Keywords: Lojasiewicz-Simon inequality, gradient flow, Cahn-Hilliard, backward differentiation formula.

AMS Subject Classification: 65M10, 65P05, 37M.

Abstract

We consider a second-order two-step time semi-discretization of the Cahn-Hilliard equation with an analytic nonlinearity. The time-step is chosen small enough so that the pseudo-energy associated with the discretization is non-increasing at every time iteration. We prove that the sequence generated by the scheme converges to a steady state as time tends to infinity. We also obtain convergence rates in the energy norm. The proof is based on the Lojasiewicz-Simon inequality.

1 Introduction

In this paper, we consider a second-order time semi-discretization of the Cahn-Hilliard equation with an analytic nonlinearity, and we prove that any sequence generated by the scheme converges to a steady state as time goes to infinity, provided that the time-step is chosen small enough.

The Cahn-Hilliard equation \([10]\) reads

\[
\begin{cases}
  u_t = \Delta w \\
  w = -\gamma \Delta u + f(u)
\end{cases}
\]

in \(\Omega \times (0, +\infty)\),

(1.1)

where \(\Omega\) is a bounded subset of \(\mathbb{R}^d\) (1 \(\leq d \leq 3\)) with smooth boundary and \(\gamma > 0\). A typical choice for the nonlinearity is

\[f(s) = c(s^3 - s)\]

with \(c > 0\). More general conditions on \(f\) are given in Section 2, see (2.3)-(2.5).

Equation (1.1) is completed with Neumann boundary conditions and an initial data. The Cahn-Hilliard equation was analyzed by many authors and used in different contexts (see, e.g., \([11, 37]\) and references therein). In particular, it is a \(H^{-1}\) gradient flow for the energy

\[E(u) = \int_\Omega \frac{\gamma}{2} |\nabla u|^2 + F(u) \, dx,\]

where \(F\) is an antiderivative of \(f\). Convergence of single trajectories to equilibrium for (1.1)-(1.2) has been proved in \([42]\). The proof uses the gradient flow structure of the equation and a Lojasiewicz-Simon inequality \([44]\).

In one space dimension, the set of steady states corresponding to (1.1)-(1.2) is finite \([24, 32]\). In this case, the use of a Lojasiewicz-Simon inequality can be avoided \([51]\) but otherwise, the situation is highly complicated: if \(d = 2\) or 3, there may even be a continuum of stationary solutions (see, e.g., \([47]\) and references therein). The Lojasiewicz-Simon inequality allows to prove convergence to an equilibrium without any knowledge on the set of steady states. This celebrated inequality is based on the analyticity of \(f\) (see \([27]\) for a recent overview). In contrast, for the related semilinear parabolic equation, convergence to equilibrium may fail for a nonlinearity of class \(C^\infty\) \([39]\).

Using similar techniques, convergence to equilibrium for the non-autonomous Cahn-Hilliard equation was proved in \([15]\), and the case of a logarithmic nonlinearity was considered in \([1]\). The Cahn-Hilliard equation endowed with dynamic or Wentzell boundary conditions was analyzed in \([14, 40, 48, 49]\). Coupled systems were also considered (see, e.g., \([18, 30, 41]\]).

Since many space and/or time discretizations of the Cahn-Hilliard equation are available in the literature (see, e.g., \([5, 17, 20, 21, 22, 26, 36, 43, 50]\)), it is natural to ask whether convergence to equilibrium also holds for these discretizations, by using similar techniques.

If we consider only a space semi-discretization of (1.1), and if this discretization can be shown to preserve the gradient flow structure, then convergence to equilibrium is a consequence of Lojasiewicz’s classical convergence result \([33]\) and its generalizations \([8, 27]\). Thanks to the finite dimension, the Lojasiewicz-Simon inequality
reduces to the standard Lojasiewicz inequality. The latter is a direct consequence of analyticity of the discrete energy functional.

Thus, the situation regarding the space discretization is well understood, and we believe that the focus should be put on the time discretization, in the specific case where the time scheme preserves the gradient flow structure. In this regard, convergence to equilibrium for a fully discrete version of (1.1)-(1.2) was first proved in [34]: the time scheme was the backward Euler scheme and the space discretization was a finite element method. Fully discretized versions of Cahn-Hilliard type equations were considered in [12, 13, 29], where this nice feature of the backward Euler scheme was again demonstrated (see also [6, 25]). In [4], convergence to equilibrium was proved for several fully discretized versions of the closely related Allen-Cahn equation; the time scheme was either first order or second order, conditionnally or unconditionally stable, and the time-step could possibly be variable. In addition, general conditions ensuring convergence to equilibrium for a time discretization were given (see also [7]).

Therefore, the fully discrete case is now also well understood. The last stage is to study the time semi-discrete case. This is all the more interesting since this approach is independent of a choice of a specific space discretization. Convergence to equilibrium was proved for the backward Euler time semi-discretization of the Allen-Cahn equation in [34] (see also [9]). A related damped wave equation was considered in [38].

For schemes different from the backward Euler method, the situation is not so clear, and this is well illustrated by the second order case. Indeed, there exist several second-order time semi-discretizations of (1.1)-(1.2) which preserve the gradient flow structure (see, e.g., [43, 50] and references therein). Most of these schemes are one-step methods, which can be seen as variants of the Crank-Nicolson scheme, such as the classical secant scheme [16, 17] or the more recent scheme of Gomez and Hughes [21], which is a Crank-Nicolson scheme with stabilization.

However, we have not been able to prove convergence to equilibrium for any of these second-order one-step schemes. One difficulty is that the gradient of $E$ (cf. (3.2)) is treated in an implicit/explicit way, and another difficulty is that the discrete dynamical system associated with the scheme is defined on a space of infinite dimension. The first difficulty can be circumvented in finite dimension, as recently shown in [23], where convergence to equilibrium was proved for a fully discrete approximation of the modified phase-field crystal equation using the second-order time discretization of Gomez and Hughes. A related difficulty has been pointed out in [46] where the stability of the Crank-Nicolson scheme for the Navier-Stokes equation was proved in a finite dimensional setting only.

