Bio-Based Aliphatic Polyurethanes Through ADMET Polymerization in Bulk and Green Solvent

Thomas Lebarbé, Arvind Sudhakar More, Prakash Sudhir Sane, Etienne Grau, Carine Alfos, Henri Cramail

Abstract

A new route to α,ω -diene urethane monomer is proposed by converting 10-undecenoic acid into the corresponding acyl azide, followed by urethanization with 10-undecenol. ADMET polymerizations of this α,ω -diene urethane monomer as well as other bio-based α,ω -dienes bearing various organic functions (ester, carbonate, ether, amide) were carried out in bulk and solution conditions. A screening of the most commonly used metathesis catalysts allows to evaluate their tolerance toward the urethane function as well as toward Polarclean, a “green” and nontoxic high boiling point solvent. The influence of the nature of the central organic function in these α,ω -diene monomers on the thermomechanical properties is investigated.

1 Introduction

Polyurethanes are among the most important polymeric materials with about 6% of the world plastic use.¹ In the last decade, many attempts have been carried out to develop greener routes to renewable polyurethanes. More particularly vegetable oils have gained high importance in that field due to their availability, sustainability, and their relatively low cost. A lot of investigations were carried out to design new aliphatic polyols for the traditional synthesis of polyurethanes networks and thermoplastics.²⁻⁴ Despite the low toxicity and the renewable character of these new bio-based polyols, diisocyanate synthesis still remains an issue regarding the commonly use of phosgene as carbonation agent and the toxicity of isocyanates.

In our effort to propose various pathways for polyurethane synthesis,⁵⁻⁷ we recently investigated acyclic diene metathesis (ADMET) polymerization for designing new bio-based aliphatic polyurethanes. Indeed, the emergence of highly tolerant metathesis catalysts in the 1990s enabled the use of functional monomers and afforded new pathways to various polymeric systems.^{8, 9} ADMET polymerization was already reported for the synthesis of fatty acid-based polyesters, polyamides, polyethers, and polycarbonates¹⁰⁻¹⁴ but, to the best of our knowledge, not for bio-based polyurethanes.

Here, we used 10-undecenoic acid platform as it is obtained by a two-step process from castor oil, a readily available annual plant seed oil.¹⁵ In continuation to recent investigations, we performed concerning AB-type self-condensation of hydroxyacyl azide,^{5, 7} and due to the efficiency and simplicity of the acyl-azide route for the formation of masked isocyanate, this approach was retained for the synthesis of α,ω -diene urethane.

2 Results and Discussion

2.1 Synthesis of the Novel Urethane Monomer

Prior to polymerizations study, a two-step methodology was applied for the synthesis of the urethane monomer (Figure 1). First, 10-undecenoic acid was reacted with ethyl chloroformate in the presence of triethylamine to

form in situ anhydride, which then reacted with sodium azide to obtain the acyl-azide compound. Completion of the reaction was monitored by FTIR-ATR (Figure S1, Supporting Information). The spectrum revealed the appearance of bands at 1720, 2120, and 2300 cm^{-1} , which are attributed to acyl azide C=O stretching, N_3 bending, and isocyanate N=C=O stretching modes. This analysis shows that a small fraction of the acyl-azide intermediate rearranged into the isocyanate compound (26%) by a Curtius rearrangement. It was also confirmed by ^1H NMR spectroscopy with the appearance of a signal at 3.28 ppm related to protons near the isocyanate group (Figure 2). However, the presence of isocyanate functions is not an issue as the latter will be also converted in the second step to the expected urethane.

Figure 1 Structure of the monomers and the catalysts used in this study.

Figure 2 ^1H NMR stacked spectra in CDCl_3 of the molecules at different steps of the synthesis of polyurethane and poly(ester-urethane).

The α,ω -diene urethane monomer (**1**) was then obtained by Curtius rearrangement with 10-undecenol. Its structure was confirmed by FTIR-ATR analysis (Figure S1, Supporting Information) as well as NMR spectroscopy (Figure 2; Figure S2–S4, Supporting Information). FTIR spectrum of (**1**) displays one band at 1700 cm^{-1} related to the C=O stretching of urethane function and a broad band at 3300 cm^{-1} related to NH bending. Regarding ^1H NMR spectrum of (**1**), neither acyl azide nor isocyanate has been observed after purification. New peaks appeared at 3.08, 3.97, and 4.54 ppm that are assigned, respectively, to the protons in α position of the urethane linkage as well as to the proton attached to the nitrogen atom.

