Abstract

An axiomatisation of Nominal Kleene Algebra has been proposed by Gabbay and Ciancia, and then shown to be complete and decidable by Kozen et al. However, one can think of at least four different formulations for a Kleene Algebra with names: using freshness conditions or a presheaf structure (types), and with explicit permutations or not. We formally show that these variations are all equivalent.

Then we introduce an extension of Nominal Kleene Algebra, motivated by relational models of programming languages. The idea is to let letters (i.e., atomic programs) carry a set of names, rather than being reduced to a single name. We formally show that this extension is at least as expressive as the original one, and that it may be presented with or without a presheaf structure, and with or without syntactic permutations. Whether this extension is strictly more expressive remains open.

All our results were formally checked using the Coq proof assistant.

Keywords and phrases Nominal sets, Kleene algebra, equational theory, Coq

1 Introduction

Gabbay and Ciancia introduced a nominal extension of Kleene algebra [3], as a framework for trace semantics with dynamic allocation of resources. The associated semantics extends formal languages into nominal languages, where words have a nominal structure. Kozen et al. recently proved the completeness of the proposed axiomatisation [6], and proposed a coalgebraic treatment [5] yielding decidability of the equational theory.

They use the following syntax for nominal regular expressions:

\[ e, f ::= a \in \Sigma \mid 0 \mid 1 \mid e + f \mid e \cdot f \mid e^* \mid \nu a.e \]

where \(\Sigma\) is the alphabet, and \(\nu a.e\) makes it possible to generate a fresh letter (or name) \(a\) before continuing as \(e\). For instance, the expression \(\nu a.\nu b.((a \cdot b))\) denotes the language of all words of length two consisting of two distinct letters.

While such a syntax is natural from a nominal point of view, other choices are possible. For instance, one might expect expressions to be typed or classified according to their set of free names. Similarly, name permutations, which are available in any model, can be reified at the syntactic level. We first list four axiomatisations of the corresponding presentations—one of them corresponding to Gabbay and Ciancia’s axiomatisation, and we prove that all choices are in fact equivalent. For the sake of the proofs, we need to introduce the positive fragments, where the constant 0 denoting the empty language is excluded; these fragments are interesting.

\(^*\) This author was funded by the European Research Council (ERC) under the European Union’s Horizon 2020 programme (CoVeCe, grant agreement No 678157); this work has also been supported by the project ANR 12IS02001 PACE.
because they are stable: any proof of an equality whose members belong to the fragment only uses expressions from that fragment.

Kleene algebra are known to be complete not only with respect to language models, but also relational models. There, the letters from the alphabet are interpreted as binary relations, and the regular operations correspond to standard operations on binary relations: union, composition, reflexive transitive closure. This makes it possible to interpret imperative programs, seen as state transformers: binary relations between memory states. Kozen actually designed an extension of Kleene algebra, Kleene algebra with tests [4], which makes it possible to represent not only the control flow of such programs, but also the tests and conditions appearing in while loops and branching statements.

Extending Kleene algebra with names seems appropriate to model imperative programs with local variables, where parts of the memory is visible only locally. The previous notion of nominal Kleene algebra is however not really appropriate for this purpose: letters of the alphabet (i.e., atomic programs, instructions) are equated with names bound by the \( \nu \alpha \) construct (i.e., memory locations). In contrast, the instruction \( x \leftarrow y \) that assigns to variable \( x \) the value of variable \( y \) should be an elementary construction depending on the names \( x \) and \( y \). For this reason, we provide an extension of the syntax where letters carry a list of names. (We could use arbitrary nominal sets, but we restrict to a concrete representation in this work for the sake of simplicity.) The typed version of this extension is more appropriate for modelling imperative programs with local variables; like above for plain nominal Kleene algebra, we show that the various presentations are equivalent. We moreover show that the extension is conservative: plain nominal Kleene algebra can be encoded into the extended ones. Whether a converse encoding is possible remains open.

Outline.

We define the various theories in Section 2 and we compare them in Section 3. In Section 4 we provide a relational interpretation for our extended model. We conclude in Section 5.

Notation.

We write \( \mathcal{P}_f (A) \) for the set of finite subsets of \( A \). The set of natural numbers is written \( \mathbb{N} \). Composition of two functions \( f \) and \( g \) is written \( f \circ g \); it maps \( x \) to \( f (g(x)) \).

