Y)] = i! (\mathbb{E}[XY])^i \mathbb{1}_{i=j}. \quad (3)$$

For all $p \geq 0$, we define the spaces

$$\mathcal{H}_p = \text{span} \left\{ H_p \left( \int_0^T f_t dB_t \right) : f \in L^2([0,T]) \right\} \quad (4)$$

whose $L^2$ closure corresponds to the Wiener chaos of order $p$. We denote the projection of a random variable $F \in L^2(\mathcal{F}_T)$ on to $\bigoplus_{p=0}^p \mathcal{H}_p$ by $C_p(F)$.

We consider the indicator functions of the grid defined by $0 = t_0 < t_1 < \ldots < t_n = T$

$$f_i(t) = \mathbb{1}_{[t_{i-1},t_i)}(t)/\sqrt{t_i - t_{i-1}}, \quad i = 1, \ldots, n,$$

When letting $n$ go to infinity, the family $(f_i)_i$ form an Hilbert basis of $L^2([0,T])$ and moreover

$$\int_0^T f_i(t) dB_t = \frac{B_{t_i} - B_{t_{i-1}}}{\sqrt{t_i - t_{i-1}}} = G_i.$$

Note that the random variables $G_i$ are i.i.d. following the standard normal distribution. We introduce the truncated chaos expansion of order $p$ a random variable $F \in L^2(\mathcal{F}_T)$

$$C_{p,n}(F) = \sum_{\alpha \in A_{p,n}} \lambda_{\alpha} \prod_{i \geq 1} H_{\alpha_i}(G_i) \quad (5)$$

For the sake of clearness, we first present the Wiener chaos expansion in the case $d = 1$ (i.e. $B$ is a real valued Brownian motion).

2.1 General framework in dimension one

The iterated stochastic integral approach to the Wiener chaos expansion is not applicable in practice and cannot be generalized to multi-dimensional Brownian motions. Here, we would rather adopt the Hermite polynomials point of view.

Let $H_i$ be the $i$-th Hermite polynomial defined by

They satisfy for all integer $i$, $H_i' = H_{i-1}$ with the convention $H_{-1} = 0$. We recall that if $(X,Y)$ is a random normal vector with $\mathbb{E}[X] = \mathbb{E}[Y] = 0$ and $\mathbb{E}[X^2] = \mathbb{E}[Y^2] = 1$

$$\mathbb{E}[H_i(X)H_j(Y)] = i! (\mathbb{E}[XY])^i \mathbb{1}_{i=j}. \quad (3)$$

For all $p \geq 0$, we define the spaces

$$\mathcal{H}_p = \text{span} \left\{ H_p \left( \int_0^T f_t dB_t \right) : f \in L^2([0,T]) \right\} \quad (4)$$

whose $L^2$ closure corresponds to the Wiener chaos of order $p$. We denote the projection of a random variable $F \in L^2(\mathcal{F}_T)$ on to $\bigoplus_{p=0}^p \mathcal{H}_p$ by $C_p(F)$.

We consider the indicator functions of the grid defined by $0 = t_0 < t_1 < \ldots < t_n = T$

$$f_i(t) = \mathbb{1}_{[t_{i-1},t_i)}(t)/\sqrt{t_i - t_{i-1}}, \quad i = 1, \ldots, n,$$

When letting $n$ go to infinity, the family $(f_i)_i$ form an Hilbert basis of $L^2([0,T])$ and moreover

$$\int_0^T f_i(t) dB_t = \frac{B_{t_i} - B_{t_{i-1}}}{\sqrt{t_i - t_{i-1}}} = G_i.$$

Note that the random variables $G_i$ are i.i.d. following the standard normal distribution. We introduce the truncated chaos expansion of order $p$ a random variable $F \in L^2(\mathcal{F}_T)$

$$C_{p,n}(F) = \sum_{\alpha \in A_{p,n}} \lambda_{\alpha} \prod_{i \geq 1} H_{\alpha_i}(G_i) \quad (5)$$

For the sake of clearness, we first present the Wiener chaos expansion in the case $d = 1$ (i.e. $B$ is a real valued Brownian motion).

2.1 General framework in dimension one

The iterated stochastic integral approach to the Wiener chaos expansion is not applicable in practice and cannot be generalized to multi-dimensional Brownian motions. Here, we would rather adopt the Hermite polynomials point of view.

Let $H_i$ be the $i$-th Hermite polynomial defined by

$$H_0(x) = 1; \quad H_i(x) = (-1)^i e^{x^2/2} \frac{d^i}{dx^i}(e^{-x^2/2}), \text{ for } i \geq 1.$$  

They satisfy for all integer $i$, $H_i' = H_{i-1}$ with the convention $H_{-1} = 0$. We recall that if $(X,Y)$ is a random normal vector with $\mathbb{E}[X] = \mathbb{E}[Y] = 0$ and $\mathbb{E}[X^2] = \mathbb{E}[Y^2] = 1$

$$\mathbb{E}[H_i(X)H_j(Y)] = i! (\mathbb{E}[XY])^i \mathbb{1}_{i=j}. \quad (3)$$

For all $p \geq 0$, we define the spaces

$$\mathcal{H}_p = \text{span} \left\{ H_p \left( \int_0^T f_t dB_t \right) : f \in L^2([0,T]) \right\} \quad (4)$$

whose $L^2$ closure corresponds to the Wiener chaos of order $p$. We denote the projection of a random variable $F \in L^2(\mathcal{F}_T)$ on to $\bigoplus_{p=0}^p \mathcal{H}_p$ by $C_p(F)$.

We consider the indicator functions of the grid defined by $0 = t_0 < t_1 < \ldots < t_n = T$

$$f_i(t) = \mathbb{1}_{[t_{i-1},t_i)}(t)/\sqrt{t_i - t_{i-1}}, \quad i = 1, \ldots, n,$$

When letting $n$ go to infinity, the family $(f_i)_i$ form an Hilbert basis of $L^2([0,T])$ and moreover

$$\int_0^T f_i(t) dB_t = \frac{B_{t_i} - B_{t_{i-1}}}{\sqrt{t_i - t_{i-1}}} = G_i.$$

Note that the random variables $G_i$ are i.i.d. following the standard normal distribution. We introduce the truncated chaos expansion of order $p$ a random variable $F \in L^2(\mathcal{F}_T)$

$$C_{p,n}(F) = \sum_{\alpha \in A_{p,n}} \lambda_{\alpha} \prod_{i \geq 1} H_{\alpha_i}(G_i) \quad (5)$$
with $A_{p,n} = \{ \alpha \in \mathbb{N}^n \mid \| \alpha \|_1 \leq p \}$ with $\| \alpha \|_1 = \sum_{i \geq 0} \alpha_i$. Using Equation (3), we deduce that the coefficients of the above decomposition are uniquely determined by

$$\lambda_\alpha = \frac{\mathbb{E} \left[ F \prod_{i \geq 1} H_{\alpha_i}(G_i) \right]}{(\prod_{i \geq 1} \alpha_i!)}. \quad (6)$$

This formula can be rewritten more clearly by introducing the generalized Hermite polynomials defined for any multi–index $\alpha = (\alpha_i)_{i \geq 1} \in \mathbb{N}^N$

$$\hat{H}_\alpha(x) = \prod_{i \geq 1} H_{\alpha_i}(x_i), \quad \text{for } x \in \mathbb{R}^N.$$ 

With this notation, Equation (5) becomes

$$C_{p,n}(F) = \sum_{\alpha \in A_{p,n}} \lambda_\alpha \hat{H}_\alpha(G_1, \ldots, G_n).$$

**Proposition 2.1.** Let $F$ be a real valued random variable in $L^2(\Omega, \mathcal{F}_T, \mathbb{P})$ and let $k \in \{1, \ldots, n\}$ and $p \geq 0$

$$\mathbb{E}[C_{p,n}(F)|\mathcal{F}_{t_k}] = \sum_{\alpha \in A_{p,n}^k} \lambda_\alpha \hat{H}_\alpha(G_1, \ldots, G_n)$$

with $A_{p,n}^k = \{ \alpha \in \mathbb{N}^n \mid \| \alpha \|_1 \leq p, \alpha_\ell = 0 \ \forall \ell > k \}$.

**Proof.** Taking the conditional expectation in Eq. (5) leads to

$$\mathbb{E}[C_{p,n}(F)|\mathcal{F}_{t_k}] = \sum_{\alpha \in A_{p,n}^k} \lambda_\alpha \prod_{i = 1}^k H_{\alpha_i}(G_i) \mathbb{E} \left[ \prod_{i = k+1}^n H_{\alpha_i}(G_i) | \mathcal{F}_{t_k} \right]. \quad (7)$$

Since the Brownian increments after time $t_k$ are independent of $\mathcal{F}_{t_k}$ and are independent of one another , $\mathbb{E} \left[ \prod_{i = k+1}^n H_{\alpha_i}(G_i) | \mathcal{F}_{t_k} \right] = \prod_{i = k+1}^n \mathbb{E} [H_{\alpha_i}(G_i)]$, which is zero as soon as $\sum_{i = k+1}^n \alpha_i > 0$. Hence, the sum in Equation (7) is reduced to the sum over the set of multi–indices $\alpha \in A_{p,n}$ such that $\alpha_i = 0$ for all $i > k$, which is exactly the definition of the set $A_{p,n}^k$. 

**Remark 2.2.** Since the sum appearing in $\mathbb{E}[C_{p,n}(F)|\mathcal{F}_{t_k}]$ is reduced to a sum over the set of multi–indices $\alpha \in A_{p,n}^k$, it actually only depends on the first $k$ increments $(G_1, \ldots, G_k)$. One can easily check that $\mathbb{E}[C_{p,n}(F)|\mathcal{F}_{t_k}]$ is actually given by the chaos expansion of $F$ on the first $k$ Brownian increments. Hence, computing a conditional expectation simply boils down to dropping term. While it may look like a naive way to proceed, it is indeed correct in our setting.

