Non Linear Singular Drifts and Fractional Operators: when Besov meets Morrey and Campanato

Diego Chamorro*, Stéphane Menozzi†

June 1, 2017

Abstract

Within the global setting of singular drifts in Morrey-Campanato spaces presented in [7], we study now the Hölder regularity properties of the solutions of a transport-diffusion equation with nonlinear singular drifts that satisfy a Besov stability property. We will see how this Besov information is relevant and how it allows to improve previous results. Moreover, in some particular cases we show that as the nonlinear drift becomes more regular, in the sense of Morrey-Campanato spaces, the additional Besov stability property will be less useful.

Keywords: Besov spaces; Morrey-Campanato spaces; Hölder regularity.

1 Introduction

In a previous work [7] we studied smoothness properties of the solutions $\theta : [0, +\infty[\times \mathbb{R}^n \rightarrow \mathbb{R}$ of a *linear* transport-diffusion equation of the following form

$$\partial_t \theta - \nabla \cdot (v \theta) + \mathcal{L}^{\alpha_0} \theta = 0, \quad (1.1)$$

with a divergence-free velocity field $v : [0, +\infty[\times \mathbb{R}^n \rightarrow \mathbb{R}^n$ for which we had a uniform control in the space $L^\infty([0, T], M^{q,a}(\mathbb{R}^n))$, where $M^{q,a}(\mathbb{R}^n)$ stands for the Morrey-Campanato space with parameters q, a whose definition is recalled below, and with a *diffusion* term that was given by a general non-degenerate *stable-like* Lévy operator \mathcal{L}^{α_0} of Blumenthal-Gettoor index $0 < \alpha_0 < 2$, *i.e.* in a neighborhood of 0 its symbol $\widehat{\mathcal{L}}^{\alpha_0}$ is upper and lower bounded by $|\xi|^{\alpha_0}$. We will refer to α_0 as the smoothness degree of the operator \mathcal{L}^{α_0} .

We proved in this article that if we take as starting point an initial data $\theta_0 \in L^\infty(\mathbb{R}^n)$ and if the linear drift v belongs to a Morrey-Campanato space $M^{q,a}(\mathbb{R}^n)$ whose parameters q, a and the smoothness degree α_0 of the Lévy operator are related with the dimension n by the relationship

$$\frac{a - n}{q} = 1 - \alpha_0, \quad (1.2)$$

then, weak solutions of equation (1.1) belong to a Hölder space $\mathcal{C}^\gamma(\mathbb{R}^n)$ with $0 < \gamma < 1$. In the case of the fractional Laplacian, relation (1.2) readily follows from the homogeneity structure of equation (1.1).

*Laboratoire de Mathématiques et Modélisation d'Evry, Université d'Evry Val d'Essonne, France.

†Laboratoire de Mathématiques et Modélisation d'Evry, Université d'Evry Val d'Essonne, France & Laboratory of Stochastic Analysis, HSE, Moscow, Russia.

This actually yields a gain in regularity as $\theta_0 \in L^\infty(\mathbb{R}^n)$. Remark moreover that a small regularity index γ is enough for our purposes since it is possible to apply bootstrap arguments to obtain higher regularity, see [3], Section B, for the details. It is also worth noting here that the relationship (1.2) is given by the equation's homogeneity and without any further information over the velocity field v it is not possible to break it down as in some particular cases counterexamples can be exhibited, see [23].

We will adopt from now on the following notation: the index α_0 will denote the smoothness degree of the operator \mathcal{L}^{α_0} in the *linear* setting given by equation (1.1) and it will be always related to the dimension n and the parameters of the Morrey-Campanato space q, a , by the equation (1.2).

Recall now that Lévy-type operators \mathcal{L}^{α_0} are, roughly speaking, generalizations of the fractional Laplacian $(-\Delta)^{\frac{\alpha_0}{2}}$ and the choice of Morrey-Campanato spaces $M^{q,a}$ (with $1 < q < +\infty$ and $0 \leq a < n + q$) was given by the fact that they can describe both singular and regular situations following the values of the parameters q and a : indeed, if $0 \leq a < n$ the corresponding spaces are singular (Morrey spaces) while if $n < a < n + q$ we obtain the following identification with Hölder spaces $M^{q,a}(\mathbb{R}^n) \simeq \mathcal{C}^\lambda(\mathbb{R}^n)$ where $\frac{a-n}{q} = \lambda$ and $\lambda \in]0, 1[$. The case $a = n$ is given by the space $bmo(\mathbb{R}^n)$. See Section 2 below for a precise definition of these operators and spaces.

The aim of this article is then to consider singular and *nonlinear* divergence-free velocity fields with some additional stability properties in order to break down the relationship (1.2) in the following sense: we want to obtain a smaller regularity degree $0 < \alpha < \alpha_0 < 2$ for the operator \mathcal{L}^α such that we still can obtain Hölder regularity for the associated solutions. The main ingredient to achieve this goal is to use the extra information given by the boundedness properties of the nonlinear drift (given in terms of Besov spaces): indeed, for a function $\theta : [0, +\infty[\times \mathbb{R}^n \rightarrow \mathbb{R}$, with $n \geq 2$, we consider the problem

$$\partial_t \theta - \nabla \cdot (A_{[\theta]} \theta) + \mathcal{L}^\alpha \theta = 0, \quad (1.3)$$

where \mathcal{L}^α is a Lévy-type operator of regularity degree $0 < \alpha < 2$ and $A_{[\theta]}$ is a nonlinear velocity field satisfying the following general hypotheses:

- $A_{[\theta]}$ is given as a vector of singular integrals of convolution type:

$$A_{[\theta]}(t, x) = [A_1(\theta)(t, x), \dots, A_n(\theta)(t, x)], \quad (n \geq 2), \quad (1.4)$$

with $A_i(\theta)(t, x) = v.p. \int_{\mathbb{R}^n} \kappa_i(x - y) \theta(t, y) dy$ and where $\kappa_i = \kappa_i(x)$ is the associated kernel of the singular integral operator A_i for $1 \leq i \leq n$.