2.2 Tolerance Investigation of the Catalysts Toward Polarclean Solvent

(**1**) was subjected to ADMET polymerization. ADMET is generally conducted in bulk when the melting points of both monomers and polymers are not too high ($<100\text{ }^\circ\text{C}$). In the case of ADMET in solution, a high boiling point solvent is generally needed to fit with the reaction conditions (temperature around $80\text{ }^\circ\text{C}$ with dynamic vacuum to eliminate the ethylene condensate). Solvents such as *o*-xylene or DMF fulfill the ADMET requirements, while their relative toxicity limit their use. Methyl-5-(dimethylamido)-2-methyl-5-oxopentanoate (Polarclean) is an eco-friendly water-soluble and polar solvent, which presents a high boiling point and a lower toxicity than *o*-xylene or DMF.¹⁶ Moreover, this solvent can be easily removed from the reaction mixture by washing with methanol or water.

To our knowledge, Polarclean was never employed in metathesis reactions. The first step was thus to evaluate the tolerance of frequently used ruthenium-based metathesis catalysts toward Polarclean. To that aim, a previously reported α,ω -diene ester monomer (**2**)¹¹ was synthesized (see Figures S5 and S6, Supporting Information) and used as a model in ADMET polymerizations.

(**2**) was first reacted in bulk with Grubbs 1st (**C1**), Grubbs 2nd (**C2**), Hoveyda–Grubbs 1st (**C3**), and Hoveyda–Grubbs 2nd (**C4**) generation catalysts. In all cases, the monomer feed was reacted with 0.5 mol% of catalyst at $80\text{ }^\circ\text{C}$ for 24 h under dynamic vacuum. When **C2** and **C4** were used, 5 mol% of *p*-benzoquinone was added to limit isomerization.^{17, 18} As expected, for all the reactions launched in bulk, good molecular weights were obtained, suggesting good tolerance of the catalysts toward the ester monomer (Table 1, entries 5^a–8^a). Interestingly, despite their lower reactivity in comparison to 2nd generation catalysts, 1st generation catalysts led to higher molecular weights. It was ascribed to limited isomerization with these catalysts. Isomerization lowers the degree of polymerization due to less-volatile side products than ethylene gas, which cannot be removed from the reaction mixture.

Table 1. Macromolecular characteristics of the polymers obtained by SEC in THF-PS calibration

Entry	Monomer	Catalyst	Mn [g mol ⁻¹] (Dispersity)	
			Bulk(a)	Polarclean(b)
1	1	C1	17 100 (1.7)	–
2		C2	9 300 (1.6)	–
3		C3	22600 (1.9)	–
4		C4	25 400 (2.4)	20 500 (1.6)
5	2	C1	43 700 (1.9)	1 500 (1.2)
6		C2	10 800 (1.7)	1 300 (1.1)
7		C3	37000 (2.2)	52600 (1.8)
8		C4	15 700 (1.5)	24 900 (1.5)
9	1 + 2	C4	–	28500 (1.6)
10	3	C4	34 400 (1.8)	50 800 (1.6)
11	4	C4	nd	3900 (1.7)
12	5	C4	nd	nd

ADMET polymerizations of (**2**) in Polarclean in the same reaction conditions were then launched. In the case of **C1** and **C2** (Table 1, entries 5^b and 6^b), only oligomers were achieved in low yields (around 20%), suggesting poor tolerance of these catalysts for the Polarclean solvent. The use of **C3** and **C4** (Table 1, entries 7^b and 8^b) was much more adapted regarding the higher molecular weights obtained in comparison to the other catalysts. It is noteworthy that solution polymerization of (**2**) by using **C3** and **C4** gave a polyester of higher molecular weight than bulk polymerization. It is ascribed to higher homogenization of the reaction mixture.