2 Expressions and proofs

2.1 Atoms and letters

Let \( \mathcal{A} \) be an infinite set of atoms with decidable equality. We consider in this paper finitely supported permutations of atoms, simply called permutations in the following. They are bijections \( \pi \) such that there is a finite set \( A \subseteq \mathcal{A} \) such that \( a \in A \Rightarrow \pi(a) = a \). The inverse of a permutation \( \pi \) is written \( \pi^{-1} \). The identity permutation is denoted by \( () \), and the permutation exchanging \( a \) and \( b \), and leaving every other atom unchanged, is written \( (a \ b) \). Finally, if \( \pi \) is a permutation and \( A \) is a finite set of atoms, \( \pi(A) := \{ \pi(a) \mid a \in A \} \) is the image of \( A \) under \( \pi \).

We consider as letters an arbitrary nominal set \( \mathcal{L}[2, 7] \), which we assume to be decidable. Such a set is specified through the data of its set of elements, a function \( \xi() : \mathcal{L} \rightarrow \mathcal{P}_f (A) \) mapping every element to its support, and an action of the group of permutations on \( \mathcal{L} \).
These functions must satisfy the following axioms:

\[
\begin{align*}
\forall x \in \mathcal{L}, \forall \pi, (\forall a \in \mathcal{L}(x), \pi(a) = a) \Rightarrow \pi(x) = x. \\
\forall x \in \mathcal{L}, \forall \pi, \pi(\mathcal{L}(x)) = \pi(\mathcal{L}(x)). \\
\forall x \in \mathcal{L}, \forall \pi, \pi'(\mathcal{L}(x)) = \pi \circ \pi'(\mathcal{L}(x)).
\end{align*}
\]

(1) (2) (3)

2.2 Expressions and sets of expressions

We define a single type for expressions, containing all possible operators, and we define several fragments of it afterwards. Doing so makes it possible to share several definitions, enabling important code-reuse in our proof scripts.

- **Definition 1 (Expressions).** The set $E$ of expressions is composed of terms formed over the following syntax, where the letter $A$ is a finite set of atoms, $\pi$ denotes a permutation, $a$ is an atom and $l$ is a letter:

$$e, f := 0 \mid 1 \mid e + f \mid e \cdot f \mid e^* \mid \nu_a.e \mid l \mid a \mid \langle \pi \rangle e \mid \bot A \mid id_A \mid w_a.e.$$ 

Product $\cdot$, sum $+$ and Kleene star $^*$ are the regular operations, together with the associated constants 0 and 1. $\nu_a$ is name restriction. Variables can be either letters $l$ or atoms $a$. We include a syntactic construction for explicit permutations $\langle \pi \rangle$. The remaining entries ($\bot A$, $id_A$, and $w_a$) are for the presheaf presentation; we discuss them in Section 2.2.2.

2.2.1 Untyped expressions

- **Definition 2 (Untyped expression).** An expression $e$ is **untyped** if it neither contains the operator $w_a$ nor the constants $\bot A$ and $id_A$. The set of untyped expressions is written $U$.

We define freshness only for untyped expressions:

- **Definition 3 (Freshness).** An atom $a$ is **fresh for** $e$ if the judgement $a \# e$ can be inferred in the following system.

$$\begin{array}{cccc}
a \# 1 & a \# l & a \# b & a \# e + f \\
a \# e & a \# f \\
a \# e & a \# e^* & a \# \nu_a.e & a \# \langle \pi \rangle e.
\end{array}$$

Accordingly, the **support** of an untyped expression $e$, written $\mathcal{L}(e)$, is the unique set such that $\forall a, a \# e \iff a \notin \mathcal{L}(e)$.

2.2.2 Typed expressions

For the presheaf approach, we replace freshness assumptions with type derivations. In order to enforce uniqueness of types, we replace the constants 0 and 1 from the untyped syntax by the annotated constants $\bot A$ and $id_A$, and we use explicit weakenings ($w_a$).

- **Definition 4 (Typed expressions).** For any $e \in E$ and $A \in \mathcal{P}_f(A)$, $e$ **has the type** $A$ if the judgement $e : A$ can be inferred in the following system:

$$\begin{align*}
\text{id}_A : A & \quad \bot_A : A & \quad l : \mathcal{L}(l) & \quad a : \mathcal{A} & \quad e : A \cdot f : A \\
e : A & \quad e : A & \quad a \notin A & \quad e : A \setminus \{a\} & \quad e : A / a \quad e : \pi^{-1}(A) \\
e \cdot f : A & \quad e^* : A & \quad \nu_a.e : A & \quad w_a.e : A & \quad \langle \pi \rangle e : A
\end{align*}$$
If this is the case, then \( e \) is typed. The set of typed expressions is written \( T \).