In this paper, instead of a Crank-Nicolson type method, we use a standard two-step scheme with fixed time-step, namely the backward differentiation formula of order two. It is well-known [43, 45] that this scheme enjoys a Lyapunov stability, namely, if the time-step is small enough, a so-called pseudo-energy (cf. (2.17)) is nonincreasing at every time iteration. Thanks to the implicit treatment of the gradient of $E$ (cf. (2.13)), the proof of convergence is similar to the case of the backward Euler scheme in [34, 38]. Using the Lyapunov stability, we first prove Lasalle’s in-
variance principle by a compactness argument (Proposition 3.1). Convergence to a steady state is then obtained as a consequence of an appropriate Lojasiewicz-Simon inequality (Lemma 3.2), which is the most technical point. In order to derive the convergence rate in $H^1$ norm, we also take advantage of the fact that the scheme is more dissipative than the original equation (see Remark 2.4).

It would be interesting to extend our convergence result to first-order or second-order schemes where the nonlinearity is treated explicitly. In order for such schemes to preserve the gradient structure, the standard approach is to truncate the cubic nonlinearity $f$ (cf. (1.2)) at $\pm \infty$ so as to have a linear growth at most $[43]$. However, it is not known if the energy associated with such a nonlinearity satisfies a Lojasiewicz-Simon inequality, in contrast with the finite-dimensional case where it can be proved for certain space discretizations [4].

It could also be of interest to investigate whether a similar convergence result holds for the $p$-step backward differentiation formula (BDF), with $p \geq 3$. A favorable situation is the 3-step BDF method, which preserves the gradient flow structure, at least in finite dimension [45].

The paper is organized as follows. In Section 2, we introduce the scheme, we establish its well-posedness and we show that it is Lyapunov stable. In Section 3, we prove the convergence result.

2 The time semi-discrete scheme

2.1 Notation and assumptions

Let $H = L^2(\Omega)$ be equipped with the $L^2(\Omega)$ norm $|\cdot|_0$ and the $L^2(\Omega)$ scalar product $(\cdot, \cdot)$. We denote $V = H^1(\Omega)$ the standard Sobolev space based on the $L^2(\Omega)$ space. We use the hilbertian semi-norm $|\cdot|_1 = |\nabla \cdot|_0$ in $V$, and the norm in $V$ is $\|v\|_1^2 = |v|^2_0 + |v|^2_1$. We denote $-\Delta : V \rightarrow V'$ the bounded operator associated with the inner product on $V$ through

$$\langle -\Delta u, v \rangle_{V', V} = (\nabla u, \nabla v), \quad \forall u, v \in V,$$

where $V'$ is the topological dual of $V$. As usual, we will denote $W^{k,p}(\Omega)$ the Sobolev spaces based on the $L^p(\Omega)$ space [19].

For a function $u \in L^2(\Omega)$, we denote

$$\langle u \rangle = \frac{1}{|\Omega|} \int_{\Omega} u \quad \text{and} \quad \dot{u} = u - \langle u \rangle,$$

where $|\Omega|$ is the Lebesgue measure of $\Omega$. We also define

$$\hat{H} = \{ u \in L^2(\Omega), \langle u \rangle = 0 \}, \quad \hat{V} = V \cap \hat{H}.$$

We will use the continuous and dense injections

$$\hat{V} \subset \hat{H} \subset \hat{H}' \subset \hat{V}'.$$

4
As a consequence of the Poincaré-Wirtinger inequality, the norms \( \|v\|_1 \) and
\[
\|v\|_1 = (|v|^2 + \langle v \rangle^2)^{1/2}
\]
are equivalent on \( V \). The operator \(-\Delta : \dot{V} \to \dot{V}'\), that is the restriction of \(-\Delta\), is an isomorphism. The scalar product in \( \dot{V}' \) is given by
\[
(\dot{u}, \dot{v})_{-1} = (\nabla(-\Delta)^{-1}\dot{u}, \nabla(-\Delta)^{-1}\dot{v}) = \langle \dot{u}, (-\Delta)^{-1}\dot{v} \rangle_{\dot{V}', \dot{V}}
\]
and the norm is given by
\[
|\dot{u}|_{-1}^2 = (\dot{u}, \dot{u})_{-1} = \langle \dot{u}, (-\Delta)^{-1}\dot{u} \rangle_{\dot{V}', \dot{V}}.
\]
We recall the interpolation inequality
\[
|\dot{u}|_{0}^2 \leq |\dot{u}|_{-1} |\dot{u}|_1, \quad \forall \dot{u} \in \dot{V}.
\]
We assume that the nonlinearity \( f : \mathbb{R} \to \mathbb{R} \) is analytic and if \( d \geq 2 \), we assume in addition that there exist a constant \( C > 0 \) and a real number \( p \geq 0 \) such that
\[
|f'(s)| \leq C(1 + |s|^p), \quad \forall s \in \mathbb{R},
\]
with \( p < 4 \) if \( d = 3 \). No growth assumption is needed if \( d = 1 \). We also assume that
\[
f'(s) \geq -c_f, \quad \forall s \in \mathbb{R},
\]
for some (optimal) nonnegative constant \( c_f \), and that
\[
\liminf_{|s| \to +\infty} \frac{f(s)}{s} > 0.
\]
We define the energy functional
\[
E(u) = \frac{\gamma}{2} |u|^2_1 + (F(u), 1),
\]
where \( F(s) \) is a given antiderivative of \( f \). The Sobolev injection \( V \subset L^{p+2}(\Omega) \) and the growth assumption (2.3) ensure that \( E(u) < +\infty \) and \( f(u) \in V' \), for all \( u \in V \). In fact, by [31, Corollaire 17.8], the functional \( E \) is of class \( C^2 \) on \( V \). For any \( u, v, w \in V \), we have
\[
\langle dE(u), v \rangle_{V', V} = \int_{\Omega} [\gamma \nabla u \cdot \nabla v + f(u)v] dx,
\]
\[
\langle d^2 E(u)v, w \rangle_{V', V} = \int_{\Omega} [\gamma \nabla v \cdot \nabla w + f'(u)vw] dx,
\]
where \( dE(u) \in V' \) is the first differential of \( E \) at \( u \) and \( d^2 E(u) \in \mathcal{L}(V, V') \) is the differential of order two of \( E \) at \( u \).