2.3 Tolerance Investigation of the Catalysts Toward Urethane Function

(1) was first polymerized in bulk while screening the metathesis catalysts to evaluate their tolerance toward the urethane function. As shown in Table 1 (entries 1^a and 2^a), **C1** led to higher molecular weight than **C2**. It can be correlated with the amount of isomerization, despite the presence of *p*-benzoquinone, more important in the case of the polymer synthesized with **C2** as shown from the ¹H NMR spectrum (see the peaks between 0.8 and 1 ppm in Figure S7b, Supporting Information). Hoveyda–Grubbs 1st generation catalyst, (**C3**), yielded higher molecular weight polymer than **C1**. Finally, Hoveyda–Grubbs 2nd generation catalyst, (**C4**), yielded polyurethanes with comparable molecular weight than the ones obtained with **C3**. Interestingly, lower molecular weights were found in the case of bulk ADMET of (1) than for ADMET of (2), except for **C4** that appears to be more relevant than the other catalysts. Consequently, we retained **C4** as a catalyst in the following.

2.4 Solution ADMET Polymerizations of (1) and Other α,ω -dienes

(1) was then polymerized in Polarclean, which led to a homogeneous reaction mixture. SEC analysis in THF showed a molecular weight of 20 500 g mol⁻¹. The completion of the polymerization was confirmed by ¹H NMR spectroscopy as seen from the decrease in the integration of the terminal olefin protons and the appearance of a multiplet at 5.37 ppm (Figure 2). All peaks were easily assigned except the chain ends, which should be terminal double bonds. The appearance of undesirable signals between 0.85 and 1.00 ppm suggests that some isomerization reactions took place, even in the presence of 1,4-benzoquinone, and that chain ends may consist in methyl groups. The introduction of ester functions in the polyurethane backbone was also carried out by copolymerizing (1) and (2) in equimolar ratio, with **C4** as a catalyst (Table 1, entry 9^b). The obtained copolymer exhibited a Mn of 28 500 g mol⁻¹ by SEC analysis with a dispersity of 1.6. Chemical composition of the copolymer, calculated from ¹H NMR analysis (Figure 2), was in agreement with the feed ratio.

To extend the palette of monomers polymerized through ADMET and obtained from 10-undecenoic acid platform, other bio-based α,ω -diene monomers bearing various organic functions were investigated. Monomers bearing carbonate (**3**)**19** (Figures S8 and S9, Supporting Information), ether (**4**)**20** (Figures S10 and S11, Supporting Information), and amide function (**5**) (Figure S12, Supporting Information) were synthesized and polymerized. ADMET polymerizations of (**3**), (**4**), and (**5**) were first conducted in bulk by using **C4** as a catalyst (Table 1, entries 10^a–12^a). An obvious increase of the viscosity of the reaction mixture was noticed in all cases; however, the polyamide and the polyether so-formed were insoluble in all the solvents generally used for SEC and NMR analysis, impeding their molecular characterization. The SEC analysis of the polycarbonate in THF showed a Mn of 34 400 g mol⁻¹ with a dispersity of 1.8. Polymerizations in Polarclean were then launched and showed evidence of polymer formation in all cases. The polycarbonate, analyzed by SEC in THF, presented a Mn of 50 800 g mol⁻¹, which is significantly higher than in bulk. Unlike the solution polymerizations of (1), (2), and (3), where the reaction mixtures were homogeneous, the polymerizations of (4) and (5) led to the precipitation of the polymers in Polarclean after a certain reaction time. Contrary to the polyether formed in bulk, the one synthesized in solution showed good solubility in THF, thus allowing its molecular characterization. A low Mn value of 3900 g mol⁻¹ was measured, which explains the better solubility in THF. This low molecular

weight was ascribed to the precipitation of the polymer in Polarclean during its formation, which limited the accessibility of the reactive sites. The polyamide was still not soluble in THF.

To summarize, Polarclean was revealed to be an effective solvent for ADMET polymerizations of **(1)**, **(2)**, and **(3)**, while it does not dissolve properly the polymers resulting from **(4)** and **(5)**.

2.5 Influence of Organic Functions on the Properties of the Resulting Polymers

Due to variations in the homogeneity of the reaction mixture during solution polymerizations, thermal investigations by DSC and TGA were performed with the polymers synthesized in bulk. Various thermal and thermomechanical behaviors were observed depending on the type of organic functions present in the polymer backbone. The lower thermal stability, determined by TGA, was observed for the polyurethane with an initial degradation temperature (temperature corresponding to 5 wt% loss: $T_{5\%}$) of 307 °C. The polycarbonate also showed a poor thermal stability ($T_{5\%} = 321$ °C). As expected, the polyamide, polyester, and polyether presented higher thermal stability with initial degradation temperatures of 343, 386, and 409 °C, respectively (Table 2).