- **Remark.** This type system is syntax directed and yields a simple decision procedure.

### 2.2.3 Expressions over letters or atoms

A significant motivation for this work was to study the differences between having atoms or letters as variables in expressions. Hence we define two other subsets.

- **Definition 5** (Atomic expressions, literate expressions). An expression \( e \) is called atomic (respectively literate) if it does not contain letters (respectively atoms) as variables. The set of atomic expressions is \( E(A) \), and the set of literate expressions is \( E(L) \).

Intuitively, there are two main differences between having atoms or letters as variables. First, a letter may depend on many atoms. Second, two letters with the same support can still be different, whereas the following equivalence holds:

\[
\forall a, b \in A, \ a = b \iff (\forall c \in A, \ c \neq a \iff c \neq b).
\]

### 2.2.4 Positive expressions

For the sake of proofs, we also define the classes of expressions without \( 0 \) or \( \bot_A \) as a sub-expression. A motivation for excluding these is that in any reasonable system \( 0 \equiv 0 \cdot e \). Hence if there is an atom \( a \) not fresh for \( e \), we would have two equivalent expressions with different sets of fresh variables.

- **Definition 6** (Positive expression). An expression \( e \) is positive if it does not contain \( 0 \) nor \( \bot_A \) as a sub-expression. The set of positive expressions is \( E^+ \).

For conciseness, we write \( E^+(L) \) for \( E(L) \cap E^+ \), and \( E^+(A) \) for \( E(A) \cap E^+ \).

### 2.2.5 Explicit permutations

Our syntax includes for explicit permutations \( \pi \), while permutations are usually considered as external operations. This allows one to manipulate permutations inside the expressions, and we shall see that this addition does not raise the complexity of the problem.

Nevertheless, we need to formally define the semantics of permutations on expressions.

- **Definition 7** (Action of a permutation on an expression). Let \( e \in E \) be an expression and \( \pi \) a permutation. The action of \( \pi \) on \( e \), written \( \pi \cdot e \), is defined as follows:

\[
\begin{align*}
\pi \cdot 1 & := 1 \\
\pi \cdot 0 & := 0 \\
\pi \cdot \text{id}_A & := \text{id}_{\pi(A)} \\
\pi \cdot \bot_A & := \bot_{\pi(A)} \\
\pi \cdot a & := \pi(a) \\
\pi \cdot l & := \pi(l) \\
\pi \cdot (e^\ast) & := (\pi \cdot e)^\ast \\
\pi \cdot (e \cdot f) & := \pi \cdot e \cdot \pi \cdot f \\
\pi \cdot (e + f) & := \pi \cdot e + \pi \cdot f
\end{align*}
\]

Expressions without explicit substitutions are called *clean*.

- **Definition 8** (Clean expressions). An expression \( e \) is clean if it never uses the operator \( (\pi) \). The set of clean expressions is \( C \).

Applying permutations preserves all classes we have listed so far:
\[
\begin{align*}
Ax \vdash f = e & \quad Ax \vdash e = f & \quad Ax \vdash f = g & \quad Ax \vdash (e, f) \in Ax
\end{align*}
\]

(a) Equivalence and axiom rules.

\[
\begin{align*}
Ax \vdash 0 = 0 & \quad Ax \vdash 1 = 1 & \quad Ax \vdash id_A = id_A & \quad Ax \vdash 1_A = 1_A \\
Ax \vdash l = l & \quad Ax \vdash a = a & \quad Ax \vdash e = g & \quad Ax \vdash f = h & \quad Ax \vdash e = g & \quad Ax \vdash f = h \\
Ax \vdash e = e' & \quad Ax \vdash \nu_a.e = \nu_a.f & \quad Ax \vdash w_a.e = w_a.f & \quad Ax \vdash (\pi) e = (\pi) f
\end{align*}
\]

(b) Congruence rules.

\[
\begin{align*}
Ax \vdash e + f = f + e & \quad Ax \vdash e + (f + g) = (e + f) + g & \quad Ax \vdash e + e = e \\
Ax \vdash e \cdot (f + g) = (e \cdot f) + (e \cdot g) & \quad Ax \vdash (e + f) \cdot e = (e \cdot g) + (f \cdot g) \\
Ax \vdash e \cdot (f \cdot g) = (e \cdot f) \cdot g & \quad Ax \vdash f + e \cdot g \leq g & \quad Ax \vdash e \cdot f \leq g & \quad Ax \vdash f \cdot e' \leq g & \quad Ax \vdash f + g \cdot e \leq g
\end{align*}
\]

(c) Constant-free Kleene algebra axioms.