**Proposition 2.3.** Let $F$ be a real valued random variable in $L^2(\Omega, \mathcal{F}_T, \mathbb{P})$ and let $k \in \{1, \ldots, n\}$ and $p \geq 1$. For all $t \in [t_{r-1}, t_r]$ with $1 \leq r \leq k$,

$$D_t \mathbb{E}[C_{p,n}(F)|\mathcal{F}_{t_k}] = \frac{1}{\sqrt{h}} \sum_{\alpha \in A_{p,n}^k, \alpha_r \geq 1} \lambda_\alpha \hat{H}_{\alpha - \mathbb{I}(r)}(G_1, \ldots, G_n)$$

where $\alpha - \mathbb{I}(r) = (\alpha_1, \ldots, \alpha_{r-1}, \alpha_r - 1, \alpha_{r+1}, \ldots, \alpha_n)$.  

5
Proof. From Proposition 2.1, we know that for all $1 \leq k \leq n$

$$E[C_{p,n}(F) \mid \mathcal{F}_{t_k}] = \sum_{\alpha \in A_{p,n}^k} \lambda_{\alpha} \tilde{H}_{\alpha}(G_1, \ldots, G_n)$$

Let $r \leq k$ and $t \in [t_{r-1}, t_r]$. The chain rule for the Malliavin derivative yields

$$D_t E[C_{p,n}(F) \mid \mathcal{F}_{t_k}] = \sum_{\alpha \in A_{p,n}^k} \lambda_{\alpha} D_t \left( \prod_{i=1}^{k} H_{\alpha_i}(G_i) \right)$$

$$= \prod_{i=1, i \neq r}^{k} H_{\alpha_i}(G_i) H'_{\alpha_r}(G_r)$$

$$= 1_{\alpha_r \geq 1} \prod_{i=1, i \neq r}^{k} H_{\alpha_i}(G_i) H_{\alpha_r-1}(G_r)$$

$$= 1_{\alpha_r \geq 1} \tilde{H}_{\alpha_r-2(r)}(G_1, \ldots, G_n).$$

\[\square\]

**2.2 Multi–dimensional chaos expansion**

In the previous section, we explained how a random variable measurable for a sigma field generated by a one–dimensional Brownian motion could be approximated by a finite sum of Hermite polynomials of Brownian increments.

In this section, we are back to our original multi–dimensional setting, as explained in Section 1. The process $B$ is a Brownian motion with values in $\mathbb{R}^d$. The key idea to extend the Hermite polynomial expansion to a higher dimensional setting is to consider a tensor product of Hermite polynomials evaluated on a tensor basis of $L^2(\mathbb{R}^d)$.

Consider the functions $(h_i)_j$ with values in $\mathbb{R}^d$ defined by

$$h^j_i(t) = \frac{1_{[t_{i-1}, t_i]}(t)}{\sqrt{h}} e_j, \quad i = 1, \ldots, n, \quad j = 1, \ldots, d$$

where $(e_1, \ldots, e_d)$ denotes the canonical basis of $\mathbb{R}^d$. The $p$–th order Wiener chaos $C_{p,n}$ is defined as the closure of

$$\left\{ \prod_{j=1}^{d} \tilde{H}_{\alpha_j}(G^j_1, \ldots, G^j_n) : \alpha \in (\mathbb{N}^n)^d, \|\alpha\|_1 \leq p \right\}$$

where $\|\alpha\|_1 = \sum_{i=1}^{n} \sum_{j=1}^{d} \alpha^j_i$ and $G^j_i = \frac{B^j_i - B^j_{i-1}}{\sqrt{h}}$. Using the independence of the Brownian increments and the orthogonality of the Hermite polynomials, the chaos expansion of a square integrable random variable $F$ is given by

$$C_{p,n}(F) = \sum_{\alpha \in A_{p,n}^{\otimes d}} \lambda_{\alpha} \tilde{H}_{\alpha}^{\otimes d}(G_1, \ldots, G_n)$$

where

$$\tilde{H}_{\alpha}^{\otimes d}(G_1, \ldots, G_n) = \prod_{j=1}^{d} \tilde{H}_{\alpha^j}(G^j_1, \ldots, G^j_n) \quad \forall \alpha \in (\mathbb{N}^n)^d$$

$$A_{p,n}^{\otimes d} = \left\{ \alpha \in (\mathbb{N}^n)^d : \|\alpha\|_1 \leq p \right\}.$$  \(\text{(8)}\)
With an obvious abuse of notation, we write, for \( \lambda \in \mathbb{R}^{A_{p,n}^{\otimes d}} \),
\[
C_{p,n}(\lambda) = \sum_{\alpha \in A_{p,n}^{\otimes d}} \lambda_{\alpha} \Phi_{\alpha}^{\otimes d}(G_1, \ldots, G_n).
\]

We also introduce the set of multi-indices truncated after time \( t_k \)
\[
A_{p,n}^{\otimes d,k} = \left\{ \alpha \in A_{p,n}^{\otimes d} : \forall j \in \{1, \ldots, d\}, \forall \ell > k, \alpha_j^{\ell} = 0 \right\}.
\] (9)

We introduce the set \( C_{p,n} \) defined by
\[
C_{p,n} = \left\{ F \in L^2(\Omega, F_T, P) : F = C_{p,n}(F) \text{ a.s.} \right\}.
\]

We can easily deduce the multidimensional counterpart of Proposition 2.1

**Proposition 2.4.** Let \( F \) be a real valued random variable in \( L^2(\Omega, F_T, P) \) and let \( k \in \{1, \ldots, n\} \) and \( p \geq 0 \)
\[
\mathbb{E}[C_{p,n}(F)|F_t_k] = \sum_{\alpha \in A_{p,n}^{\otimes d,k}} \lambda_{\alpha} \Phi_{\alpha}^{\otimes d}(G_1, \ldots, G_n).
\]

**Remark 2.5.** The discrete time sequence \( (\mathbb{E}[C_{p,n}(F)|F_t_k])_{0 \leq k \leq n} \) is of course adapted to the filtration \( (F_t_k)_k \) but also to the smaller filtration \( (G_k)_k \). This property plays a crucial when approximating a random variable \( F \in L^2(\Omega, G_n, P) \) as we know from [Nualart, 1998, Theorem 1.1.1] that in such a case \( \lim_{p \to \infty} C_{p,n}(F) = F \) in the \( L^2 \)-sense. This result holds for the fixed value \( n \). If \( F \) were only \( F_T \)-measurable and not \( G_n \)-measurable, we would need to let both \( p \) and \( n \) go to infinity, \( \lim_{p \to \infty, n \to \infty} C_{p,n}(F) = F \).

**Proposition 2.6.** Let \( F \) be a real valued random variable in \( L^2(\Omega, F_T, P) \) and let \( k \in \{1, \ldots, n\} \) and \( p \geq 1 \).
For all \( t \in [t_{r-1}, t_r] \) with \( 1 \leq r \leq k \), and \( q = 1, \ldots, d \),
\[
D_q^t \mathbb{E}[C_{p,n}(F)|F_t_k] = \frac{1}{\sqrt{h}} \sum_{\alpha \in A_{p,n}^{\otimes d,k}} \lambda_{\alpha} \Phi_{\alpha-\mathbb{1}(r,q)}^{\otimes d}(G_1, \ldots, G_n)
\]
where \( (\alpha - \mathbb{1}(r,q))_i^j = \alpha_i^j - 1_{j=q, i=r} \).

In this multi-dimensional setting, the Malliavin derivative operator is actually a gradient operator \( D_t = (D_1^t, \ldots, D_d^t) \).

**Proof.** From Proposition 2.4 we know that for all \( 1 \leq k \leq n \)
\[
\mathbb{E}[C_{p,n}(F)|F_t_k] = \sum_{\alpha \in A_{p,n}^{\otimes d,k}} \lambda_{\alpha} \prod_{j=1}^d \Phi_{\alpha}^{\otimes j}(G_1^j, \ldots, G_n^j).
\]
Let $r \leq k$ and $t \in \left[t_{r-1}, t_r\right]$. Let $1 \leq q \leq d$. The chain rule for the Malliavin derivative yields

\[
D_t^q \mathbb{E}[C_{p,n}(F)|\mathcal{F}_{t_k}]
= \sum_{\alpha \in A_{p,n}^{\otimes d,k}} \lambda_\alpha \left( \prod_{j=1}^d \hat{H}_{\alpha_j}(G_1^j, \ldots, G_n^j) \right)
= \sum_{\alpha \in A_{p,n}^{\otimes d,k}} \lambda_\alpha \left( \prod_{j=1, j \neq q}^d \hat{H}_{\alpha_j}(G_1^j, \ldots, G_n^j) \right) D_t^q \left( \hat{H}_{\alpha_q}(G_1^q, \ldots, G_n^q) \right)
= \frac{1}{\sqrt{h}} \sum_{\alpha \in A_{p,n}^{\otimes d,k}} \lambda_\alpha \left( \prod_{j=1, j \neq q}^d \hat{H}_{\alpha_j}(G_1^j, \ldots, G_n^j) \right) \hat{H}_{\alpha_{q\!-\!1}(r)}(G_1^q, \ldots, G_n^q)
= \frac{1}{\sqrt{h}} \sum_{\alpha \in A_{p,n}^{\otimes d,k}, \alpha_q \geq 1} \lambda_\alpha \hat{H}_{\alpha_{q\!-\!1}(r)}(G_1, \ldots, G_n).
\]

\[\blacksquare\]

**Remark 2.7.** The conditional expectation preserves the nature of a chaos expansion. Similarly, the Malliavin derivative of a chaos expansion still writes as a chaos expansion and hence is a Hermite polynomial of Brownian increments. The roots of a non zero polynomial being a zero measure set and since the Brownian increments have a joined density, the Malliavin derivative of a chaos expansion is almost surely non zero as soon as one of the coefficients $\lambda_\alpha$ is non zero for $\alpha \in A_{p,n}^{\otimes d,k}$ such that $\alpha_q \geq 1$ for some $j \in \{1, \ldots, d\}$.