Table 2. Thermal and thermomechanical characteristics of the polymers

Monomer	Polymer	T_c [°C] ^{a)}	T_m [°C] ^{a)}	ΔH_m [J g ⁻¹] ^{a)}	$T_{5\%}$ [°C] ^{b)}
1	Polyurethane	21	48	38	307
2	Polyester	43	53	89	386
1 + 2	Poly(ester-urethane)	35	55	55	325
3	Polycarbonate	36	36–49	13–39	321
4	Polyether	50	60	99	409
5	Polyamide	45	78	11	343

Determined by: ^{a)}DSC; ^{b)}TGA.

Regarding the thermomechanical properties evaluated by DSC analysis (Figure 3), the polyurethane exhibited a glass transition at –25 °C. This low value was attributed to the purely aliphatic nature of the polymer. A melting point was noticed with a corresponding temperature of 48 °C. The melting enthalpy was quite low (32 J g⁻¹) due to the remaining double bonds in the polymer structure, which restricts the chain packing and thus the

crystallinity. Interestingly, the polyester showed higher melting temperature (53 °C) and corresponding enthalpy (89 J g⁻¹) in comparison to the polyurethane. The copolymer from (1) and (2) showed intermediate thermomechanical properties in comparison to the polyester and the polyurethane, respectively (Figure S13, Supporting Information). In the case of the polycarbonate, a complex melting pattern was observed with two melting peaks (36 and 49 °C, respectively) on heating the sample, most probably ascribed to polymorphism or to melting-recrystallization processes. The DSC curve of the polyether showed a melting temperature of 60 °C with the higher melting enthalpy of 99 J g⁻¹. The high crystalline ability of the polyether is given by the conformational flexibility of the ether linkage, which promotes chain packing. As expected, of all the investigated polymers, the polyamide showed the highest melting temperature (78 °C) due to the high cohesion (and thus to the high stability of the crystals) that amide functions confer to the polymeric material.

Figure 3 DSC 2nd heating curves of a) polyurethane, b) polyester, c) polycarbonate, d) polyether, and e) polyamide.

3 Conclusion

We have demonstrated that ADMET polymerization of a α,ω -diene urethane monomer could be readily achieved in bulk and in Polarclean. This methodology thus offers new reaction conditions for polyurethane synthesis in comparison to the classical route (polyaddition of polyols and polyisocyanates) or to transurethanization pathway. Moreover, the use of Polarclean constitutes a greener alternative to common high boiling solvents employed in ADMET polymerizations. Other bio-based α,ω -diene monomers bearing various organic functions can also be polymerized by ADMET, which resulted in good efficiency of Polarclean as a polymerization solvent when carbonate and ester monomers were used. An overview of the thermomechanical properties of these polymers showed significant variations in the melting temperature and melting enthalpy values depending on the organic function present in the polymer backbone.

Experimental Section

Materials and Instrumentation

10-undecenoic acid (98%) was supplied by TCI, Europe. 1,5,7-triazabicyclo[4.4.0]dec-5-ene (TBD, 98%), triethylamine (99%), ethyl chloroformate (97%), sodium azide (99.99%), calcium hydride (95%), Grubbs 1st generation catalyst (C1), Grubbs 2nd generation catalyst (C2), Hoveyda-Grubbs 1st generation catalyst (C3) and Hoveyda-Grubbs 2nd generation catalyst (C4), dimethyl carbonate (99%), 4-toluenesulfonyl chloride (>99%), 11-bromo-1-undecene (95%), zinc dust (98%) and 10-undecenoyl chloride (>97%) were obtained from Sigma-Aldrich. 10-undecenol (99%) 1,4-benzoquinone (98%) and dibutyltin dilaurate (DBTDL, 95%) were purchased from Alfa Aesar. Methyl-5-(dimethylamino)-2-methyl-5-oxopentanoate (polarclean®) was kindly provided by Rhodia-Solvay. Polarclean was dried over CaH₂ and cryodistilled prior to use.