Table 1 Modular deduction system

\[\text{Lemma 9. For any subset of expressions } S \text{ chosen from } \{T, U, E(A), E(L), E^*, C\}, \text{ for any permutation } \pi, \text{ and for any expression } e \in E, e \in S \iff \pi \circ e \in S. \text{ Furthermore, if } e \text{ has the type } A \text{ then } \pi \circ e : \pi(A), \text{ and if } a \text{ is fresh for } e \text{ then } \pi(a) \neq \pi \circ e.\]

(Note the equivalence in the first point, which is why we keep a residual empty permutation when we apply a permutation to an expression of the shape \((\pi) e\).)

2.3 Proofs

A generic framework for proofs

We now describe a generic framework for defining equational theories over \(E\). Given a relation \(Ax \subseteq E \times E\), we define the judgement \(Ax \vdash e = f\) to hold if it can be inferred in the system displayed in Table 1 (where \(Ax \vdash e \leq f\) is a shorthand for \(Ax \vdash e + f = f\)). Notice that we have “hardwired” some laws of Kleene Algebra (KA) in this system, on the basis that they should hold for any reasonable equational system for Nominal Kleene Algebra. However, as we have two sets of constants, we cannot put inside the generic system the Kleene Algebra laws dealing with them. For instance when we consider expressions over the untyped syntax, the fact that \(e \cdot 1 = e\) will be stated inside \(Ax\). It is a simple matter to check that whatever \(Ax\), the relation \(Ax \vdash _-_ = _-_\) is an equivalence relation and \(Ax \vdash _-_ \leq _-_\) is a preorder.
Sets of axioms

In Tables 2-6, we present a number of possible sets of axioms, which may be combined to axiomatise the different subsets we consider. All the axioms displayed here are implicitly universally quantified.

The first groups of axioms correspond to the axioms of KA for 1, declined in a typed and an untyped fashion. We then do the same for 0 and \(\perp\), first with the KA axioms, and then for its interactions with \(\langle\pi\rangle\), \(\nu\), and \(w\), always separating between the typed and untyped cases. These sets of axioms for constants are presented in Tables 2 and 3.

We then introduce sets of axioms to handle permutations. The axiom propagating \(w\) is set apart, as it only makes sense for typed expressions. This group is displayed in Table 4. Notice that no law speaks about zeros, as it already has been dealt with in (3a).

The sets of axioms in Table 5 are simple distributive laws of the restriction and weakening operators. The next group, displayed in Table 6, constitutes the core of the nominal theory of expressions. The untyped axioms are mostly the classic nominal axioms, taken from [6]. The only new axiom here is (6b), where we use syntactic permutations rather than semantic ones. The typed axioms are for the most part straightforward reformulations of the previous ones. Notice that in the typed case, we do not need to use freshness conditions, but rather typing statements. The last law of the set (6f) reflects the fact that for an untyped expression \(e\), if \(a \neq b\) then \(a \# e \iff a \# \nu_b.e\).

2.4 Theories

A theory is given by a relation \(Ax\), listing the axioms, and a set \(S\) from which we take expressions. As expressions may be typed or untyped, atomic or literate, clean or not and positive or not, there are 16 theories, listed in Table 7.

Notice that every subset of expressions mentioned in this table is associated with a single theory. In the following, for concision, we may refer to a theory by simply giving its base set. It is also worth mentioning that for every set \(S\), the theories for \(E\cap S\) and \(E\cap T\) use the same set of axioms.

The theory \(E(\mathcal{A})\cap U\cap C\) corresponds precisely to the axiomatisation of NKA given in [6]. In our view, the best theory for defining the interpretation of a program would be \(E^+(\mathcal{L})\cap U\cap C\), but a relational interpretation is best defined in \(E^+(\mathcal{L})\cap T\).