For $i, k \in \{1, \ldots, n\}$, with $i < k$, we introduce the set $A_{p,n}^{\otimes d,i;k}$ defined as $A_{p,n}^{\otimes d,k} \setminus A_{p,n}^{\otimes d,i}$.

\[
A_{p,n}^{\otimes d,i;k} = \{ \alpha \in (\mathbb{N}^p)^d : \|\alpha\|_1 \leq p, \text{ and } \forall 1 \leq j \leq d, \forall \ell \notin \{i+1, \ldots, k\}, \alpha_\ell = 0 \}. \tag{10}
\]

### 3 Pricing American options using Wiener chaos expansion and sample average approximation

In this section, we aim at approximating the dual price (2) by a tractable optimization problem. This involves two kinds of approximations: first, approximate the space $L_0^2(\Omega, \mathcal{F}_T, \mathbb{P})$ by a finite dimensional vector space; second, replace the expectation by a sample average approximation.

The dual price writes

\[
\inf_{X \in L_0^2(\Omega, \mathcal{F}_T, \mathbb{P})} \mathbb{E} \left[ \sup_{0 \leq t \leq T} \left( Z_t - \mathbb{E}[X|\mathcal{F}_t] \right) \right].
\]

In this optimization problem, we replace $X$ by its chaos expansion $C_{p,n}(X)$, which has no constant term as $\mathbb{E}[X] = 0$ and we approximate the supremum by a discrete time maximum. Then, we face a finite dimensional minimization problem to determine the optimal solution with the subset $C_{p,n}$

\[
\inf_{\lambda \in \mathbb{R}^{A_{p,n}^{\otimes d}}, \lambda_0 = 0} \mathbb{E} \left[ \max_{0 \leq k \leq n} \left( Z_{t_k} - \mathbb{E}[C_{p,n}(\lambda)|\mathcal{F}_{t_k}] \right) \right]. \tag{11}
\]

In Section 3.1, we prove that this optimization problem is convex and has a solution (see Proposition 3.2) and converges to the price of the American option (see Proposition 3.3).
Moreover, as the cost function is differentiable, any minimizer is a zero of the gradient (see Proposition 3.6), which makes it easier to derive an algorithm.

To come up with a fully implementable algorithm, Section 3.2 presents the sample average approximation of (11), which consists in replacing the expectation by a Monte Carlo summation. We prove in Proposition 3.7 that the solution of the sample average approximation converges to the solution of (11) when the number of samples goes to infinity.

Remark 3.1. Belomestny [2013] considered a penalized version of (1) of the form

$$\inf_{M \in H_0^1} \left( \mathbb{E} \left[ \sup_{0 \leq t \leq T} (Z_t - M_t) \right] + \kappa \text{Var} \left( \sup_{0 \leq t \leq T} (Z_t - M_t) \right) \right)$$

with $\kappa > 0$. This criteria naturally selects almost sure optimal martingales (see Schoenmakers et al. [2013]) among those solving (1). Although adding such a penalization looks interesting from a theoretical point of view, it breaks the convexity of the minimization criterion, which makes it less appealing from a practical of view. Moreover, the convergence of our sample average approximation developed in Section 3.2 requires convexity.

3.1 A stochastic optimization approach

We fix $p \geq 1$ and define the random functions $v_{p,n}(\cdot, \cdot; Z, G) : \mathbb{R}^{A_{p,n}} \times \{0, \ldots, n\}$ by

$$v_{p,n}(\lambda, k; Z, G) = Z_{t_k} - \sum_{\alpha \in A_{p,n}^{\otimes d}} \lambda_\alpha \mathbb{E} \left[ \bar{H}_{\alpha}^{\otimes d}(G_1, \ldots, G_n) \left| F_{t_k} \right. \right],$$

With the help of Proposition 2.1, the random functions $v_{p,n}$ can be rewritten

$$v_{p,n}(\lambda, k; Z, G) = Z_{t_k} - \sum_{\alpha \in A_{p,n}^{\otimes d}} \lambda_\alpha \bar{H}_{\alpha}^{\otimes d}(G_1, \ldots, G_n).$$

We consider the cost function $V_{p,n} : \mathbb{R}^{A_{p,n}^{\otimes d}} \rightarrow \mathbb{R}$ defined by

$$V_{p,n}(\lambda) = \mathbb{E} \left[ \max_{0 \leq k \leq n} v_{p,n}(\lambda, k; Z, G) \right]$$

(12)

and we approximate the solution of (2) by

$$\inf_{\lambda \in \mathbb{R}^{A_{p,n}^{\otimes d}}, \lambda_0 = 0} V_{p,n}(\lambda).$$

(13)

3.1.1 Convergence results

Proposition 3.2. The minimization problem (13) has at least one solution.

Proof. As the supremum of linear functions is convex, the random function $\lambda \mapsto \max_{k \leq n} v_{p,n}(\lambda, t_k; Z, G)$ is almost surely convex. The convexity of $V_{p,n}$ ensues from the linearity of the expectation.

Let us prove that $V_{p,n}(\lambda) \rightarrow \infty$ when $|\lambda| \rightarrow \infty$. Note that $V_{p,n}(\lambda) \geq \mathbb{E} [C_{p,n}(\lambda) -] \geq \frac{1}{2} \mathbb{E} [|C_{p,n}(\lambda)|]$, where we have used that $|x| = 2x_+ + x$ and $\mathbb{E}[C_{p,n}(\lambda)] = 0$.

$$\mathbb{E} [|C_{p,n}(\lambda)|] = |\lambda| \mathbb{E} [|C_{p,n}(\lambda/|\lambda|)|] \geq |\lambda| \inf_{\mu \in \mathbb{R}^{A_{p,n}^{\otimes d}}, |\mu|=1} \mathbb{E} [|C_{p,n}(\mu)|].$$
By a standard continuity argument, the infimum is attained. Moreover, it is strictly positive as otherwise there would exist $\mu \in \mathbb{R}^{A_0}_{\otimes d}$ with $|\mu| = 1$ s.t. $E[|C_{p,n}(\mu)|] = 0$. Using the orthogonality of the family $\left( H^{\otimes d}_{\alpha} \right)_{\alpha \in A_0^{\otimes n}}$, we would immediately deduce that $\mu = 0$. Hence, we show that $V_{p,n}(\lambda) \to \infty$ when $|\lambda| \to \infty$. The growth at infinity of $V_{p,n}$ combined with its convexity yields the existence of a solution to the minimization problem (13).

Proposition 3.2 ensures the existence of $\lambda^\sharp_{p,n}$ solving (13), i.e.

$$V_{p,n}(\lambda^\sharp_{p,n}) = \inf_{\lambda \ s.t. \ \lambda_0 = 0} V_{p,n}(\lambda).$$

Moreover, $\nabla V_{p,n}(\lambda^\sharp_{p,n}) = 0$. This characterization of an optimal solution will be of prime importance to practically devise an algorithm.

**Proposition 3.3.** The solution of the minimization problem (13), $V_{p,n}(\lambda^\sharp_{p,n})$, converges to $U_0$ when both $p$ and $n$ go to infinity.

**Proof.** We introduce the truncated chaos expansion of $M^\sharp_{\lambda}$ and denote its coefficients by $\lambda^\star_{p,n}$, i.e. $C_{p,n}(M^\sharp_{\lambda}) = C_{p,n}(\lambda^\star_{p,n})$. Clearly, $U_0 \leq V_{p,n}(\lambda^\sharp_{p,n}) \leq V_{p,n}(\lambda^\star_{p,n})$. Then, we obtain the following result

$$0 \leq V_{p,n}(\lambda^\sharp_{p,n}) - U_0 \leq V_{p,n}(\lambda^\star_{p,n}) - U_0$$

$$\leq \mathbb{E} \left[ \max_k (Z_{t_k} - \mathbb{E}[C_{p,n}(\lambda^\star_{p,n}) | \mathcal{F}_{t_k}]) - \max_k (Z_{t_k} - M^\star_{t_k}) \right]$$

$$\leq \mathbb{E} \left[ \max_k \left| M^\star_{t_k} - \mathbb{E}[C_{p,n}(\lambda^\star_{p,n}) | \mathcal{F}_{t_k}] \right| \right]$$

$$\leq \mathbb{E} \left[ \max_k \mathbb{E} \left[ \left| M^\star_{t_k} - C_{p,n}(\lambda^\star_{p,n}) \right| \mathcal{F}_{t_k} \right]^2 \right]$$

$$\leq 2 \left\| M^\star_{\lambda} - C_{p,n}(M^\star_{\lambda}) \right\|^2$$

(14)

where the last upper–bound ensues from Doob’s inequality. Note that this bound does not depend on $\lambda^\star_{p,n}$.

Nualart [1998] Theorem 1.1.1, Proposition 1.1.1] yields the convergence result when $p$ and $n$ go to infinity. □

**Corollary 3.4.** Consider the Bermudan option with exercising dates $t_0, \ldots, t_n$ and with discounted payoff $(Z_{t_k})_k$ assumed to be $\mathcal{G}$–adapted. Then, $V_{p,n}(\lambda^\sharp_{p,n})$ converges to the price of the Bermudan option when $p$ goes to infinity.