All NMR experiments were performed at 298 K on a Bruker Avance I NMR spectrometer operating at 400MHz and equipped with a Bruker multinuclear z-gradient direct probe head capable of producing gradients in the z direction with strength 53.5 G cm⁻¹. Infrared spectra were obtained on a Bruker-Tensor 27 spectrometer using the attenuated total reflection (ATR) mode. The spectra were acquired using 16 scans at a resolution of 4 wavenumbers. Size exclusion chromatography (SEC) analyses were performed in THF (40°C) on a PL-GPC 50

plus Integrated GPC from Polymer laboratories-Varian with a series of four columns from TOSOH (TSKgel TOSOH: HXL-L (guard column 6,0mm ID x 4,0cm L); G4000HXL (7,8mm ID x 30,0cm L) ;G3000HXL (7,8mm ID x 30,0cm L) and G2000HXL (7,8mm ID x 30,0cm L)). The elution of the filtered samples was monitored using simultaneous refractive index and UV detection. The elution times were converted to molar mass using a calibration curve based on low dispersity (M_w/M_n) polystyrene (PS) standards. The gas chromatography analyses (GC) were performed using a Shimadzu GC equipped with: Flame ionization detectors (FID, 380 °C) and Zebron ZB-5HT (5% phenyl - 95% dimethylpolysiloxane) 15 m x 0.25 mm ID, 0.1 μ m thickness capillary column. The carrier gas was hydrogen. The column temperature was initially set at 60 °C (volume injected: 1 μ l), then increased to 370 °C at a rate of 10 °C.min⁻¹ and held isothermally for 10 min. Differential scanning calorimetry (DSC) thermograms were measured using a DSC Q100 apparatus from TA instruments. Polymer samples were first heated from -100 to 120 °C and then the glass transition temperatures and melting points were calculated from a second heating run. All runs were performed at a rate of 10 °C min⁻¹. Thermogravimetric analyses (TGA) were performed on TGA-Q50 system from TA instruments at a heating rate of 10 °C.min⁻¹ under nitrogen atmosphere.

Synthesis of monomers

10-undecenoyl azide To a suspension of 10-undecenoic acid (8.9 g, 48.3 mmol) in tetrahydrofuran:water (50:15 mL) was added triethylamine (9.77 g, 96.6 mmol). The clear solution obtained was then cooled to 0 °C and then ethyl chloroformate (10.48 g, 96.6 mmol) was added drop-wise over a period of 10 min. The reaction mixture was stirred for 2 h and then NaN₃ (15.69 g, 241.5 mmol) in water (10 mL) was added drop-wise for 10 min and the stirring continued at 0 °C for 4 h. Icecold-water (20 mL) was added to the crude product which was then extracted with DCM (2 x 75 mL). The DCM solution was washed with water (3 x 40 mL), dried over sodium sulphate and filtered. The solvent was evaporated under reduced pressure at room temperature to obtain 10-undecenoyl azide as viscous oil. Yield:

82%. Organic acyl azides may be hazardous to manipulate due to their explosive tendency. Nevertheless, we voluntarily employed 10-undecenoic acid as a precursor to the acyl azide compound due to its long methylene chain which affords a sufficient ratio value of oxygen and carbon atoms numbers (N_C+N_O) to nitrogen atoms numbers (N_N). Indeed, for organic azides to be safely manipulated, $((N_C+N_O)/N_N)$ should be at least 3. In our case the ratio value is 4. The 10-undecenoyl azide can thus be manipulated if sufficient care is taken.

^1H NMR (CDCl_3 , δ/ppm): 5.82-5.70 (m, 1H, $-\text{CH}=\text{CH}_2$), 4.94-4.84 (m, 2H, $\text{CH}_2=\text{CH}-$), 3.28 (t, 2H, $-\text{CH}_2-\text{NCO}$), 2.32 (t, 2H, $-\text{CH}_2-\text{CON}_3$), 2.04 (q, 2H, $-\text{CH}_2-\text{CH}=\text{CH}_2$) 1.62 (m, 2H, $-\text{CH}_2-\text{CH}_2-\text{CON}_3$), 1.20-1.45 (m, 8H, $-\text{CH}_2-$).

Bis-unsaturated urethane (1) To a solution of undecylenic acyl azide (4.18 g, 20 mmol) in anhydrous THF, under nitrogen stream was slowly added 10-undecen-1-ol (**3**) (3.41 g, 20 mmol) and a drop of DBTDL. The reaction mixture was heated at 50 °C for overnight. After completion of reaction, the THF was evaporated under reduced pressure and to the crude product was added petroleum ether. The solid separated was filtered off and the filtrate concentrated on rotavapor to give bis-unsaturated urethane compound (**2**). The further purification was carried out using flash column chromatography (Pentane/ethyl acetate: 80/20). Yield: 63%.