If \( u \) is a regular solution of (1.1), on computing we see that
\[
\frac{d}{dt} E(u(t)) = -|w|^2_1 - |w_t|_{-1}^2 \geq 0,
\]
so that \( E \) is a Lyapunov functional associated with (1.1).
2.2 Existence, uniqueness and Lyapunov stability

Let \( \tau > 0 \) denote the time-step. The second-order backward differentiation scheme for (1.1) reads [43, 45]: let \((u_0, u_1) \in V \times V \) and for \( n = 1, 2, \ldots \), let \((u_{n+1}, w_{n+1}) \in V \times V \) solve

\[
\begin{cases}
\frac{1}{2\tau}(3u_{n+1} - 4u_n + u_{n-1}, \varphi) + (\nabla w_{n+1}, \nabla \varphi) = 0 \\
(w_{n+1}, \psi) = \gamma(\nabla u_{n+1}, \nabla \psi) + (f(u_{n+1}), \psi),
\end{cases}
\]

(2.10)

for all \((\varphi, \psi) \in V \times V \). For simplicity, we assume that

\[
\langle u_0 \rangle = \langle u_1 \rangle,
\]

(2.11)

so that, by induction, any sequence \((u_n)\) which complies with (2.10) satisfies \(\langle u_n \rangle = \langle u_0 \rangle\) for all \( n \) (choose \( \varphi = 1/|\Omega| \) in (2.10)). We note that \( w_0 \) and \( w_1 \) need not be defined.

For later purpose, we note that if \(\langle u_n \rangle = \langle u_{n-1} \rangle\), then (2.10) is equivalent to

\[
\begin{cases}
\langle u_{n+1} \rangle = \langle u_n \rangle \\
(-\Delta)^{-1}\frac{(3u_{n+1} - 4u_n + u_{n-1})}{2\tau} + \dot{w}_{n+1} = 0 \\
\dot{w}_{n+1} = -\gamma \Delta u_{n+1} + f(u_{n+1}) - \langle f(u_{n+1}) \rangle \\
\langle w_{n+1} \rangle = \langle f(u_{n+1}) \rangle.
\end{cases}
\]

(2.12)

Eliminating \( w_{n+1} \) leads to

\[
(-\Delta)^{-1}\frac{(3u_{n+1} - 4u_n + u_{n-1})}{2\tau} - \gamma \Delta u_{n+1} + f(u_{n+1}) - \langle f(u_{n+1}) \rangle = 0.
\]

(2.13)

Proposition 2.1 (Existence for all \( \tau \)). For all \((u_0, u_1) \in V \times V \) such that \(\langle u_0 \rangle = \langle u_1 \rangle\), there exists at least one sequence \(\langle u_n, w_n \rangle_n\) which complies with (2.10). Moreover, \(\langle u_n \rangle = \langle u_0 \rangle\) for all \( n \).

Proof. Existence can be obtained by minimizing an appropriate functional. By induction, assume that for some \( n \geq 1 \), \((u_{n-1}, u_n) \in V \times V \) is defined, with \(\langle u_n \rangle = \langle u_{n-1} \rangle = \langle u_0 \rangle\). Then, by (2.13), \( u_{n+1} \) can be obtained by solving

\[
\min \{ \mathcal{G}_n(v) : v \in V, \langle v \rangle = \langle u_0 \rangle \},
\]

(2.14)

where

\[
\mathcal{G}_n(v) = \frac{3}{4\tau} \| \dot{\varphi} \|_{-1}^2 + \frac{1}{2\tau} (-4\dot{u}_n + \dot{u}_{n-1}, \dot{v})_{-1} + E(v).
\]

By (2.5), there exist \( \kappa_1 > 0 \) and \( \kappa_2 \geq 0 \) such that

\[
F(s) \geq \kappa_1 s^2 - \kappa_2, \quad \forall s \in \mathbb{R}.
\]

Thus, for all \( v \in V \),

\[
(F(v), 1) \geq \kappa_1 |v|^2 - \kappa_2 |\Omega|,
\]

6
and so
\[ E(v) \geq \kappa_3 \|v\|_1^2 - \kappa_2 |\Omega|, \]  
with \( \kappa_3 = \min\{\gamma/2, \kappa_1\} > 0 \). Moreover, by the Cauchy-Schwarz inequality,
\[ |(-4\dot{u}_n + \dot{u}_{n-1}, \dot{v})_{-1} | \leq |\dot{v}|_{-1} - 4\dot{u}_n + \dot{u}_{n-1}, | \leq \frac{3}{2} |\dot{v}|_{-1}^2 + C_n, \]
for some constant \( C_n \) which depends on \( |\dot{u}_n|_{-1} \) and \( |\dot{u}_{n-1}|_{-1} \). Summing up, we have proved that
\[ G_n(v) \geq \kappa_3 \|v\|_1^2 - \kappa_2 |\Omega| - \frac{C_n}{2\tau}. \]
By considering a minimizing sequence \((v_k)\) for problem (2.14), we obtain a minimizer, i.e. \( u_{n+1} \). Then \( w_{n+1} \) can be recovered from \( u_{n+1} \) by (2.12). \( \square \)

**Proposition 2.2** (Uniqueness). If \( 1/\tau > c_f^2/(6\gamma) \), then for every \((u_0, u_1) \in V \times V\) such that \( \langle u_0 \rangle = \langle u_1 \rangle \), there exists at most one sequence \((u_n, w_n)\) which complies with (2.10).