**Proof.** Let $\hat{U}_k$ be the price at time–$t_k$ of the Bermudan option. The sequence $(\hat{U}_k)_{0 \leq k \leq n}$ is a supermartingale admitting the Doob–Meyer decomposition $\hat{U}_k = \hat{U}_0 + \hat{M}_k - \hat{A}_k$ where $\hat{M}$ is a square integrable $(\mathcal{G}_k)_{k}$–martingale and $\hat{A}$ a predictable increasing process for the filtration $\mathcal{G}$. The price at time–$0$ of the Bermudan option also writes

$$\hat{U}_0 = \inf_{X \in L^2_{\mathbb{P}}(\Omega, \mathcal{G}_0, \mathbb{P})} \mathbb{E} \left[ \max_{0 \leq k \leq n} (Z_{t_k} - \mathbb{E}[X | \mathcal{G}_k]) \right].$$

Clearly, $C_{p,n}(\lambda) \in L^2(\Omega, \mathcal{G}_n, \mathbb{P})$ for any $\lambda$ such that $\lambda_0 = 0$ and moreover $V_{p,n}(\lambda^\sharp_{p,n}) \geq \hat{U}_0$. Then, by reproducing the steps in (14), we get

$$0 \leq V_{p,n}(\lambda^\star_{p,n}) - \hat{U}_0 \leq 2 \left\| \hat{M}_n - C_{p,n}(\hat{M}_n) \right\|^2.$$

We deduce from Remark 2.5 that this upper–bound goes to zero as $p$ tends to infinity. □
From [13], we know that
\[
|V_{p,n}(\lambda_{p,n}^k) - U_0| \leq 2 \|M_p^* - C_p(M_p^*)\|_2 + 2 \|C_p(M_T^*) - C_{p,n}(M_T^*)\|_2,
\]
which enables us to separate the effect of the order of the chaos approximation from the impact of the truncation of the basis of \(L^2([0,T])\). We apply [Geiss and Labart 2016, Lemma 2.4] to handle the error w.r.t \(p\) and [Briand and Labart 2014, Lemma 4.14] the one due to \(n\). Then, we obtain the following convergence rate.

**Proposition 3.5.** Assume \(M_p^* \in \mathcal{D}_{m,2}^m\) for some \(1 \leq m \leq p + 1\), and for all \(\ell \leq p\) and all \((t_1, \ldots, t_\ell) \in [0,T]^\ell\) and \((s_1, \ldots, s_\ell) \in [0,T]^\ell\)
\[
|\mathbb{E}[D_{t_1,\ldots,t_\ell}M_p^*] - \mathbb{E}[D_{s_1,\ldots,s_\ell}M_p^*]| \leq K_{\ell}(|t_1 - s_1|^{\beta^*} + \cdots + |t_\ell - s_\ell|^{\beta^*})
\]
where \((K_\ell)_{\ell}\) is an increasing sequence of positive real numbers and \(\beta^*\) is a positive real constant. Then,
\[
0 \leq V_{p,n}(\lambda_{p,n}^j) - U_0 \leq 2 \|D^mM_p^*\|_{L^2(\Omega \times [0,T]^m)} + 2\sqrt{T(1 + T)}e^\frac{T}{\sqrt{n}} K_p.
\]

### 3.1.2 Regularity of the optimization problem

Most convex optimization algorithms mainly rely on the gradient of the cost function. We end this section by proving that \(V_{p,n}\) is almost everywhere differentiable, which implies that \(\nabla V_{p,n}(\lambda_{p,n}^j) = 0\). We introduce the set of random indices for which the pathwise maximum is attained
\[
\mathcal{I}(\lambda, Z, G) = \left\{ 0 \leq k \leq n : v_{p,n}(\lambda, k; Z, G) = \max_{\ell \leq n} v_{p,n}(\lambda, \ell; Z, G) \right\}.
\]

**Proposition 3.6.** Let \(p \geq 1\). Assume that
\[
\forall 1 \leq r \leq k \leq n, \forall F \in \mathcal{F}_{t_{r-1}}, \text{ measurable, } F \in \mathcal{C}_{p-1,n}, \, F \neq 0, \, \exists q' \in \{1, \ldots, d\} \text{ s.t. } P\left(\forall t \in [t_{r-1}, t_r], D_{t_k}^q Z_{t_k} + F = 0 \mid Z_{t_k} > 0\right) = 0. \quad (15)
\]

Define the set
\[
\Lambda = \{ (\lambda_\alpha)_{\alpha \in A_{p,n}^{q,d}} \in \mathbb{R}^{A_{p,n}^{q,d}} : \forall r \in \{1, \ldots, n\}, \exists \alpha \text{ s.t. } \alpha_r^q \geq 1 \text{ for some } q \in \{1, \ldots, d\} \text{ and } \lambda_\alpha \neq 0\}.
\]

Then, the function \(V_{p,n}\) is differentiable on the set \(\Lambda\) and the gradient \(\nabla V_{p,n}\) is given by
\[
\nabla V_{p,n}(\lambda) = \mathbb{E}\left[ \mathbb{E}\left[ \hat{H}^{q,d}(G_1, \ldots, G_n) \mid \mathcal{F}_{t_i}\right]_{i(t)=Z(\lambda,Z,G)} \right].
\]

We refer the reader to section 5.1 for a detailed discussion on which kinds of models and payoffs satisfy (15).

**Proof.** We already know that the function \(V_{p,n}\) is convex. Moreover, for all \(Z\) and \(G\), the function \(\lambda \mapsto \max_{k \leq n} v_{p,n}(\lambda, k, Z, G)\) has a subdifferential given by
\[
\left\{ \sum_{i \in \mathcal{I}(\lambda, Z, G)} \beta_i \mathbb{E}[\hat{H}^{q,d}(G_1, \ldots, G_n)\mid \mathcal{F}_{t_i}] : \beta_i \geq 0, \beta_i \mathcal{F}_T - \text{measurable s.t. } \sum_{i \in \mathcal{I}(\lambda, Z, G)} \beta_i = 1 \right\}
\]
Then, the expression of the subdifferential $\partial V_{p,n}(\lambda)$ ensues from [Bertsekas, 1973].

$$\partial V_{p,n}(\lambda) = \left\{ E \left[ \sum_{i \in \mathcal{I}(\lambda, Z, G)} \beta_i [\tilde{H} \circ \bar{d}(G_1, \ldots, G_n)|F_t] \right] : \beta_i \geq 0, \beta_i \mathcal{F}_T - \text{meas.}, \sum_i \beta_i = 1 \right\}.$$

It is sufficient to prove for any $\lambda \in \Lambda$, the set $\mathcal{I}(\lambda, Z, G)$ is almost surely reduced to a single value as in this case the subdifferential $\partial V_{p,n}(\lambda)$ contains a unique element, which is then the gradient.

By the equality

$$\{ \exists t \neq t_k : v_{p,n}(\lambda, i; Z, G) = v_{p,n}(\lambda, k; Z, G) \} = \bigcup_{i < k \leq n} \{ v_{p,n}(\lambda, i; Z, G) = v_{p,n}(\lambda, k; Z, G) \},$$

it is sufficient to prove that for any $i < k \leq n$, $\mathbb{P}(v_{p,n}(\lambda, i; Z, G) = v_{p,n}(\lambda, k; Z, G)) = 0$. Fix $i < k$ and set $X_\lambda = v_{p,n}(\lambda, k; Z, G) - v_{p,n}(\lambda, i; Z, G)$. According to [Nualart, 1998, Theorem 2.1.3], proving that $\|DX_\lambda\|_{L^2([0,T])} > 0$ a.s ensures that $X_\lambda$ is absolutely continuous with respect to the Lebesgue measure on $\mathbb{R}$ and hence is almost surely non zero. Note that $\|DX_\lambda\|_{L^2([0,T])}^2 = \int_T |D_tX_\lambda|^2 dt \geq \int_{t_k} |D_tX_\lambda|^2 dt$.

For $t \in [0, T]$, and $1 \leq q \leq d$, the Malliavin derivative of $X_\lambda$ is given by

$$D^q_tX_\lambda = D^q_t(Z_{t_k} - Z_t) - D^q_t \left( \sum_{\alpha \in A_{p,n}^{d,i}} \lambda_\alpha \tilde{H}^{-d}(G_1, \ldots, G_n) - \sum_{\alpha \in A_{p,n}^{d,i}} \lambda_\alpha \tilde{H}^{-d}(G_1, \ldots, G_n) \right).$$

Clearly, w.p.1. $D^q_tX_\lambda = 0$ for all $t > t_k$. Hence,

$$\{ D^q_tX_\lambda = 0 \ \forall \ t \in [0, T] \ \text{a.e.} \} \subset \bigcap_{i < r \leq k} \{ D^q_tX_\lambda = 0 \ \forall \ t \in [t_{r-1}, t_r] \ \text{a.e.} \}.$$

From Proposition 2.3 we can deduce that for $i < r \leq k$, and $t \in [t_{r-1}, t_r]$

$$D^q_tX_\lambda = D^q_t(Z_{t_k}) + \frac{1}{\sqrt{h}} \sum_{\alpha \in A_{p,n}^{d,i}, \alpha_i \geq 1} \lambda_\alpha \tilde{H}^{-d}_{\alpha - 1}(r,q) (G_1, \ldots, G_n).$$