^1H NMR (CDCl_3 , δ/ppm): 5.82-5.70 (m, 2H, $-\text{CH}=\text{CH}_2$), 4.94-4.84 (m, 4H, $\text{CH}_2=\text{CH}-$), 4.62 (m, 1H, $-\text{NH}-$), 4.03 (t, 2H, $-\text{CH}_2-\text{O}-\text{CO}-\text{NH}-$), 3.14 (q, 2H, $-\text{CH}_2-\text{NH}-\text{CO}-\text{O}-$), 2.04 (q, 4H, $-\text{CH}_2-\text{CH}=\text{CH}_2$), 1.59 (m, 2H, $-\text{CH}_2-\text{CH}_2-\text{O}-\text{CO}-\text{NH}-$), 1.47 (m, 2H, $-\text{CH}_2-\text{CH}_2-\text{NH}-\text{CO}-\text{O}-$), 1.20-1.40 (m, 22H, $-\text{CH}_2-$).

^{13}C NMR (CDCl_3 , δ/ppm): 156.80 ($-\text{NH}-\text{CO}-\text{O}-$), 139.20 ($-\text{CH}=\text{CH}_2$), 114.12 ($\text{CH}_2=\text{CH}-$), 64.89 ($-\text{CH}_2-\text{O}-\text{CO}-\text{NH}-$), 40.99 ($-\text{CH}_2-\text{NH}-\text{CO}-\text{O}-$), 33.73 ($-\text{CH}_2-\text{CH}=\text{CH}_2$), 25-31 ($-\text{CH}_2-$).

Bis-unsaturated ester (2) Methyl 10-undecenoate (15.00 g, 75.6mmol), 10-undecenol (12.87 g, 75.6mmol) and TBD (1: 1: 0.05) were stirred under nitrogen flow at 120 °C (4 h), at 160 °C (2 h) then under vacuum at 160 °C (1 h). After completion of the reaction, the product was

purified using flash column chromatography (Heptane/diethyl ether: 80/20). Yield: 81%. Purity by GC: 99%.

^1H NMR (CDCl_3 , δ /ppm): 5.82-5.70 (m, 2H, $-\text{CH}=\text{CH}_2$), 4.94-4.84 (m, 4H, $\text{CH}_2=\text{CH}-$), 4.05 (t, 2H, $-\text{CH}_2-\text{O}-\text{CO}-$), 2.28 (t, 2H, $-\text{CH}_2-\text{CO}-\text{O}-$), 2.04 (q, 4H, $-\text{CH}_2-\text{CH}=\text{CH}_2$), 1.59 (m, 2H, $-\text{CH}_2-\text{CH}_2-\text{O}-\text{CO}-$), 1.20-1.45 (m, 24H, $-\text{CH}_2-$).

Bis-unsaturated carbonate (3) 10-undecenol (20.8 g, 122.1mmol), dimethyl carbonate (5.50 g, 61.1mmol) and TBD (1: 0.5: 0.05) were stirred under nitrogen atmosphere at 80 °C (2 h), and then under nitrogen flow at the same temperature (4 h) then under vacuum at 80°C (1 h). After completion of the reaction, the product was purified using flash column chromatography (Heptane/ethyl acetate: 90/10). Yield: 75%. Purity by GC: 99%.

^1H NMR (CDCl_3 , δ /ppm): 5.82-5.70 (m, 2H, $-\text{CH}=\text{CH}_2$), 4.94-4.84 (m, 4H, $\text{CH}_2=\text{CH}-$), 4.11 (t, 4H, $-\text{CH}_2-\text{O}-\text{CO}-\text{O}$), 2.04 (q, 4H, $-\text{CH}_2-\text{CH}=\text{CH}_2$), 1.66 (m, 4H, $-\text{CH}_2-\text{CH}_2-\text{O}-\text{CO}-\text{O}$), 1.20-1.45 (m, 24H, $-\text{CH}_2-$).