A difficulty is that if we have a theory \((S, Ax)\), with two expressions \(e, f \in S\) such that \(Ax \vdash e = f\), it may be the case that the proof uses expressions outside of \(S\). This is generally what happens in systems with 0 (or \(\perp\)): if \(e \notin S\) and \(0 \in S\), then:

\[
\begin{align*}
Ax \vdash 0 \cdot e & \quad Ax \vdash 0 \cdot e = 0 \\
\hline
Ax \vdash 0 = 0 & 
\end{align*}
\]

This is a bad property when one wants to prove results by structural induction on proofs. This phenomenon disappears with stable theories:

\textbf{Definition 10.} A theory \((S, Ax)\) is stable if for any expressions \(e, f \in E\) such that \(Ax \vdash e = f\), \(e \in S\) if and only if \(f \in S\).

All of our positive theories (those included in \(E^+\)) are stable.
Untyped identity axioms

\[ e \cdot 1 = e \]
\[ 1 \cdot e = e \]
\[ 1 + e \cdot e^* \not\leq e^* \]
\[ 1 + e^* \cdot e \not\leq e^* \]

(a) Untyped identity axioms

\[ e \cdot id_A = e \] (if \( e : A \))
\[ id_A \cdot e = e \] (if \( e : A \))
\[ id_A + e \cdot e^* \not\leq e^* \] (if \( e : A \))
\[ id_A + e^* \cdot e \not\leq e^* \] (if \( e : A \))

(b) Typed identity axioms

Table 2 Identity axioms

General permutation axioms

\[ \langle \pi \rangle (e + f) = \langle \pi \rangle e + \langle \pi \rangle f \]
\[ \langle \pi \rangle (e \cdot f) = \langle \pi \rangle e \cdot \langle \pi \rangle f \]
\[ \langle \pi \rangle (e^*) = ((\langle \pi \rangle e)^*) \]
\[ \langle \pi \rangle (\nu_a e) = \nu_{\pi(a)} \cdot \langle \pi \rangle e \]
\[ \langle \pi \rangle (\pi') e = \langle \pi \circ \pi' \rangle e \]
\[ \langle \pi \rangle 1 = 1 \]
\[ \langle \pi \rangle id_A = id_{\pi(A)} \]
\[ \langle \{ \} \rangle e = e \]
\[ \langle \pi \rangle a = \pi (a) \] (if \( a \in A \))
\[ \langle \pi \rangle l = \pi (l) \] (if \( l \in \mathcal{L} \))

(a) General permutation axioms

\[ \langle \pi \rangle (w_a e) = w_{\pi(a)} \cdot \langle \pi \rangle e \]

(b) Permutation vs. \( w_a \)

Table 4 Permutation axioms

Typed zero axioms

\[ e + 0 = e \]
\[ e \cdot 0 = e \] (if \( e \in \mathbb{U} \))
\[ 0 \cdot e = e \] (if \( e \in \mathbb{U} \))
\[ (\pi) 0 = 0 \]
\[ \nu_a 0 = 0 \]

(a) Untyped zero axioms

\[ e + 1_A = e \] (if \( e : A \))
\[ e \cdot 1_A = e \] (if \( e : A \))
\[ 1_A \cdot e = e \] (if \( e : A \))
\[ (\pi) 1_A = 1_{\pi(A)} \] (if \( a \in A \))
\[ \nu_a 1_A = 1_{\pi A(a)} \] (if \( a \notin A \))

(b) Typed zero axioms

Table 3 Zero axioms

Distributive laws of \( \nu_a, w_a \)

\[ w_a \cdot (e + f) = w_a \cdot e + w_a \cdot f \]
\[ w_a \cdot (e^*) = (w_a \cdot e^*) \]
\[ w_a \cdot (e \cdot f) = w_a \cdot e \cdot w_a \cdot f \]
\[ w_a \cdot (id_A) = id_{\pi A(a)} \] (if \( a \notin A \))
\[ w_a \cdot (w_b e) = w_b \cdot (w_a e) \]

(a) Weakening

\[ \nu_a \cdot (e + f) = \nu_a \cdot e + \nu_a \cdot f \]
\[ \nu_a \cdot (\nu_b e) = \nu_b \cdot (\nu_a e) \]