Using the locality of the operator $D$, we know that a.s $D^q_t(Z_{t_k}) = 0$ for all $t \in [t_{r-1}, t_r]$ on the set $\{ Z_{t_k} = 0 \}$. Hence, we can write for any pair $(q, q') \in \{1, \ldots, d\}^2$

$$\mathbb{P}(\forall t \in [t_{r-1}, t_r], D_tX_\lambda = 0) \leq \mathbb{P} \left( \frac{1}{\sqrt{h}} \sum_{\alpha \in A_{p,n}^{d,i}, \alpha_i \geq 1} \lambda_\alpha \tilde{H}^{-d}_{\alpha - 1}(r,q) (G_1, \ldots, G_n) = 0, Z_{t_k} = 0 \right) + \mathbb{P} \left( \forall t \in [t_{r-1}, t_r], D^q_tX_\lambda = 0 \mid Z_{t_k} > 0 \right) \mathbb{P}(Z_{t_k} > 0). \quad (16)$$

Assume $\lambda \in \Lambda$ and pick the corresponding value of $q$, then the chaos polynomial $\frac{1}{\sqrt{h}} \sum_{\alpha \in A_{p,n}^{d,i}, \alpha_i \geq 1} \lambda_\alpha \tilde{H}^{-d}_{\alpha - 1}(r,q) (G_1, \ldots, G_n)$ is either a non zero constant if $p = 1$ or it has an
absolutely continuous density thanks to Remark 2.7. In both cases, it is a non zero element of $C_{p−1,n}$ and

$$
\mathbb{P}\left( \frac{1}{\sqrt{h}} \sum_{\alpha \in \mathcal{A}^{p,n}_d, \alpha^2 \geq 1} \lambda_{\alpha} \tilde{H}_{\alpha - 1}(r, 0) (G_1, \ldots, G_n) = 0 \right) = 0.
$$

To treat the other term, we pick a $q' \in \{1, \ldots, d\}$ as in (15) and it yields that

$$
\mathbb{P}\left( \forall t \in [t_{r-1}, t_r], D_{t}^{q'} X_\lambda = 0 \mid Z_{t_k} > 0 \right) = 0.
$$

Hence, we deduce from the last two results and (16) that

$$
\|D X_\lambda\|_2^2 > 0 \text{ a.s.}
$$

which ends the proof.

\section{3.2 The Sample Average Approximation point of view}

From (14), we can approximate $U_0$ by solving the minimization problem (13), which admits at least one solution $\lambda^\sharp_{p,n}$, ie.

$$
V_{p,n}(\lambda^\sharp_{p,n}) = \inf_{\lambda \in A^{p,n}_d, \lambda_0 = 0} V_{p,n}(\lambda)
$$

where $V_{p,n}$ defined by (12) is an expectation, which is barely tractable. To practically solve such a problem, two differently approaches are commonly used. Either, one uses a stochastic algorithm or one replaces the expectation by a sample average approximation. In this work, we target large problems, which puts scalability as a primary requirement. The intrinsic sequential nature of stochastic algorithms has led us to prefer the sample average approximation approach. Moreover, we are more interested in the value function at the minimum rather than in its minimizer and unlike stochastic algorithm, standard optimization algorithms provide both at once.

We introduce the sample average approximation of $V_{p,n}$ defined by

$$
V_{p,n}^m(\lambda) = \frac{1}{m} \sum_{i=1}^{m} \max_{0 \leq k \leq n} v_{p,n}(\lambda; Z_{i}^{(i)}, G_{i}^{(i)})
$$

where $(Z_{i}^{(i)}, G_{i}^{(i)})_{1 \leq i \leq m}$ are i.i.d samples from the distribution of $(Z, G)$.

For large enough $m$, $V_{p,n}^m$ inherits from the smoothness of $V_{p,n}$ and is in particular convex and a.s. differentiable at any point with no zero component. Then, we easily deduce from Proposition 3.2 that there exits $\lambda_{p,n}^m$ such that

$$
V_{p,n}^m(\lambda_{p,n}^m) = \inf_{\lambda \in R^{A^{p,n}_d}}, \lambda_0 = 0 V_{p,n}^m(\lambda)
$$

and moreover $\nabla V_{p,n}^m(\lambda_{p,n}^m) = 0$. The main difficulty in studying the convergence of $V_{p,n}^m(\lambda_{p,n}^m)$ when $m$ goes to infinity comes from the non compactness of the set $R^{A^{p,n}_d}$. To circumvent this problem, we adapt to non strictly convex problems the technique used in Jourdain and Lelong [2009].
Proposition 3.7. The sequence $V_{p,n}(\lambda_{p,n}^m)$ converges a.s. to $V_{p,n}(\lambda_{p,n}^\gamma)$ when $m \to \infty$. Moreover, the distance between $\lambda_{p,n}^m$ and the convex set of minimizers in (13) converges to zero as $m$ goes to infinity.

Proof. The random function $\lambda \in \mathbb{R}^{p,d} \mapsto \max_{0 \leq k \leq n} v_{p,n}(\lambda; Z, G)$ is a.s. continuous. For $\Lambda > 0$,

$$
sup_{|\lambda| \leq \Lambda} \max_{0 \leq k \leq n} v_{p,n}(\lambda; Z, G) \leq \max_{0 \leq k \leq n} Z_{tk} + \sup_{|\lambda| \leq \Lambda} \max_{0 \leq k \leq n} \sum_{\alpha \in A_{p,n}^d} \lambda_\alpha \mathbb{E} \left[ \hat{H}_\alpha^d (G_1, \ldots, G_n) \left| \mathcal{F}_{tk} \right. \right]
$$

$$
\leq \max_{0 \leq k \leq n} Z_{tk} + \sum_{\alpha \in A_{p,n}^d} \lambda_\alpha \mathbb{E} \left[ \hat{H}_\alpha^d (G_1, \ldots, G_n) \left| \mathcal{F}_{tk} \right. \right]
$$

$$
\leq \max_{0 \leq k \leq n} Z_{tk} + \Lambda \sum_{\alpha \in A_{p,n}^d} \max_{0 \leq k \leq n} \mathbb{E} \left[ \hat{H}_\alpha^d (G_1, \ldots, G_n) \left| \mathcal{F}_{tk} \right. \right]
$$

The right hand side of the above inequality is integrable. We apply [Rubinstein and Shapiro, 1993 Lemma A1 Chapter 2] to deduce that a.s. $V_{p,n}^m$ converges locally uniformly to $V_{p,n}$.

From the proof of the Proposition 3.2, there exits $\Lambda > 0$ such that

$$
\gamma = \inf_{|\lambda - \lambda_{p,n}^\gamma| \geq \Lambda} v_{p,n}(\lambda) - v_{p,n}(\lambda_{p,n}^\gamma) > 0.
$$

The local uniform convergence of $V_{p,n}^m$ to $V_{p,n}$ ensures that

$$
\exists m_\gamma \in \mathbb{N}^*, \forall m \geq m_\gamma, \forall \lambda \text{ s.t. } |\lambda - \lambda_{p,n}^\gamma| \leq \Lambda, \quad |V_{p,n}^m(\lambda) - V_{p,n}(\lambda)| \leq \frac{\gamma}{3}.
$$

For $m \geq m_\gamma$ and $\lambda$ such that $|\lambda - \lambda_{p,n}^\gamma| \geq \Lambda$, we deduce, using the convexity of $V_{p,n}^m$, that

$$
V_{p,n}^m(\lambda) - V_{p,n}^m(\lambda_{p,n}^\gamma) \geq \frac{|\lambda - \lambda_{p,n}^\gamma|}{\Lambda} \left\{ V_{p,n}^m \left( \lambda_{p,n}^\gamma + \frac{\lambda - \lambda_{p,n}^\gamma}{|\lambda - \lambda_{p,n}^\gamma|} \right) - V_{p,n}^m(\lambda_{p,n}^\gamma) \right\}
$$

$$
\geq \frac{|\lambda - \lambda_{p,n}^\gamma|}{\Lambda} \left\{ V_{p,n} \left( \lambda_{p,n}^\gamma + \frac{\lambda - \lambda_{p,n}^\gamma}{|\lambda - \lambda_{p,n}^\gamma|} \right) - V_{p,n}(\lambda_{p,n}^\gamma) - \frac{2\gamma}{3} \right\} \geq \frac{\gamma}{3}.
$$

Since $V_{p,n}^m(\lambda_{p,n}) - V_{p,n}^m(\lambda_{p,n}^\gamma) \leq 0$, we conclude that the above inequality does not hold for $\lambda_{p,n}^m$, which proves that $|\lambda_{p,n}^m - \lambda_{p,n}^\gamma| < \Lambda$ for $m \geq m_\gamma$.

Hence, for $m \geq m_\gamma$, it is sufficient to minimize $V_{p,n}^m$ on the compact set $\{ \lambda : |\lambda - \lambda_{p,n}^\gamma| \leq \Lambda \}$. Now, we can apply [Rubinstein and Shapiro, 1993 Theorem A1 of Chapter 2] to prove that $V_{p,n}^m(\lambda_{p,n}^m)$ converges to $V_{p,n}(\lambda_{p,n}^\gamma)$ a.s. when $m$ goes to infinity. The second assertion of our proposition is discussed right after the proof of Theorem A1 in [Rubinstein and Shapiro, 1993].
Although $V^m_{p,n}$ is not twice differentiable and the classical central limit theorem for sample average approximations cannot be applied, we can study the variance of $V^m_{p,n}(\lambda^m_{p,n})$ and obtain some asymptotic bounds. Before stating our result, we introduce, for $\lambda \in \mathbb{R}^{A_{d,k,n}}$, the notation $M_k(\lambda) = \mathbb{E}[C_{p,n}(\lambda) | \mathcal{F}_{t_k}]$ for $0 \leq k \leq n$. We write $M_k^{(i)}(\lambda)$ for the value computed using the sample $G^{(i)}$.