**Proof.** Assume that \((u_{n+1}, w_{n+1})\) and \((\tilde{u}_{n+1}, \tilde{w}_{n+1})\) are two solutions of (2.10), and denote \( \delta u = u_{n+1} - \tilde{u}_{n+1}, \delta w = w_{n+1} - \tilde{w}_{n+1} \). On subtracting, we obtain
\[ 
\begin{align*}
3(\delta u, \varphi)/(2\tau) + (\nabla \delta w, \nabla \varphi) &= 0, \\
(\delta w, \psi) &= \gamma(\nabla \delta u, \nabla \psi) + (f(u_{n+1}) - f(\tilde{u}_{n+1}), \psi),
\end{align*}
\]  
(2.16)
for all \((\varphi, \psi) \in V \times V\). Choosing \( \varphi = \delta w \) and \( \psi = \delta u \), yields
\[ -(2\tau/3)|\delta w|_1^2 = \gamma|\delta u|_1^2 + (f(u_{n+1}) - f(\tilde{u}_{n+1}), \delta u). \]
Using the mean value inequality and (2.4) yields
\[ (s - r)(f(s) - f(r)) = f'(\xi)(s - r)^2 \geq -c_f(s - r)^2, \]
for all \( r, s \in \mathbb{R} \), for some \( \xi \in \mathbb{R} \) depending on \( r, s \). Thus,
\[ c_f|\delta u|_0^2 \geq \gamma|\delta u|_1^2 + (2\tau/3)|\delta w|_1^2. \]
Using now (2.16) with \( \varphi = \delta u \), we obtain
\[ c_f|\delta u|_0^2 = -(2\tau c_f/3)(\nabla \delta w, \nabla \delta u) \leq \gamma|\nabla \delta u|_0^2 + \frac{\tau c_f^2}{9\gamma}|\nabla \delta w|_1^2. \]
If \( \tau c_f^2 < 6\gamma \), then \( \delta w = 0 \), and by (2.16), \( \delta u = 0 \) also. Uniqueness follows. \( \square \)

We define the following pseudo-energy
\[ E(u, v) = E(u) + \frac{1}{4\tau}|\dot{v}|_{-1}^2, \quad \forall (u, v) \in V \times V'. \]  
(2.17)
For a sequence \((u_n)\), let also \( \delta u_n = u_n - u_{n-1} \) denote the backard difference. The following relation will prove useful,
\[ 3u_{n+1} - 4u_n + u_{n-1} = 2\delta u_{n+1} + (\delta u_{n+1} - \delta u_n). \]  
(2.18)
Next, we use the well-known identity
\[
E(u_{n+1}, \delta u_{n+1}) + \frac{\varepsilon \gamma}{2} |u_{n+1} - u_n|^2 + \left( \frac{1}{\tau} - \frac{c_f^2}{8\gamma(1-\varepsilon)} \right) |u_{n+1} - u_n|^2
\]
\[+ \frac{1}{4\tau} |\delta u_{n+1} - \delta u_n|^2 \leq E(u_n, \delta u_n).
\] (2.19)

**Proof.** We take the \(L^2\) scalar product of equation (2.13) by \(\delta u_{n+1}\) and we use (2.18). We obtain
\[
\frac{1}{\tau} |\delta u_{n+1}|^2 + \frac{1}{2\tau} (\delta u_{n+1} - \delta u_n, \delta u_{n+1}) - \gamma (\nabla u_{n+1}, \nabla (u_{n+1} - u_n)) = (f(u_{n+1}), u_n - u_{n+1}).
\]
By the Taylor-Lagrange formula, from (2.4), we deduce that
\[
F(r) - F(s) \geq f(s)(r - s) - \frac{c_f}{2} |r - s|^2, \quad \forall r, s \in \mathbb{R}.
\]
Thus,
\[
(f(u_{n+1}), u_n - u_{n+1}) \leq (F(u_n), 1) - (F(u_{n+1}), 1) + \frac{c_f}{2} |u_{n+1} - u_n|^2.
\]
Next, we use the well-known identity
\[
(a, a - b)_m = \frac{1}{2} |a|_m^2 - \frac{1}{2} |b|_m^2 + \frac{1}{2} |a - b|_m^2,
\]
for \(m = -1\) and \(m = 0\). We find
\[
\frac{1}{\tau} |\delta u_{n+1}|^2 + \frac{1}{4\tau} (|\delta u_{n+1}|^2 - |\delta u_n|^2 + |\delta u_{n+1} - \delta u_n|^2)
\]
\[+ \frac{\gamma}{2} (|u_{n+1}|^2 - |u_n|^2 + |u_{n+1} - u_n|^2)
\]
\[\leq (F(u_n), 1) - (F(u_{n+1}), 1) + \frac{c_f}{2} |u_{n+1} - u_n|^2.
\] (2.20)
The interpolation inequality (2.2) and Young’s inequality yield
\[
\frac{c_f}{2} |u_{n+1} - u_n|^2 \leq \frac{\gamma (1 - \varepsilon)}{2} |u_{n+1} - u_n|^2 + \frac{c_f^2}{8\gamma(1-\varepsilon)} |u_{n+1} - u_n|^2.
\]
Plugging this into (2.20) gives (2.19).