1-tosyl-10-undecene Into a two necked round bottom flask equipped with magnetic stirrer and additional funnel, 10-undecen-1-ol (10 g, 58.82 mmol) and triethylamine (5.95 g, 58.82 mmol) were dissolved in dichloromethane (100 mL). The solution was cooled at 0 °C in an ice bath. Solution of 4-toluenesulfonyl chloride (11.17 g, 58.82 mmol) in dichloromethane (25 mL) was slowly added to the cooled solution through additional funnel. The reaction mixture was stirred at 0 °C for 2 h and at room temperature overnight. The reaction mixture was filtered and the organic layer was washed with 5% NaHCO_3 (3 x 100 mL) and water (3 x 100 mL). The organic layer was dried over anhydrous sodium sulphate, filtered and chloroform was evaporated under reduced pressure. The crude product was purified by silica gel column chromatography using a mixture of ethyl acetate: petroleum ether (10:90, v/v) as eluent. The removal of the solvent yielded 18.70 g (98 %) of 1-tosyl-10-undecene as a pale yellow liquid.

^1H NMR (CDCl_3 , δ/ppm): 7.74 (d, 2H, Ar-H), 7.25 (d, 2H, Ar-H), 5.82-5.70 (m, 1H, -CH=CH₂), 4.94-4.84 (m, 2H, CH₂=CH-), 3.96 (t, 2H, -OCH₂-), 2.37 (s, 3H, -CH₃), 2.04 (q, 2H, -CH₂-CH=CH₂), 1.56 (m, 2H, -CH₂-CH₂-O-), 1.20-1.45 (m, 12H, -CH₂-).

Bis-unsaturated ether (4) Into a two necked round bottom flask equipped with magnetic stirrer, slurry of sodium hydride (0.576 g, 23.52 mmol) in dimethylsulfoxide (25 mL) was formed. Solution of 10-Undecen-1-ol (1.0 g, 5.88 mmol) in dimethylsulfoxide (10 mL) was slowly added. The reaction mixture was stirred at room temperature for 10 minutes. To this, 1-tosyl-10-Undecene (1.81 g, 5.88 mmol) was added slowly. After 12h, dimethylsulfoxide was removed under reduced pressure and excess sodium hydride was deactivated by aqueous solution of ammonium chloride. Dichloromethane (50 mL) was added. The organic layer was washed with 5% NaHCO₃ (3 x 100 mL) and water (3 x 100 mL). The organic layer was dried over anhydrous sodium sulphate, filtered and chloroform was evaporated under reduced pressure. The crude product was purified by silica gel column chromatography using a mixture of ethyl acetate: petroleum ether (5:95, v/v) as eluent. Yield: 88%. Purity by GC: 99%.

^1H NMR (CDCl_3 , δ/ppm): 5.82-5.70 (m, 2H, -CH=CH₂), 4.94-4.84 (m, 4H, CH₂=CH-), 3.31 (t, 4H, -O-CH₂-), 2.04 (q, 4H, -CH₂-CH=CH₂), 1.47 (m, 4H, -CH₂-CH₂-O-), 1.20-1.45 (m, 24H, -CH₂-).

1-azido-10-undecene To a 250mL, round-bottom flask equipped with a stirring bar, sodium azide (9.56 g, 147mmol) and 40mL of dimethylformamide (DMF) were transferred. To the stirred solution, 1-bromo-10-undecene (8.57 g, 37mmol) was added dropwise, and the entire mixture was allowed to stir for 12h. The azide mixture was then transferred to a separating funnel and extracted with ether and water at a ratio 1:1. The ether layer was washed with water three times to remove DMF, dried over anhydrous sodium sulphate and concentrated under reduced pressure to end-up with 1-azido-10-undecene compound. Yield: 81%.

^1H NMR (CDCl_3 , δ/ppm): 5.82-5.70 (m, 1H, $-\text{CH}=\text{CH}_2$), 4.94-4.84 (m, 2H, $\text{CH}_2=\text{CH}-$), 3.25 (t, 2H, $-\text{CH}_2-\text{N}_3$), 2.04 (q, 2H, $-\text{CH}_2-\text{CH}=\text{CH}_2$), 1.58 (m, 2H, $-\text{CH}_2-\text{CH}_2-\text{N}_3$), 1.20-1.45 (m, 12H, $-\text{CH}_2-$).