(b) Restriction

Table 5 Distributive laws of \( \nu_a, w_a \)
\[ \nu_b.e = \nu_a.(a \ b) \eta e \] (if \(a \neq e\))

\[ \nu_a.e = e \] (if \(a \neq e\))

\[ \nu_b.e = \nu_a.(a \ b) \cdot e \] (if \(a \neq e\))

\[ \nu_a.f \cdot e = \nu_a.(f \cdot e) \] (if \(a \neq e\))

\[ e \cdot \nu_a.f = \nu_a.(e \cdot f) \] (if \(a \neq e\))

\[ \nu_a.e = e \] (if \(a \neq e\))

\[ \nu_a.w.a.e = w.a.(\nu_a.e) \] (if \(a \neq b\))

\[ \nu_a.e = e \] (if \(a \neq e\))

\[ \nu_a.w.a.e = w.a.(\nu_a.e) \] (if \(a \neq b\))

\[ \nu_a.e = e \] (if \(a \neq e\))

\[ \nu_a.w.a.e = w.a.(\nu_a.e) \] (if \(a \neq b\))

\[ \nu_a.e = e \] (if \(a \neq e\))

\[ \nu_a.w.a.e = w.a.(\nu_a.e) \] (if \(a \neq b\))

\[ \nu_a.e = e \] (if \(a \neq e\))

\[ \nu_a.w.a.e = w.a.(\nu_a.e) \] (if \(a \neq b\))

\[ \nu_a.e = e \] (if \(a \neq e\))

\[ \nu_a.w.a.e = w.a.(\nu_a.e) \] (if \(a \neq b\))

\[ \nu_a.e = e \] (if \(a \neq e\))

\[ \nu_a.w.a.e = w.a.(\nu_a.e) \] (if \(a \neq b\))

**Table 7** Theories
We summarise the results we obtained using Coq on Figure 1. (The scripts are available online [1].) A plain arrow is drawn between two theories if the source of the arrow can be embedded into the target of the arrow, and a dashed arrow when the source reduces to the target. Thanks to the decidability result for \( E(A) \cap U \cap C \) [5], this ensures that all atomic theories are decidable.

We discuss in more details how we obtained some of these results.

### 3.2.1 Reducing to positive fragments

The first step consists in getting rid of the constants 0 and \( 1_A \), so that we can focus on stable theories (Definition 10). We only present here the untyped case. In other words we choose a
theory \((S,Ax)\), with \(S\) taken from the set \(\mathbb{E}(A)\cap \mathbb{U}, \mathbb{E}(A)\cap (\mathbb{U}\cap \mathbb{C}), \mathbb{E}(L)\cap \mathbb{U}, \mathbb{E}(L)\cap (\mathbb{U}\cap \mathbb{C})\), the corresponding positive theory being \((S\cap \mathbb{E}^+,Ax\setminus (3a))\).

- **Definition 14.** If \(e\) is an untyped expression, \(\text{extract}(e)\) is the unique normal form of \(e\) with respect to the following confluent rewriting system:

\[
\begin{align*}
e + 0 & \rightarrow e & 0 + f & \rightarrow f & e \cdot 0 & \rightarrow 0 & 0 \cdot f & \rightarrow 0 & \nu_a.0 & \rightarrow (\pi)0 & \rightarrow 0 & 0^* & \rightarrow 1.
\end{align*}
\]

The interesting property of this function is that if \(Ax\vdash e = 0\), then \(\text{extract}(e)\) is syntactically equal to 0, and \(\text{extract}(e)\in \mathbb{E}^+\) otherwise. Furthermore, for every \(e\in S\), \(Ax\vdash \text{extract}(e) = e\).

The formal proof then relies on two key observations:
1. If \((e,f)\in Ax\setminus (3a)\), then \(Ax\setminus (3a)\vdash \text{extract}(e) = \text{extract}(f)\).
2. If \((e,f)\in (3a)\), then \(\text{extract}(e) = \text{extract}(f)\).

This allows to prove by induction on proofs that:
\[
Ax\vdash e = f \Rightarrow Ax\setminus (3a)\vdash \text{extract}(e) = \text{extract}(f).
\]

Because the positive axiomatisation is included in \(Ax\), we also get:
\[
Ax\setminus (3a)\vdash \text{extract}(e) = \text{extract}(f) \Rightarrow Ax\vdash \text{extract}(e) = \text{extract}(f).
\]

The fact that \(\text{extract}(e)\) is provably equal to \(e\) with the axioms \(Ax\) allows to close the proof of equivalence, with the entailment:
\[
Ax\vdash \text{extract}(e) = \text{extract}(f) \Rightarrow Ax\vdash e = f.
\]

However, if \(Ax\vdash e = 0\) then \(\text{extract}(e) \notin \mathbb{E}^+\). This means that we cannot directly use \(\text{extract()}\) as an embedding between theories. We obtain the reduction as follows: when given the pair \(e,f\), we compute \(\text{extract}(e)\) and \(\text{extract}(f)\). If both of these are equal to zero, then when map the pair to equal positive expressions, say 1, 1. If both of them are non-zero, then we produce \(\text{extract}(e),\text{extract}(f)\). Otherwise we produce different positive expressions, say 1, \(a\) in the atomic case and 1, \(l\) in the literate case.