**Remark 2.4.** If \(\tau\) is small enough, then by choosing \(\varepsilon \in (0, 1)\), we see that the scheme (2.10) is more dissipative than the original equation (1.1), since the \(H^1\) norm \(|u_{n+1} - u_n|^2\) appears in (2.19); in contrast, only the \(H^{-1}\) norm \(|u_t|^2\) appears in (2.9).
3 Convergence to equilibrium

For a sequence \((u_n)_n \) in \(V \), we define its omega-limit set by
\[
\omega((u_n)_n) := \{ u_* \in V : \exists n_k \to \infty, u_{n_k} \to u_* \text{ (strongly) in } V \}.
\]

Let \( M \in \mathbb{R} \) be given and consider the following affine subspace of \( V \),
\[
V_M = \{ v \in V : \langle v \rangle = M \} = M + \dot{V}.
\]  
(3.1)

The set of critical points of \( E \) (see (2.6)) in \( V_M \) is
\[
\mathcal{S}_M = \{ u^* \in V_M : -\gamma \Delta u^* + f(u^*) - \langle f(u^*) \rangle = 0 \text{ in } \dot{V}' \}.
\]

Indeed, we already know that \( E \in C^2(V_M; \mathbb{R}) \). Observe that, for any \( u \in V_M, \dot{v} \in \dot{V} \), we have (see (2.7))
\[
\langle dE(u), v \rangle_{\dot{V}, \dot{V}} = \int_{\Omega} [\gamma \nabla u \cdot \nabla v + f(u)v] dx
\]
\[
= \int_{\Omega} [\gamma \nabla u \cdot \nabla v + (f(u) - \langle f(u) \rangle)v] dx
\]
\[
= \langle -\gamma \Delta u + f(u) - \langle f(u) \rangle, v \rangle_{\dot{V}, \dot{V}}.
\]  
(3.2)

By definition, \( u^* \) is a critical point of \( E \) in \( V_M \) if \( dE(u^*) = 0 \) in \( \dot{V}' \). The definition of \( \mathcal{S}_M \) follows.

**Proposition 3.1.** Assume that \( 1/\tau > c_f^2/(8\gamma) \) and let \((u_n, w_n)_n \) be a sequence which complies with (2.10)-(2.11). Then \( \delta u_n \to 0 \) in \( V \) and \( \omega((u_n)_n) \) is a nonempty compact and connected subset of \( V \) which is included in \( \mathcal{S}_M \) with \( M = \langle u_0 \rangle \). Moreover, \( E \) is constant on \( \omega((u_n)_n) \).

**Proof.** Using the assumption on \( \tau \), we may choose \( \varepsilon \in (0,1) \) such that \( 1/\tau = c_f^2/(8\gamma(1-\varepsilon)) \). Then (2.19) reads
\[
\mathcal{E}(u_{n+1}, \delta u_{n+1}) + \frac{\varepsilon \gamma}{2} |u_{n+1} - u_n|^2 + \frac{1}{4\tau} |\delta u_{n+1} - \delta u_n|^2_{-1} - \mathcal{E}(u_n, \delta u_n),
\]  
(3.3)

for all \( n \geq 1 \). In particular, \((\mathcal{E}(u_n, \delta u_n))_n \) is non increasing. Moreover, by (2.15),
\[
\mathcal{E}(u, v) \geq \kappa_3 ||u||_1^2 + \frac{1}{4\tau} ||v||_{-1}^2 - \kappa_2 |\Omega|, \quad \forall (u,v) \in V \times V'.
\]  
(3.4)

Since \( \mathcal{E}(u_1, \delta u_1) < +\infty \), we deduce from (3.4) that \((u_n, \delta u_n) \) is bounded in \( V \times V' \) and that \( \mathcal{E}(u_n, \delta u_n) \) is bounded from below. Thus, \( \mathcal{E}(u_n, \delta u_n) \) converges to some \( \mathcal{E}_* \) in \( \mathbb{R} \). By induction, from (3.3)-(3.4) we also deduce that
\[
\sum_{n=1}^{\infty} |u_{n+1} - u_n|^2_1 \leq \frac{2}{\varepsilon \gamma} (\mathcal{E}(u_1, \delta u_1) + \kappa_2 |\Omega|) < +\infty.
\]

In particular, \( \delta u_n \to 0 \) in \( V \). This implies that \( E(u_n) \to \mathcal{E}_* \), and so \( E \) is equal to \( \mathcal{E}_* \) on \( \omega((u_n)_n) \).
Next, we claim that the sequence \((u_n)\) is precompact in \(V\). Let us first assume \(d = 3\). We deduce from the Sobolev imbedding [19] that \((u_n)\) is bounded in \(L^q(\Omega)\). By the growth condition (2.3), there exists \(2 \geq q > 6/5\) such that \(\|f(u_{n+1})\|_{L^q(\Omega)} \leq M_1\), where \(M_1\) is independent of \(n\). By elliptic regularity [3], we deduce from (2.13) that \((u_{n+1})_{n \geq 1}\) is bounded in \(W^{2,q}(\Omega)\). Finally, from the Sobolev imbedding [19], \(W^{2,q}(\Omega)\) is compactly imbedded in \(V\), and the claim is proved.

In the case \(d = 1\) or \(2\), we obtain directly from the Sobolev imbedding that \(f(u_{n+1})\) is bounded in \(L^q(\Omega)\), for any \(q < +\infty\), and we conclude similarly.

As a consequence, \(\omega((u_n)_n)\) is a nonempty compact subset of \(V\). Since \(|u_{n+1} - u_n|_1 \to 0\), \(\omega((u_n)_n)\) is also connected. Let finally \(u_*\) belong to \(\omega((u_n)_n)\), with \(n_k \to \infty\) such that \(u_{n_k} \to u_*\) in \(V\). We let \(n_k\) tend to \(\infty\) in (2.13). Thanks to (2.11), the whole sequence \((u_n)\) belongs to \(V_M\) and \(u_*\) as well, where \(M = \langle u_0\rangle\). By (2.18), the term corresponding to the discrete time derivative tends to \(0\) in \(V\), and we obtain that \(u_*\) belongs to \(\mathcal{S}_M\).