**Proposition 3.8.** Assume $\lambda^m_{p,n}$ is unique. Then,

$$ \frac{1}{m} \sum_{i=1}^{m} \left( \max_{0 \leq k \leq n} Z_{tk}^{(i)} - M_k^{(i)}(\lambda^m_{p,n}) \right)^2 - V^m_{p,n}(\lambda^m_{p,n})^2 $$

is a convergent estimator of $\mathbb{V}(\max_{0 \leq k \leq n} Z_{tk} - M_k(\lambda^m_{p,n}))$ and moreover if $\lambda^m_{p,n}$ is bounded, $\lim_{m \to \infty} \mathbb{V}(\lambda^m_{p,n}) = \mathbb{V}(\max_{0 \leq k \leq n} Z_{tk} - M_k(\lambda^m_{p,n}))$.

**Proof.** We know that $V^m_{p,n}(\lambda^m_{p,n})$ converges a.s. to $V_{p,n}(\lambda^m_{p,n})$. Following the beginning of the proof of Proposition 3.7, one can easily prove that a.s. the sequence of random functions $\zeta^m : \lambda \mapsto \zeta^m(\lambda) = \frac{1}{m} \sum_{i=1}^{m} \left( \max_{0 \leq k \leq n} Z_{tk}^{(i)} - M_k^{(i)}(\lambda) \right)^2$ converges locally uniformly to the function $\lambda \mapsto \mathbb{E}[\max_{0 \leq k \leq n} Z_{tk} - M_k(\lambda)]^2$. We have already seen that for large enough $m$, we can assume to have solved the optimization problem under a compact constraint. Hence, we deduce that $\frac{1}{m} \sum_{i=1}^{m} \left( \max_{0 \leq k \leq n} Z_{tk}^{(i)} - M_k^{(i)}(\lambda^m_{p,n}) \right)^2$ converges a.s. to $\mathbb{E}[\max_{0 \leq k \leq n} Z_{tk} - M_k(\lambda^m_{p,n})]^2$. This proves the first statement of the proposition.

As $\mathbb{V}(V^m_{p,n}(\lambda^m_{p,n})) = m^{-1} \mathbb{V}(\max_{0 \leq k \leq n} Z_{tk} - M_k(\lambda^m_{p,n}))$, it is sufficient to compute

$$ \mathbb{E} \left[ \left( V^m_{p,n}(\lambda^m_{p,n}) - V^m_{p,n}(\lambda^m_{p,n}) \right)^2 \right] $$

$$ \leq \frac{1}{m} \sum_{i=1}^{m} \mathbb{E} \left[ \max_k \left| M_k^{(i)}(\lambda^m_{p,n}) - M_k^{(i)}(\lambda^m_{p,n}) \right|^2 \right] $$

$$ \leq \frac{1}{m} \sum_{i=1}^{m} \mathbb{E} \left[ \left| \lambda^m_{p,n} - \lambda^m_{p,n} \right|^2 \max_k \left| \tilde{H}^{d} (G_1^{(i)}, \ldots, G_n^{(i)} | \mathcal{F}_{t_k}) \right|^2 \right] $$

$$ \leq \frac{16}{9} \mathbb{E} \left[ \left| \lambda^m_{p,n} - \lambda^m_{p,n} \right|^{1/2} \mathbb{E} \left[ \left| \tilde{H}^{d} (G_1^{(i)}, \ldots, G_n^{(i)}) \right|^{4} \right]^{1/2} \right] $$

where we have used Cauchy Schwartz’ inequality and Doob’s maximal inequality. Then, we easily conclude that $V^m_{p,n}(\lambda^m_{p,n}) - V^m_{p,n}(\lambda^m_{p,n})$ converges to 0 in $L^2$ if $\lambda^m_{p,n}$ is bounded. Hence, $\lim_{m \to \infty} \mathbb{V}(V^m_{p,n}(\lambda^m_{p,n})) = \mathbb{V}(V^m_{p,n}(\lambda^m_{p,n})) = 0$. 

Proposition 3.8 enables us to monitor the variance of our estimator online as for a standard Monte Carlo estimator. Even though the terms involved in $V^m_{p,n}(\lambda^m_{p,n})$ are not independent, the classical variance estimator gives the right result. In practice, one should not feel concerned with the boundedness condition used in the proposition as we know from the proof of Proposition 3.7 that for large enough $m$ we can impose a compactness constraint to the optimization problem without changing its result. Hence, one can pragmatically rely on the proposed variance estimator.
4 The algorithm

Any optimization algorithm requires to repeatedly compute $V_{m}^{p,n}$ and therefore the truncated chaos expansion, which becomes the most time consuming part of our approach as the dimension and/or $p$ increase. A lot of computational time can be saved by considering slightly modified martingales, which only start the first time the option goes in the money.

4.1 An improved set of martingales

We define the first time the option goes in the money by

$$\tau_0 = \inf\{k \geq 0 : Z_{tk} > 0\} \wedge n,$$

which is a $\mathcal{F}$–stopping time and becomes a $\mathcal{G}$–stopping time when the sequence $(Z_{tk})_k$ is $\mathcal{G}$–adapted. To consider martingales only starting once the option has been in the money, we define

$$N_k(\lambda) = \sum_{\ell=1}^{k} (M_{\ell}(\lambda) - M_{\ell-1}(\lambda)) \mathbf{1}_{\ell-1 \geq \tau_0} = (M_{k}(\lambda) - M_{\tau_0}(\lambda)) \mathbf{1}_{k>\tau_0} = M_{k}(\lambda) - M_{k\wedge \tau_0}(\lambda)$$

We easily check that $N(\lambda)$ is a $(\mathcal{F}_k)_{0 \leq k \leq n}$ martingale. It is clear from the proof proposed by Rogers [2002] that in the dual price of a Bermudan option (see (1)) the maximum can be shrunk to the random interval $[\tau_0, n]$. Hence, it is sufficient to consider

$$\inf_{\lambda \in \mathbb{R}^{\otimes_{p,n}}, \lambda_0=0} \mathbb{E}\left[ \max_{\tau_0 \leq k \leq n} (Z_{tk} - M_k(\lambda)) \right].$$

Using Doob’s stopping theorem, we have, for any fixed $\lambda$,

$$\mathbb{E}\left[ \max_{\tau_0 \leq k \leq n} (Z_{tk} - M_k(\lambda)) \right] = \mathbb{E}\left[ \max_{\tau_0 \leq k \leq n} (Z_{tk} - (M_k(\lambda) - M_{\tau_0}(\lambda))) \right] = \mathbb{E}\left[ \max_{\tau_0 \leq k \leq n} (Z_{tk} - N_k(\lambda)) \right].$$

We deduce from this equality that minimizing over either set of martingales $M(\lambda)$ or $N(\lambda)$ leads to the same minimum value and that both problems share the same properties, which justifies why we did not take into account the in–the–money condition for the theoretical study. However, considering the set of martingales $N^\lambda$ is far more efficient from a practical point of view.

In our numerical examples, we modify $V_{p,n}$ and $V_{m}^{m}p,n$ to take into account this improvement and consider instead

$$\tilde{V}_{p,n}(\lambda) = \mathbb{E}\left[ \max_{\tau_0 \leq k \leq n} \left(Z_{tk} - N_k(\lambda)\right) \right]$$

and

$$\tilde{V}_{m,p,n}(\lambda) = \frac{1}{m} \sum_{i=1}^{m} \max_{\tau_0 \leq k \leq n} \left(Z_{tk}^{(i)} - N_k^{(i)}(\lambda)\right).$$

The idea of using martingales starting from the first time the option goes in the money is actually owed to Rogers [2002]. Although he did not discuss it much, this was his choice in the examples he treated.

4.2 Our implementation of the algorithm

To practically compute the infimum of $\tilde{V}_{m,p,n}$, we advise to use a gradient descent algorithm, see Algorithm [1]. The efficiency of such an approach mainly depends on the computation of the
descend direction. When the problem is not twice differentiable, the gradient at the current point is used as a descent direction but it often needs to be scaled, which makes the choice of the step size \( \alpha \) a burning issue to ensure a fast numerical convergence. We refer to Boyd et al. [2003] for a comprehensive survey of several step size rules. After many tests, we found that the step size rule proposed by Polyak [1987] was the best in our context

\[
\alpha = \frac{\tilde{V}_{m}^{p,n}(x_{\ell}) - v^*}{\| \nabla \tilde{V}_{m}^{p,n}(x_{\ell}) \|^2}
\]

where \( v^* \) is the price of the American option we are looking for. In practice, we use the price of the associated European option instead of \( v^* \), which makes \( \alpha \) too large and explains the need of the magnitude factor \( \gamma \). The value of the European price does not need to be very accurate. A decent and fast approximation can be computed with a few thousand samples within few seconds no matter the dimension of the problem.

Algorithm 1: Sample Average Approximation of the dual price

To better understand how this algorithm works, it is important to note that as \( N(\lambda) \) linearly depends on \( \lambda \), \( N(\lambda) = \lambda \cdot \nabla \lambda N(\lambda) \) and therefore both the value function and its gradient are computed at the same time without extra cost. So, \( \nabla \tilde{V}_{m}^{p,n}(x_{\ell+1}) \) is not actually computed on line 9 but at the same time as \( v_{\ell+1/2} \) on line 5.

The HPC approach. Our method targets large problems with as many as several thousands of components for \( \lambda \). This requires to design a scalable algorithm capable of making the most of cluster architectures with hundreds of nodes. At each iteration, the computation of \( \tilde{V}_{p,n}^{m} \) and \( \nabla \tilde{V}_{p,n}^{m} \) is nothing but a standard Monte Carlo method and it inherits from its embarrassingly parallel nature.