1-amino-10-undecene Reduction of azide to amine was performed by following reported procedures.²¹ To a solution of azide (6 g, 30.7mmol) and ammonium chloride (7.49 g, 140mmol) in ethyl alcohol and water (150: 50/v: v), zinc dust (3.9 g, 60mmol) was added, the mixture was stirred vigorously at refluxing for 1h. After the reaction is over, ethyl acetate and aqueous ammonia (20mL) was added. The mixture was filtered, and the filtrate was washed with brine, dried over anhydrous sodium sulfate and concentrated under reduced pressure. Yield: 63%.

^1H NMR (CHCl_3 , δ/ppm): 5.82-5.70 (m, 1H, $-\text{CH}=\text{CH}_2$), 4.94-4.84 (m, 2H, $\text{CH}_2=\text{CH}-$), 2.67 (t, 2H, $-\text{CH}_2-\text{NH}_2$), 2.04 (q, 2H, $-\text{CH}_2-\text{CH}=\text{CH}_2$), 1.42 (m, 2H, $-\text{CH}_2-\text{CH}_2-\text{NH}_2$), 1.20-1.45 (m, 12H, $-\text{CH}_2-$).

Bis-unsaturated amide (5) To a 500mL, round-bottom flask equipped with a stirring bar, a solution of triethylamine (2.69 g, 26.6mmol) and 1-amino-10-undecene (3 g, 17.75mmol) in THF was transferred. 10-undecenoyl chloride (3.60 g, 17.75mmol) was added dropwise to the solution at 0°C . After addition, the reaction mixture was stirred for 24h at room temperature under nitrogen atmosphere. After completion of the reaction, the obtained suspension was filtered to remove triethylamine salt and THF was removed under reduced pressure. The product was purified by column chromatography using a mixture of cyclohexane: ethyl acetate (90:10 / v: v). The bis-unsaturated amide was obtained as a light yellow solid. Yield: 69%.

^1H NMR (CDCl_3 , δ/ppm): 5.82-5.70 (m, 2H, $-\text{CH}=\text{CH}_2$), 4.94-4.84 (m, 4H, $\text{CH}_2=\text{CH}-$), 3.24 (t, 2H, $-\text{CH}_2-\text{NH}-\text{CO}-$), 2.14 (t, 2H, $-\text{CH}_2-\text{CO}-\text{NH}-$), 2.04 (q, 4H, $-\text{CH}_2-\text{CH}=\text{CH}_2$), 1.62 (m, 2H, $-\text{CH}_2-\text{CH}_2-\text{NH}-\text{CO}-$), 1.20-1.45 (m, 24H, $-\text{CH}_2-$).

Polymerization reactions

Polymerizations in solution. Typical procedure for the solution polymerization in *Polarclean* was as follow. Monomers were dried under vacuum at 70°C overnight prior to use. In a round-bottom flask was transferred a solution of the monomer with 0.5mol% of metathesis catalyst (and 5mol% of 1,4-benzoquinone in the case of ruthenium 2nd generation catalysts) in *polarclean*. The reaction mixture was stirred at 80°C for 24h under dynamic vacuum. After completion of the reaction, ethylvinyl ether was added and the mixture was stirred at room temperature for 30 minutes under nitrogen atmosphere to deactivate metathesis catalyst. Dynamic vacuum was then applied to remove excess ethylvinyl ether. The reaction mixture was then precipitated in methanol in order to remove all the *polarclean* solvent. Polymers were finally dried overnight at 70°C under dynamic vacuum.

Polymerizations in bulk. All monomers were dried under vacuum at 70°C overnight prior to reaction. In a round-bottom flask was transferred the monomer feed, with 0.5mol% of metathesis catalyst (and 5mol% of 1,4-benzoquinone in the case of ruthenium 2nd generation catalysts). The reaction mixture was stirred at 80°C for 24h under dynamic vacuum. Tetrahydrofuran (THF) and ethylvinyl ether were then added and the mixture was stirred at room temperature for 30 minutes under nitrogen atmosphere. Dynamic vacuum was then applied. The reaction mixture was dissolved in dichloromethane and the polymer was precipitated in methanol and dried overnight at 70°C under vacuum.

All polymerizations in bulk and in solution led to a yield between 50 and 75%. Only the polyesters synthesized in *Polarclean* from (2) by using C1 and C2 were obtained with a lower yield of around 20% and the polyether synthesized in *Polarclean*, which was obtained with a 38% yield.