If the critical points of \(E\) are isolated, i.e. \(\mathcal{S}_M\) is discrete, then Proposition 3.1 ensures that the sequence \((u_n)_n\) converges in \(V\). However, as pointed out in the introduction, the structure of \(\mathcal{S}_M\) is generally not known, and there may even be a continuum of steady states. In such cases, the Lojasiewicz-Simon inequality which follows is needed to ensure convergence of the whole sequence \((u_n)\).

**Lemma 3.2.** Let \(u^* \in \mathcal{S}_M\). Then there exist constants \(\theta \in (0, 1/2)\) and \(\delta > 0\) depending on \(u^*\) such that, for any \(u \in V_M\) satisfying \(|u - u^*|_1 < \delta\), there holds

\[
|E(u) - E(u^*)|^{1-\theta} \leq | - \gamma \Delta u + f(u) - \langle f(u) \rangle|_{-1}. \tag{3.5}
\]

**Proof.** We will apply the abstract result of Theorem 11.2.7 in [27]. We introduce the auxiliary functional \(E_M(v) = E(M + v)\) on \(\hat{V}\). We will also use the auxiliary functions

\[
f_M(s) = f(M + s) \quad \text{and} \quad F_M(s) = F(M + s).
\]

It is obvious that

\[
E_M(v) = \int_\Omega \frac{\gamma}{2} |\nabla v|^2 + F_M(v) \, dx.
\]

The function \(E_M\) is of class \(C^2\) on \(\hat{V}\) and by (3.2), for any \(v \in \hat{V}\), we have

\[
dE_M(v) = -\gamma \Delta v + f_M(v) - \langle f_M(v) \rangle \text{ in } \hat{V}'.
\]

Similarly, by (2.8), for any \(v, \varphi \in \hat{V}\), we have

\[
d^2E_M(v)\varphi = -\gamma \Delta \varphi + f_M'(v)\varphi - \langle f_M'(v)\varphi \rangle \text{ in } \hat{V}'.
\tag{3.6}
\]

Let \(v^* \in \hat{V}\) be a critical point of \(E_M\), i.e. a solution of \(dE_M(v^*) = 0\) in \(\hat{V}'\). Using (2.3) and elliptic regularity, we obtain that \(v^* \in C^0(\Omega) \subset L^\infty(\Omega)\). In particular, \(f'_M(v^*) \in L^\infty(\Omega)\). The operator \(A = d^2E_M(v^*) \in \mathcal{L}(\hat{V}, \hat{V}')\) (cf. (3.6)) can be written

\[
A = -\gamma \Delta + P_0(f'_M(v^*)Id),
\]

where \(-\gamma \Delta : \hat{V} \to \hat{V}'\) is an isomorphism, \(P_0 : H \to \hat{H}\) is the \(L^2\)-projection operator, and \(f'_M(v^*)Id : \hat{V} \to \hat{H}\) is a multiplication operator. Since \(\hat{V}\) is compactly imbedded
in $\dot{H}$ [19], $f_M^∗(v^*)Id : \dot{V} \rightarrow H$ is compact, and $P_0(f_M^∗(v^*)Id)$ as well. Using [27, Theorem 2.2.5], we obtain that $A$ is a semi-Fredholm operator.

Next, let $N(A)$ denote the kernel of $A$, and $\Pi : \dot{V} \rightarrow N(A)$ the $L^2$ projection. By [27, Corollary 2.2.6], $L := A + \Pi : V \rightarrow V$ is an isomorphism. We choose $Z = H$ and denote $W = L^{-1}(Z)$; $W$ is a Banach space for the norm $\|w\| = |L(w)|_0$. We claim that $W$ is continuously imbedded in $W^{2,2}(\Omega)$. Indeed, by definition, $w \in W$ if and only if $w \in \dot{V}$ and $L(w) = g$ for some $g \in Z$, i.e.

$$w \in \dot{V} \text{ and } -\gamma \Delta w + f_M^∗(v^*)w - \langle f_M^∗(v^*)w \rangle + \Pi w = g.$$

Thus, $-\Delta w \in \dot{H}$. By elliptic regularity [3], $w \in W^{2,2}(\Omega)$. Moreover, by the triangle inequality,

$$\gamma | - \Delta w|_0 \leq C\|f_M^∗(v^*)\|\|L\|_0 + |\Pi w|_0 + |L(w)|_0 \leq C\|w\|\|w\|,$$

where $C$ is a constant independent of $w$. But, by elliptic regularity [3], we also know that $\|w\|_{W^{2,2}} \leq C | - \Delta w|_0$ for all $w \in \dot{V}$. This proves the claim.

The Nemytskii operator $f_M : v \mapsto f_M(v)$ is analytic from $L^\infty(\Omega)$ into $L^\infty(\Omega)$ (see [27, Example 2.3]). Using [27, Proposition 2.3.4], we find that the functional $v \mapsto \int_\Omega F_M(v)$ is real analytic from $L^\infty(\Omega)$ into $\mathbb{R}$. Thus, $E_M$, which is the sum of a continuous quadratic functional and of a functional which is real analytic on $W \subset W^{2,2}\Omega \subset L^\infty(\Omega)$, is real analytic on $W$. We also obtain that $dE_M : W \rightarrow Z$ is real analytic.