### 3.2.2 From presheaves to freshness, and back

Let \((S,Ax)\) be a positive untyped theory, meaning \(S\subseteq \mathbb{E}^+\cap \mathbb{U}\), and \((S',Ax')\) be the corresponding positive typed theory. We show here how to transport \(S\) into \(S'\), and vice versa. This corresponds to the vertical arrows on Figure 1. The key tools in this case are the erasure and retyping functions.

- **Definition 15 (Erasure).** The erasure of \(e\in \mathbb{T}\), written \([e]\), is the expression obtained from \(e\) by removing all weakenings \((w_a)\), and replacing all \(id_A\) with 1 and all \(\bot_A\) with 0.

- **Lemma 16.** If \(e\in S'\) then \([e]\in S\), and if \(e:A\) then \(\frac{1}{2}([e])\subseteq A\).

- **Definition 17 (Retyping).** Let \(e\in \mathbb{U}\), we define the retyping of \(e\), written \([e]\), by structural induction:

\[
\begin{align*}
[0] := \bot & & [1]: = id & & [e+f]: = w_{(f)}(f)\cdot [e] + w_{(e)}(e)\cdot [f] \\
[a]: = a & & [l]: = l & & [e\cdot f]: = w_{(f)}(f)\cdot [e] \cdot w_{(e)}(e)\cdot [f] \\
[e^*] := [e]^* & & [\nu_a.e]: = \nu_a[e] & & (if \ a\in \frac{1}{2}(e)) \\
[(\pi)\ ]e := (\pi)[e] & & [\nu_a.e]: = \nu_a.w_a[e] & & (if \ a\notin \frac{1}{2}(e))
\end{align*}
\]

The notation \(w_A.e\) is justified by the law \(w_{a}w_{b}e = w_{b}w_{a}e\), holding in every typed theory.
Furthermore, if write as a relation is to consider memory states as functions, associating values to memory cells. A of expressions. As explained in the introduction, the classical way of interpreting a program for any expression \( e \), the expression \( a \) to the theory of these sets.

3.2.3 From atomic to literate

We assume there is an atom \( \alpha \in A \) and an element \( \lambda \in \mathcal{L} \) with \( \mathcal{I}(\lambda) = \{ \alpha \} \). We show the transformation from \( E^+(\mathcal{A}) \cap U \) to \( E^+(\mathcal{L}) \cap U \), which corresponds to the central horizontal top arrow on Figure 1. Let NKApu be the set of axioms \( (2a), (4a), (5b), (6b), (6e) \) corresponding to the theory of these sets.

**Definition 20** (From atoms to letters.). Given an expression \( e \in E^+(\mathcal{A}) \cap U \), we obtain the expression \( \{ e \} \in E^+(\mathcal{L}) \cap U \) by replacing every atomic variable \( a \) by \( \mathcal{I}(\lambda) \). We write \( \{ E^+(\mathcal{A}) \cap U \} \) for the set of expressions \( f \in E^+(\mathcal{L}) \cap U \), such that there is an expression \( e \in E^+(\mathcal{A}) \cap U \) such that \( f = \{ e \} \).

For any expression \( e \), \( e \in \{ E^+(\mathcal{A}) \cap U \} \) if and only if each literate variable in \( e \) has the identifier \( x \). It is also worth noting that \( | \_ \| \) preserves freshness: \( a \neq e \Rightarrow a \neq | e | \). As for typed and untyped expressions, we define an inverse operation.

**Definition 21** (Going back). The inverse operation is only defined on literate expressions whose variables carry the identifier \( x \), and thus have a singleton support. The expression \( \mathcal{I}(\_\_\) is then obtained by replacing every variable by the single atom in its support.

The function \( \mathcal{I}(\_\_\) is the inverse of \( \_\_\| \), \( \| \_\_ \) preserves NKApu-equality, and \( \| \_\_\) preserves NKApu-equality on the image of \( \| \_\_ \).

**Lemma 22.** \( \forall e \in E^+(\mathcal{A}) \cap U \), NKApu \( \mathcal{I}(e) = \mathcal{I}(\| e \|) \).

**Lemma 23.** \( \forall e, f \in E^+(\mathcal{A}) \cap U \), NKApu \( e = f \Rightarrow NKApu \mathcal{I}(e) = \mathcal{I}(f) \).