A parallel algorithm for distributed memory systems based on the master/slave paradigm is proposed in Algorithm 2. At the beginning, each process samples a bunch of the \( m \) paths (lines 1–3). Then, at each iteration the master process broadcasts the value of \( d_{\ell}, x_{\ell}, \alpha_{\ell} \) and \( \gamma \) (line 7 of Algorithm 1). With these new values, each process computes its contribution to \( \tilde{V}_{p,n}^{m}(x_{\ell} - \gamma \alpha_{\ell} d_{\ell}) \) and \( \nabla \tilde{V}_{p,n}^{m}(x_{\ell} - \gamma \alpha_{\ell} d_{\ell}) \) (lines 8–9) and the Monte Carlo summations are
In parallel do
Generate \((G^{(1)}, Z^{(1)}), \ldots, (G^{(m)}, Z^{(m)})\) \(m\) i.i.d. samples following the law of \((Z, G)\)
end

\[ x_0 \leftarrow 0 \in \mathbb{R}^{A_{p,n}} ; \]
\[ \ell \leftarrow 0, \gamma \leftarrow 1, d_0 \leftarrow 0, v_0 \leftarrow \infty ; \]
while True do
Broadcast \(x_\ell, d_\ell, \gamma, \alpha_\ell;\)
In parallel do
Compute \(\max_{0 \leq k \leq n} (Z_{tk}^{(i)} - N_k^{(i)}(x_\ell - \gamma \alpha_\ell d_\ell))\) for \(i = 1, \ldots, m\)
end
Make a reduction of the above contributions to obtain \(\tilde{V}_{p,n}^{m}(x_\ell - \gamma \alpha_\ell d_\ell)\) and \(\nabla \tilde{V}_{p,n}^{m}(x_\ell - \gamma \alpha_\ell d_\ell)\);
\[ v_{\ell+1/2} \leftarrow \tilde{V}_{p,n}^{m}(x_\ell - \gamma \alpha_\ell d_\ell) ; \]
if \(v_{\ell+1/2} < v_\ell\) then
\[ x_{\ell+1} \leftarrow x_\ell - \gamma \alpha_\ell d_\ell ; \]
\[ v_{\ell+1} \leftarrow v_{\ell+1/2} ; \]
\[ d_{\ell+1} \leftarrow \nabla \tilde{V}_{p,n}^{m}(x_{\ell+1}) ; \]
if \(\frac{v_{\ell+1} - v_\ell}{v_\ell} \leq \varepsilon\) then return;
else
\[ \gamma \leftarrow \gamma / 2 ; \]
end
end

Algorithm 2: Parallel implementation of the Sample Average Approximation of the dual price

obtained by two simple reductions (line 11). Then, the master process tests whether the move is admissible and updates the parameter for the next iteration or returns the solution if the algorithm is not moving enough anymore. This part carried out by the master process is very fast compared to the rest of the code and we dare say that there is no centralized computation in our algorithm. Moreover the communications are reduced to four broadcasts, which guarantees an almost perfect very good scalability. The number of communications is monitored by the number of function evaluations, which remains quite small (between 10 and 20). We study the efficiency of our algorithm on a few examples at the end of Section 5.

Study of the complexity. Most of the computational time is spent computing the martingale part; remember that the cardinality of \(C_{p,n}\) is given by \((nd + p)/(nd + p - 2nd + 1)\). Using martingales only starting once the option has been in the money enables us to only compute the martingale part on paths going in the money strictly before maturity time. Depending on the product, this may allow for saving a lot of computational time. The complexity of one iteration of the loop line 3 in Algorithm 1 is proportional to

\[ \sharp \{\text{paths in the money strictly before } T\} \times \binom{nd + p}{nd}. \]

The payoffs are computed once and for all before starting the descent algorithm. It is worth noting that its computational cost becomes negligible compared to the optimization part when
the dimension of the model or the number of dates increase, the most demanding computation being the evaluation of the martingale decomposition.

5 Applications

5.1 Some frameworks satisfying the assumption of Proposition 3.6

Let \((r_t)_t\) be the instantaneous interest rate supposed to be deterministic.

5.1.1 A put basket option in the multi–dimensional Black Scholes model

The \(d\)–dimensional Black Scholes model writes for \(j \in \{1, \ldots, d\}\)

\[
\begin{align*}
    dS^j_t = S^j_t ((r_t - \delta^j)dt + \sigma^j L_j dB_t)
\end{align*}
\]

where \(W\) is a Brownian motion with values in \(\mathbb{R}^d\), \(\sigma_t = (\sigma^1_t, \ldots, \sigma^d_t)\) is the vector of volatilities, assumed to be deterministic and positive at all times, \(\delta = (\delta^1, \ldots, \delta^d)\) is the vector of instantaneous dividend rates and \(L_j\) is the \(j\)-th row of the matrix \(L\) defined as a square root of the correlation matrix \(\Gamma\), ie. \(\Gamma = LL'\). Moreover, we assume that \(L\) is lower triangular. Clearly, for every \(t\), the random vector \(S_t\) is an element of \(\mathbb{D}^{1,2}\).

The payoff of the put basket option writes as \(\phi(S_t) = (K - \sum_{i=1}^d \omega^i S^i_t)_+\) where \(\omega = (\omega^1, \ldots, \omega^d)\) is a vector of real valued weights. The function \(\phi\) is Lipschitz continuous and hence \(\phi(S_t) \in \mathbb{D}^{1,2}\) for all \(t\). Moreover, for \(s \leq t\) and \(q \in \{1, \ldots, d\}\), we have on the set \(\{\phi(S_t) > 0\}\)

\[
    D^q_s \phi(S_t) = \sum_{j=1}^d \omega^j S^j_t \sigma^j L_{j,q}.
\]

In particular for \(q = d\), we get \(D^d_s \phi(S_t) = \omega^d S^d_t \sigma^d L_{d,d}^d\).

Let \(1 \leq k \leq n\) and \(F\) be a non zero and \(\mathcal{F}_{tk}\)–measurable element of \(\mathcal{C}_{p-1,n}\), ie.

\[
    F = \sum_{\alpha \in A^{p,d}_{p-1,n}} \lambda_\alpha \tilde{H}_\alpha^{\otimes d} (G_1, \ldots, G_n)
\]

for some \(\lambda \in \mathbb{R}^{A^{p,d}_{p-1,n}}\). Let \(1 \leq r \leq k\).

\[
\begin{align*}
    \mathbb{P} \left( \forall t \in [t_{r-1}, t_r], \ D^d_t \phi(S_{tk}) + F = 0 \mid \phi(S_{tk}) > 0 \right) \\
    = \mathbb{P} \left( \forall t \in [t_{r-1}, t_r], \ \omega^d S^d_t \sigma^d L_{d,d} + F = 0 \mid \phi(S_{tk}) > 0 \right) \\
    \leq \frac{\mathbb{P} \left( \forall t \in [t_{r-1}, t_r], \ \omega^d S^d_t \sigma^d L_{d,d} + F = 0 \right)}{\mathbb{P}(\phi(S_{tk}) > 0)}. \tag{17}
\end{align*}
\]

If \(p = 1\), then \(F\) is a deterministic non zero constant. In this case, the numerator vanishes because \(S^d_{tk}\) has a density. Assume \(p \geq 2\), then \(F\) is a multivariate polynomial with global degree \(p-1 \geq 1\). Then we can find \(\ell \in \{1, \ldots, k\}, q \in \{1, \ldots, d\}\) and \(\alpha\) such that \(\alpha^q_\ell \geq 1\) and \(\lambda_\alpha \neq 0\). Let \(\mathcal{G}\) be the sigma algebra generated by \((G^i_j)_{1 \leq i \leq k, 1 \leq j \leq d, (i,j) \neq (\ell,q)}\).

\[
\begin{align*}
    \mathbb{P} \left( \forall t \in [t_{r-1}, t_r], \ \omega^d S^d_t \sigma^d L_{d,d} + F = 0 \right) = \mathbb{E} \left[ \mathbb{P} \left( \forall t \in [t_{r-1}, t_r], \ \omega^d S^d_t \sigma^d L_{d,d} + F = 0 \mid \mathcal{G} \right) \right].
\end{align*}
\]

19
Conditioning on $\hat{G}$, the random variable $\omega^d S^d_t \sigma^d_t L_{d,d} + F$ only depends on $G^q_t$. Consider the algebraic equation for $x \in \mathbb{R}$
\[ a e^{bx+c} = P(x) \] where $(a, b, c) \in \mathbb{R}^3, a \neq 0, b \neq 0$ and $P$ is polynomial with degree $p - 1 \geq 1$. Let $f(x) = a e^{bx+c} - P(x)$, $f'(x) = abP e^{bx+c}$. Clearly, $f'(p)$ never vanishes, which ensures that $f$ has at most $p$ different roots. Hence, we deduce that for any $t \in [t_{r-1}, t_r]$, $\mathbb{P} \left( \omega^d S^d_t \sigma^d_t L_{d,d} + F = 0 \mid \hat{G} \right) = 0$. Combining this result along with (17) proves that Equation (15) holds in this setting.

\[ \begin{align*}
\text{5.1.2 A put option on the minimum of a basket in the multi–dimensional Black Scholes model} \\
\end{align*} \]