We are therefore in position to apply the abstract Theorem 11.2.7 in [27], which shows that there exist $\theta \in (0, 1/2)$ and $\delta > 0$ such that for all $v \in \dot{V}$,

$$|v - v^*|_1 < \delta \Rightarrow |E_M(v) - E_M(v^*)|^{1-\theta} \leq |dE_M(v)|_1.$$

Finally, we note that any $u^* \in S_M$ can be written $u^* = M + v^*$, where $v^*$ is a critical point of $E_M$; by definition of $V_M$, any $u \in V_M$ can be written $u = M + v$ with $v \in \dot{V}$. The expected Łojasiewicz-Simon inequality (3.5) is exactly (3.7) written in terms of $u^*$, $u$, $E$ and $f$. \hfill $\square$

**Theorem 3.3.** Assume that $1/\tau > c_1^2/(8\gamma)$ and let $(u_n, w_n)_1$ be a sequence which complies with (2.10)-(2.11). Then the whole sequence converges to $(u_\infty, w_\infty)$ in $V \times V$, with $u_\infty \in S_M$, $M = \langle u_0 \rangle$, and $w_\infty$ constant. Moreover, the following convergence rate holds

$$\|u_n - u_\infty\|_1 + \|w_n - w_\infty\|_1 \leq Cn^{-\frac{\theta}{\gamma - \tau}},$$

for all $n \geq 2$, where $C$ is a constant depending on $\|u_0\|_1$, $\|u_1\|_1$, $f$, $\gamma$, $\tau$, and $\theta$, while $\theta \in (0, 1/2)$ may depend on $u_\infty$.

**Proof.** Let $M = \langle u_0 \rangle$. For every $u_n \in \omega((u_n)_n)$, there exist $\theta \in (0, 1)$ and $\delta > 0$ which may depend on $u_n$ such that the inequality (3.5) holds for every $u \in B_\delta(u_n) = \{u \in V_M : |u - u_n| < \delta \}$. The union of balls $\{B_\delta(u_n) : u_n \in \omega((u_n)_n)\}$ forms an open covering of $\omega((u_n)_n)$ in $V_M$. Due to the compactness of $\omega((u_n)_n)$ in $V$, we can find a finite subcovering $\{B_\delta(u^*_i)\}_{i=1}^m$ such that the constants $\delta^i$ and $\theta^i$ corresponding to $u^*_i$ in Lemma 3.2 are indexed by $i$. \hfill 11
From the definition of $w((u_n)_n)$, we know that there exists a sufficiently large $n_0$ such that $u_n \in \mathcal{U} = \bigcup_{i=1}^m B_{\theta}(u^*_i)$ for all $n \geq n_0$. Taking $\theta = \min_{i=1}^m \{\theta^i\}$, we deduce from Lemma 3.2 and Proposition 3.1 that for all $n \geq n_0$,

$$|E(u_n) - \mathcal{E}_*|^{1-\theta} \leq | - \gamma \Delta u_n + f(u_n) - \langle f(u_n) \rangle|_{-1},$$

(3.9)

where $\mathcal{E}_*$ is the value of $E$ on $\omega((u_n)_n)$. We may also assume (by taking a larger $n_0$ if necessary) that for all $n \geq n_0$, $|\delta u_n|_{-1} \leq 1$.

We denote $\Phi_n = \mathcal{E}(u_n, \delta u_n) - \mathcal{E}_*$, so that $\Phi_n \geq 0$ and $\Phi_n$ is nonincreasing. Let $n \geq n_0$. Using the inequality $(a+b)^{1-\theta} \leq a^{1-\theta} + b^{1-\theta}$, valid for all $a, b \geq 0$, together with (3.9), we obtain

$$\Phi^{1-\theta}_{n+1} \leq |E(u_{n+1}) - \mathcal{E}_*|^{1-\theta} + (4\tau)^{\theta-1} |\delta u_{n+1}|^2_{-1}$$

$$\leq | - \gamma \Delta u_{n+1} + f(u_{n+1}) - \langle f(u_{n+1}) \rangle|_{-1} + (4\tau)^{\theta-1} |\delta u_{n+1}|_{-1}$$

$$\leq C (|u_{n+1} - u_n|_{-1} + |\delta u_{n+1} - \delta u_n|_{-1})$$

$$\leq C (|u_{n+1} - u_n|_1^2 + |\delta u_{n+1} - \delta u_n|_{-1}^2)^{1/2}$$

(3.10)

where $C = C(\tau, \gamma, \varepsilon) > 0$.

We may also assume (by taking a larger $n_0$ if necessary) that for all $n \geq n_0$, $|\delta u_n|_{-1} \leq 1$. Using (2.13) and (2.18). Next, we choose $\varepsilon \in (0,1)$ such that $1/\tau = c^2_f/(8\gamma(1 - \varepsilon))$. Then (3.3) holds, and it can be written

$$\Phi_n - \Phi_{n+1} \geq C (|u_{n+1} - u_n|_1^2 + |\delta u_{n+1} - \delta u_n|_{-1}^2),$$

(3.11)

with $C = C(\tau, \gamma, \varepsilon) > 0$.

Assume first that $\Phi_{n+1} > \Phi_n/2$. Then

$$\Phi^{\theta}_{n+1} - \Phi^{\theta}_n = \theta \int_{\Phi_n}^{\Phi_{n+1}} x^{\theta-1} dx \geq \theta \frac{\Phi_n - \Phi_{n+1}}{\Phi_n} \geq 2^{\theta-1} \theta \frac{\Phi_n - \Phi_{n+1}}{\Phi_{n+1}}.$$
for all $n \geq n_0$. Summing on $n \geq n_0$, we obtain

$$\sum_{n=n_0}^{\infty} |u_{n+1} - u_n| \leq C\Phi_{n_0}^{\theta} + C\Phi_{n_0}^{1/2} < +\infty. \quad (3.13)$$

Using the Cauchy criterion, we find that the whole sequence $(u_n)$ converges to some $u_\infty$ in $V$. By Proposition 3.1, $u_\infty$ belongs to $\mathcal{S}_M$. Using the second equation in (2.12), we see that $\dot{w}_n \to 0$. For the term $\langle w_n \rangle$, we write

$$\int_{\Omega} |f(u_n) - f(u_\infty)| \, dx = \int_{\Omega} \left| \int_{0}^{1} f'(s) u_n + s u_\infty \, ds \right| \, dx.$$

