Introduction

Phoneme categorization

• Infants show discrimination of syllables as soon as 1 month of age despite speaker variability (Eimas et al., 1971; Eimas, 1974).

• Problem of invariance: ability to detect a consonant in ≠ syllable contexts despite acoustic variations: argument for the Motor Theory (Liberman et al., 1967).

• A recent study claimed that 6-month olds but not 3-month olds solve the invariance problem (Hochmann et al., 2014) and argue against a motor interpretation since babbling occurs later.

  - Standard: (baseline) bead-bad-boat (target) boo
  - Deviant: (baseline) bead-bad-boat (target) due

Greater pupil dilatation for the deviant target than for the standard target.

However

• Are infants detecting invariance or just acoustic differences between stimuli?
• Does babbling only start at 6 months?

Goals of the present study

• Assess the ability to detect invariants and the role of motor knowledge in 6-to 12-month old infants.

Methods

Participants: 41 6- to 12-month old infants.
• 12 6months (8M), mean age = 6.45, sd= 0.1.
• 14 9mo (7M), mean age= 9.47, sd= 0.16.
• 15 12mo (6M), mean age= 12.48, sd=0.19.

Intersensory matching procedure (Pons et al., 2009)

Parental questionnaire assessing infants’ production abilities
29 infants out of 41: 6 6mo, 11 9mo, 12 12mo

Hypotheses

• If infants have plosive categories they should associate the sound in one vocalic context with the visual gesture in another vocalic context
• If motor knowledge plays a role this should vary according to babbling abilities

Analysis: intersensory matching

• % Looking Time (LT) for Baseline (1&2) and for Test (4&6).
• Difference score = %LT Test – %LT Baseline.

Analysis: production

Infants were classified as:
• No Babbling: no syllable or monosyllable
• Canonical Babbling: reduplicated CVCVCV with /a/
• Variegated Babbling: CVCVCV with different vowels

Preliminary Results

Effect of Age

• Plosive categorization abilities (p<0.05): preference for stimulus presented during familiarization (Trials 3&5).
• Significant for 6-mo (p<0.05), trend toward significance for 9-mo olds. (p=0.07).
• No significant between-groups difference.

Effect of Production abilities

Non Babbling: 7 infants (4 6mo, 2 9mo, 1 12mo).
Canonical Babbling: 15 infants (2 6mo, 9 9mo, 4 12mo)
Variegated Babbling: 7 infants (1 6mo, 4 9mo, 2 12mo)

• No matching for NonBabbling & Canonical infants (p>0.05).
• Trend toward significant matching for Variegated infants (p=0.09).
• Trend toward better matching for Variegated than NonBabbling infants (p=0.06).

Interaction Age by Production abilities

Conclusion

• Infants showed a preference for videos pronouncing the consonant with which they had been familiarized.
• They performed intersensory matching in spite of the varying vowel context (invariance for plosive place of articulation?)
• This performance seems to be present from 6 months of age comforting Hochmann et al.’s results
• Effect of production abilities: infants producing [b] and/or [d] with varying vowels are better at matching than infants who don’t produce the contrast, or who only produce the contrast with a single vowel.
• Role of the perceptuo-motor link in categorization?
• No association in 12-month old infants: inadequate procedure? Emergence of the preference for new stimuli at 12mo?