**Lemma 24.** \( \forall e, f \in E^+(\mathcal{L}) \cap U \cap \{ E^+(\mathcal{A}) \cap U \}, NKApu \mathcal{I}(e) = f \Rightarrow NKApu \mathcal{I}(\| e \|) = \mathcal{I}(f) \).

By putting all together, we obtain that \( \| \_\_ \) is an embedding of \( E^+(\mathcal{A}) \cap U \) into \( E^+(\mathcal{L}) \cap U \).

4 Relational interpretation of literate expressions

Our main motivation for developing the typed syntax was to define a relational interpretation of expressions. As explained in the introduction, the classical way of interpreting a program as a relation is to consider memory states as functions, associating values to memory cells. A
program is then simply a relation between memory states. Furthermore, in most high level
programming languages, one cannot access every part of the memory: a variable should be
declared before it is used. There are also constructs allowing one to declare a local variable,
which is hidden from the rest of the program. Both of these considerations can be encoded
by considering functions with a finite domain: the set of memory locations that are visible in
the current scope.

Let us be more precise. Consider that the set \( \mathcal{A} \) of atoms corresponds to memory locations,
and that locations may contain values from an arbitrary set \( \mathcal{V} \). A memory state of domain
\( A \in \mathcal{P}_f(\mathcal{A}) \) is then a function from \( A \) to \( \mathcal{V} \), and an expression of type \( A \) will be interpreted
as a binary relation over memory states of domain \( A \) (whence the presheaf structure).

Regular operations are interpreted using the standard operations on binary relations;
in particular, \( id_A \) is interpreted as the identity relation on \( \mathcal{V}^A \). To interpret letters, we
need to fix an equivariant map \( \phi \) that assign to a letter \( x \) a relation between memory states
with domain \( \mathcal{V}(x) \). Several choices are possible for the operations of restriction \( (\nu_a) \)
and weakening \( (w_a) \), yielding slightly different theories. Here is a possibility which gives rise to a
model of our theory: if \( R \) is a relation over \( \mathcal{V}^A \), then we define
\[
\nu_a.R := \{(f \upharpoonright_A, g \downharpoonright_A) \mid (f, g) \in R\} \quad \text{if } a \in A
\]
\[
w_a.R := \{(f, g) \mid (f \upharpoonright_A, f \downharpoonright_A) \in R \text{ and } f(a) = g(a)\} \quad \text{if } a \notin A
\]
(Where \( f \upharpoonright_A \) is the restriction of a function \( f \in \mathcal{V}^B \) for some superset \( B \) of \( A \).)

Note that this model is not free: for all relations \( R, S \) we have \( \nu_a.(R \cdot S) \subseteq (\nu_a.R) \cdot (\nu_a.S) \),
which is not an inequation provable from the axioms.

**Example.**

Consider the program \( \text{swap}(x, y) \) that exchanges the contents of the variables \( x \) and \( y \). The
natural implementation of this program is the following: \( \text{let } t \text{ in } t \leftarrow x; x \leftarrow y; y \leftarrow t \).

The instruction \( x \leftarrow y \) may be represented by a nominal element \( \text{assign}(x, y) \) with
support \( \{x, y\} \), and such that \( \pi(\text{assign}(x, y)) = \text{assign}(\pi(x), \pi(y)) \). Accordingly, the
program \( \text{swap} \) is represented by the following expression, where the location is hidden using
a top-level restriction.
\[
\nu_1.(\text{assign}(t, x) \cdot \text{assign}(x, y) \cdot \text{assign}(y, t)).
\]

Alternatively, one can obtain an expression with a single letter using explicit permutations:
let \( a_1 \) and \( a_2 \) be two atoms, and set \( a = \text{assign}(a_1, a_2) \). The instruction \( x \leftarrow y \) may be
represented by \( (((x a_1) (y a_2))a) \), and the program \( \text{swap} \) by
\[
\nu_1.(((t a_1) (x a_2))a) \cdot (((x a_1) (y a_2))a) \cdot (((a a_1) (t a_2))a).
\]

## 5 Future work

We leave two questions for future work. First, is it possible to reduce the literate theory of
nominal Kleene algebra to that of atomic nominal Kleene algebra? If not, is there a free
language theoretic model for which we could obtain decidability?

Second, is there a free relational model for our literate theory?

**Acknowledgements.**

We would like to thank Daniela Petrisan and Alexandra Silva for the discussions that have
led to this work.