Using assumption (2.3), Hölder's inequality and Sobolev imbeddings, we find $Cn$ above. If $\Phi_n$ for all $n$, we see that $\dot{w}_n \to 0$. For all $n\geq n_0$, we may assume that $\Phi_n \to 0$. So we see that $\dot{\bar{u}}_n \to 0$. For the term $\langle w_n \rangle$, we write

$$\int_{\Omega} |f(u_n) - f(u_\infty)| \, dx \leq C\|u_n\|_1 \|u_\infty\|_1 \|u_n - u_\infty\|_1.$$

Since $(u_n)$ is bounded in $V$, this yields, for all $n \geq 2$,

$$|\langle w_n - w_\infty \rangle| = |\langle f(u_n) - f(u_\infty) \rangle| \leq (\|f(u_n) - f(u_\infty)\|) \leq C\|u_n - u_\infty\|_1, \quad (3.14)$$

where we have used the last equation in (2.12) and where $w_\infty = \langle f(u_\infty) \rangle$. This implies that $w_n \to w_\infty$ in $V$ (see (2.1)), and it concludes the proof of convergence.

For the convergence rate, we will first show that

$$0 \leq \Phi_n \leq C n^{-\frac{1}{1-2\theta}}, \quad (3.15)$$

for all $n \geq n_1$, for some $n_1 > n_0$ large enough. The exponent $\theta$ is the same as above. If $\Phi_{n_1} = 0$ for some $n_1 \geq n_0$, then $\Phi_n = 0$ for all $n \geq n_1$, and estimate (3.15) is obvious. So we may assume that $\Phi_n > 0$ for all $n$. Let $n \geq n_0$ and denote $G(s) = \frac{1}{s^{1-2\theta}}$. The sequence $G(\Phi_n)$ is nondecreasing and tends to $+\infty$.

If $\Phi_{n+1} > \Phi_n/2$, then

$$G(\Phi_{n+1}) - G(\Phi_n) = \int_{\Phi_{n+1}}^{\Phi_n} \frac{1 - 2\theta}{s^{2-2\theta}} \, ds$$

$$\geq (1 - 2\theta)2^{2\theta-2}\Phi_{n+1}^{2\theta-2}[\Phi_n - \Phi_{n+1}]$$

$$\geq C_1 \Phi_{n+1}^{2\theta-2}(\|u_{n+1} - u_n\|_1^2 + |\delta u_{n+1} - \delta u_n|_1^2)$$

$$\geq C_1,$$

where $C_1$ is a positive constant independent of $n$.

If $\Phi_{n+1} \leq \Phi_n/2$ and $\Phi_n \leq 1$, then

$$G(\Phi_{n+1}) - G(\Phi_n) \geq \frac{2^{1-2\theta} - 1}{\Phi_{n}^{1-2\theta}} \geq 2^{1-2\theta} - 1.$$

Let $n'_0 \geq n_0$ be large enough so that $\Phi_n' \leq 1$. Then, in both cases, for all $n \geq n'_0$, we have

$$G(\Phi_{n+1}) - G(\Phi_n) \geq C_2,$$
where $C_2 = \min\{C_1, 2^{1-2\theta} - 1\} > 0$. By summation on $n$, we obtain

$$G(\Phi_n) - G(\Phi_{n_0}) \geq C_2(n - n_0'),$$

for all $n \geq n_0'$. Thus, by choosing $n_1 > n_0'$ large enough, we have

$$G(\Phi_n) \geq \frac{C_2}{2}n,$$

for all $n \geq n_1$, which yields (3.15).

Now, by summing estimate (3.12) on $n$, we find

$$|u_n - u_\infty|_1 \leq \sum_{k=n}^\infty |u_{k+1} - u_k|_1 \leq C\Phi^{\theta}_n + C\Phi^{1/2}_n \leq C\Phi^{\theta}_n,$$

for all $n \geq n_1$. Using (3.15) yields

$$\|u_n - u_\infty\|_1 \leq Cn^{-\frac{\theta}{1-2\theta}}, \quad (3.16)$$

for all $n \geq n_1$. We may change the constant $C$ in order for the estimate to hold for all $n \geq 2$. From (3.16) and the second equation in (2.12), we obtain the convergence rate for $(\dot{w}_n)$. The convergence rate for $\langle w_n \rangle$ is a consequence of (3.16) and (3.14).

This concludes the proof. \[\square\]

**Remark 3.4.** It is possible to show that a local minimizer of $E$ in $V_M$ is stable uniformly with respect to $\tau$. More precisely, let $(u^\tau_n)_n$ denote a sequence which complies with (2.13) and corresponding to a time-step $\tau$. We assume $\tau \in (0, \tau^*)$ where $\tau^* > 0$ is such that $1/\tau^* > c^2/(8\gamma)$. If $u^* \in V_M$ is a local minimizer of $E$ in $V_M$, and if $u^\tau_0 = u^\tau_1$ is close enough to $u^*$ in $V_M$, then the whole sequence $(u^\tau_n)_n$ remains close to $u^*$, uniformly with respect to $\tau \in (0, \tau^*)$. The proof of this stability result is based on the Lojasiewicz-Simon inequality (it may be false for a $C^\infty$ nonlinearity, see [2]). It is proved in [4] for several fully discrete approximations of the Allen-Cahn equation. The case of the semi-discrete scheme (2.13) is more involved. Indeed, dissipative estimates (uniform in $\tau$) are needed to obtain pre-compactness of the set $\{u^\tau_n : \tau \in (0, \tau^*), n \in \mathbb{N}\}$ in $V_M$. Moreover, as $\tau \to 0^+$, the dissipation due to the scheme vanishes (cf. Remark 2.4). Thus, instead of the series $\sum_n |u^\tau_{n+1} - u^\tau_n|_1$ (cf. (3.13)), we have to deal with the series $\sum_n |u^\tau_{n+1} - u^\tau_n|_{-1}$. We refer the interested reader to [28, 35] for the proof of stability of a local minimizer in an infinite dimensional setting (for continuous dynamical systems).