We use the notation of the previous example. The payoff of the put option on the minimum of $d$ assets write $\phi(S_t) = (K - \min_j (S^j_t))_+$. One can prove by induction on $d$ that the function $x \in \mathbb{R}^d \mapsto \min_j (x^j)$ is $1$–Lipschitz for the $1$–norm on $\mathbb{R}^d$. Hence, as the positive part function is also Lipschitz, the payoff function $\phi$ is Lipschitz. Then, [Nualart 1998, Proposition 1.2.4] yields that for all $t \in [0, T]$, $\phi(S_t) \in \mathbb{D}^{1,2}$ and for all $q \in \{1, \ldots, d\}$,
\[ D^q(\phi(S_t)) = \sum_{j=1}^d \partial_{x^j} \phi(S_t) D^q(S^j_t) = \sum_{j=1}^d \partial_{x^j} \phi(S_t) S^j_t \sigma^j_t L_{j,q}. \]
With our choice for the matrix $L_d$
\[ D^d(\phi(S_t)) = \partial_{x^d} \phi(S_t) S^d_t \sigma^d_t L_{d,d} = -S^d_t \sigma^d_t L_{d,d} \text{1}_{\phi(S_t) > 0} \text{1}_{\min_j (S^j_t) = S^d_t}. \]

Let $1 \leq k \leq n$ and $F$ be a non zero and $\mathcal{F}_{t_k}$–measurable element of $\mathbb{C}_{p-1,n}$. For $1 \leq r \leq k$,
\[ \mathbb{P} \left( \forall t \in [t_{r-1}, t_r], \ D^d_t \phi(S_{t_k}) + F = 0 \mid \phi(S_{t_k}) > 0 \right) = \mathbb{P} \left( \forall t \in [t_{r-1}, t_r], \ -S^d_t \sigma^d_t L_{d,d} + F = 0 \mid \phi(S_{t_k}) > 0, \ \min_j (S^j_t) = S^d_t \right) \mathbb{P} \left( \min_j (S^j_t) = S^d_t \right) \]
\[ + \mathbb{P} \left( \forall t \in [t_{r-1}, t_r], \ F = 0 \mid \phi(S_{t_k}) > 0, \ \min_j (S^j_t) \neq S^d_t \right) \mathbb{P} \left( \min_j (S^j_t) \neq S^d_t \right) \]
Clearly, the second term in the above sum is zero as $F$ has a density. Hence,
\[ \mathbb{P} \left( \forall t \in [t_{r-1}, t_r], \ D^d_t \phi(S_{t_k}) + F = 0 \mid \phi(S_{t_k}) > 0 \right) \leq \frac{\mathbb{P} \left( \forall t \in [t_{r-1}, t_r], \ -S^d_t \sigma^d_t L_{d,d} + F = 0 \right)}{\mathbb{P}(\phi(S_{t_k}) > 0)}. \]

We conclude as in the case of the put basket option.

\[ \begin{align*}
\text{5.1.3 A put option in the Heston model} \\
\end{align*} \]

The Heston model can be written
\[ dS_t = S_t (r_t dt + \sqrt{\sigma_t} \rho dW^1_t + \sqrt{1 - \rho^2} dW^2_t) \]
\[ d\sigma_t = \kappa (\theta - \sigma_t) dt + \xi \sqrt{\sigma_t} dW^1_t. \]
For $s \leq t$, $D^2_s S_t = S_t \sqrt{1 - \rho^2} \sqrt{\sigma_t}$. Conditionally on $W^1$, $D^2_s S_t$ writes as $a e^{\rho W^2_t + c}$ and we can unfold the same reasoning as after (18).
5.2 Numerical experiments

In this part, we present results obtained from a sequential implementation of our approach as described in Algorithm 1. The computations are run on a standard laptop with an Intel Core i5 processor 2.9 Ghz. For each experiment, we report the price obtained using Algorithm 1 along with its computational time and standard deviation.

5.2.1 Examples in the Black Scholes models

We consider the $d$–dimensional Black Scholes as presented in Section 5.1.1. For the sake of simplicity in choosing the parameters, we have decided to use the same correlation between all the assets, which amounts to considering the following simple structure for $\Gamma$.

$$
\Gamma = \begin{pmatrix}
1 & \rho & \cdots & \rho \\
\rho & 1 & \ddots & \vdots \\
\vdots & \ddots & \ddots & \rho \\
\rho & \cdots & \rho & 1 
\end{pmatrix}
$$

where $\rho \in ]-1/(d-1), 1]$ to ensure that $\Gamma$ is positive definite.

A basket option in the Black–Scholes model. We consider a put option on several assets as presented in Section 5.1.1. We report in Table 1 the price obtained with our approach for $m = 20,000$. The last column reference price corresponds to the prices reported in Schoenmakers et al. [2013] on the same examples. These reference prices were obtained within a few minutes according to the authors whereas here we manage to get similar values within a few seconds. We can see that a second order chaos expansion, $p = 2$, already gives very accurate results within a few tenths of a second for a 5–dimensional problem with 6 dates, which proves the impressive efficiency of our approach.

Table 1: Prices for the put basket option with parameters $T = 3$, $r = 0.05$, $K = 100$, $\rho = 0$, $\sigma^j = 0.2$, $\delta^j = 0$, $d = 5$, $\omega^j = 1/d$.

A call on the maximum of $d$ assets in the Black–Scholes model. We consider a call option on the maximum of $d$ assets in the Black Scholes model. As in the previous example, the last column reference price corresponds to the prices reported in Schoenmakers et al. [2013] on the same examples. With no surprise, the computational times reported in Table 2 increase exponentially with the dimension $n \times d$ and the degree $p$. Whereas a second order
expansion provides very accurate results for the basket option, it only gives a rough upper-bound for the call option on the maximum of \( d \) assets. Considering a third order expansion \( p = 3 \) takes far longer but enables us to get very tight upper-bounds.

**A geometric basket option in the Black–Scholes model** Benchmarking a new method on high dimensional products becomes hardly feasible as almost no high dimensional American options can be priced accurately in a reasonable time. An exception to this is the geometric option with payoff \( (K - \left( \prod_{j=1}^{d} S_j \right)^{1/d})_+ \) for the put option. Easy calculations show that the price of this \( d \)-dimensional option equals the one of the 1-dimensional option with parameters

\[
\hat{S}_0 = \left( \prod_{j=1}^{d} S_0^j \right)^{1/d}; \quad \hat{\sigma} = \frac{1}{d} \sqrt{\sum_{i,j} \sigma^i \sigma^j \Gamma_{ij}}; \quad \hat{\delta} = \frac{1}{d} \sum_{j=1}^{d} \left( \hat{\delta}^j + \frac{1}{2} (\sigma^j)^2 \right) - \frac{1}{2} (\hat{\sigma})^2.
\]

Table 3 summarizes the correspondence values used in the examples.

Table 3: Correspondence table for the parameters of the geometric options with \( \hat{\delta}^j = 0 \).

The 1–\( d \) price is computed using a tree method with several thousand steps. We can see in Table 4 that a second order approximation gives very accurate result within a few seconds for an option with 10 underlying assets, which proves the efficiency of our approach. We cannot beat the curse of dimensionality, which slows down of algorithm for very large problems. For an option on 40 assets, we obtain a price up to a 3% relative error within 3 minutes which is already very fast for such a high dimensional problem. The number of terms involved in the chaos expansion can become very large: for \( d = 40 \) and \( p = 2 \), there are 65340 elements in \( \mathcal{C}_{p,n} \). Even though we are not working in a linear algebra framework, it is advisable to ensure that the number of samples \( m \) used in the sample average approximation is larger than the number of free parameters in the optimization problem. When \( m \) becomes too small, we may

face an over-fitting phenomenon as the number of parameters is far too large compared to the information contained in the sample average approximation. This probably explains why the price obtained for $p = 2$, $d = 40$ and $m = 40$ is slightly smaller than the true price.

In the next paragraph, we test the scalability of Algorithm 2 on this particular examples for a larger number of samples.

### 5.2.2 Scalability of the parallel algorithm

We consider the 40-dimensional geometric put option studied in Table 4 with $p = 2$ and test the scalability of our parallel implementation for $m = 200,000$. The tests are run on a BullX DLC supercomputer containing 190 nodes for a total of 3204 CPU cores. We report in Table 5 the results of our scalability study using from 1 to 512 cores. Despite the two levels of parallelism available on this supercomputer, we have used a pure MPI implementation without any reference to multithread programming. We could probably have improved the efficiency a bit using two levels of parallelism, but the results are already convincing enough and do not justify the need of a two level approach, which makes the implementation more delicate. The sequential Algorithm runs within one hour and a quarter whereas using 512 cores we manage to get the computational time down to a dozen of seconds, which corresponds to a 0.6 efficiency. Considering the so short wall time required by the run on 512 cores, keeping the efficiency at this level represents a great achievement. Note that with 128 cores, the code runs within a minute with an efficiency of three quarters. These experiments prove the impressive scalability of our algorithm.

### 6 Conclusion

We have proposed a purely dual algorithm to compute the price of American or Bermudan options using some stochastic optimization tools. The starting point of our algorithm is the use of Wiener chaos expansion to build a finite dimensional vector space of martingales. Then, we rely on a sample average approximation to effectively optimize the coefficients of the expansion. Our algorithm is very fast: for problems up to dimension 5, a price is obtained within a few seconds, which is a tremendous improvement compared to existing purely dual methods. For higher dimensional problems, we can use a very scalable parallel algorithm to tackle very high dimensional problems (40 underlying assets). We can transparently deal with complex path-dependent payoffs without any extra computational cost. Even though, we restricted to a Brownian setting in this work, our approach could easily be extended to

jump diffusion models by introducing Poisson chaos expansion, which is linked to Charlier polynomials (see [Geiss and Labart 2016]). We believe that our approach could be improved by cleverly reducing the number of terms in the chaos expansion, the computation of which centralizes most of the effort.