- The nonlinear drift $A_{[\theta]}$ is divergence free.
- The nonlinear drift $A_{[\theta]}$ satisfies some boundedness properties in Morrey-Campanato spaces $M^{q,a}(\mathbb{R}^n)$ with $1 \leq q < +\infty$ and $0 \leq a < n$.
- The operator $A_{[\theta]}$ is bounded in Besov spaces $\dot{B}_q^{s,p}(\mathbb{R}^n)$ with $0 \leq s < 1$ and $1 \leq p, q \leq +\infty$.

Let us make some remarks about the hypotheses over the nonlinear drift $A_{[\theta]}$. First, the singular integral setting given by (1.4) allows us to consider a wide range of operators with remarkable properties studied in many books (see for example [24], [25], [2]). Next, the divergence free condition is very natural in problems arising from fluid dynamics and this property is crucial in this work as it considerably simplifies the computations.

These types of nonlinear drifts appear in many applicative fields. We mention for instance the surface quasi-geostrophic equation (SQG), see e.g. [3], for which $A_{[\theta]}(t, x) = [-R_2 \theta(t, x), R_1 \theta(t, x)]$

where $(R_j)_{j \in \{1,2\}}$ denote the Riesz transforms *i.e.* $\widehat{R_j \theta}(t, \xi) = -i \frac{\xi_j}{|\xi|} \widehat{\theta}(t, \xi)$. Other examples derived from magnetohydrodynamic equations (MHD) have been studied in the limit case $\alpha = 2$ by Friedlander and Vicol [14]. They consider drifts of the form $(A_{[\theta]})_j(t, x) = \sum_{i=1}^n \partial_i T_{ij} \theta(t, x)$ where $\{T_{ij}\}$ is an $n \times n$ matrix of Calderón-Zygmund singular integral operators such that $\sum_{i,j=1}^n \partial_i \partial_j T_{ij} = 0$, which guarantees the divergence free condition.

The boundedness of the drift in terms of Morrey-Campanato spaces was already used (in a linear setting) in [7] but it will be used here in order to ensure existence issues (but not only!) and we will see how this boundedness hypothesis interacts with the solution's regularity.

The main novelty of this article relies in the handling of a Besov space boundedness condition for the nonlinear velocity field $A_{[\theta]}$ combined with the maximum principle $\|\theta(\cdot, \cdot)\|_{L^\infty(L^p)} \leq \|\theta_0\|_{L^p}$ which is satisfied by (weak) solutions of equation (1.3). Indeed, for a fixed final $T > 0$ we can prove from the study of the maximum principle (see Section 3 of the current work and Sections 2.2 and 2.3 in [7] for details, see also [12]) that

$$\|\theta(T, \cdot)\|_{L^p}^p + p \int_0^T \int_{\mathbb{R}^n} |\theta(t, x)|^{p-2} \theta(t, x) \mathcal{L}^\alpha \theta(t, x) dx dt \leq \|\theta_0\|_{L^p}^p,$$

from which we obtain the control

$$p \int_0^T \int_{\mathbb{R}^n} |\theta(t, x)|^{p-2} \theta(t, x) \mathcal{L}^\alpha \theta(t, x) dx dt \leq \|\theta_0\|_{L^p}^p. \quad (1.5)$$

Recalling as well from [7] (see also [5]) that for $0 < t < T$ we have

$$\|\theta(t, \cdot)\|_{\dot{B}_p^{\frac{\alpha}{p}, p}}^p \leq C \left(\|\theta(t, \cdot)\|_{L^2}^{p/2} + \int_{\mathbb{R}^n} |\theta(t, x)|^{p-2} \theta(t, x) \mathcal{L}^\alpha \theta(t, x) dx \right),$$

we thus derive from the maximum principle and from (1.5) the following bound

$$\int_0^T \|\theta(t, \cdot)\|_{\dot{B}_p^{\frac{\alpha}{p}, p}}^p dt \leq C(T) \|\theta_0\|_{L^p}^p, \quad (1.6)$$

yielding $\theta \in L^p([0, T], \dot{B}_p^{\frac{\alpha}{p}, p})$. The fact that the quantity in the l.h.s. of (1.5) expresses regularity in terms of Besov spaces was already observed in [10] (see as well [5], [7] and Theorem 5 below) but it seems that it was not fully used to study the regularity of the solution of this type of equations. We mention that the regularity conveyed by the Besov space $\dot{B}_p^{\frac{\alpha}{p}, p}$ is only related to the initial data $\theta_0 \in L^p$ and to the smoothness degree α of the Lévy-type operator. Now, in order to link this Besov information with the behavior of the drift, we will assume the following boundedness condition:

$$\|A_{[\theta]}\|_{L^p([0, T], \dot{B}_q^{s, p})} \leq C \|\theta\|_{L^p([0, T], \dot{B}_p^{\frac{\alpha}{p}, p})}. \quad (1.7)$$

In this article we will show how to use this additional Besov regularity given by (1.7) and (1.6) in order to by-pass the Morrey-Campanato boundedness hypothesis and we will study how to break down the relationship (1.2): within this general framework we will see that if the initial data θ_0 belongs to a Lebesgue space L^p and if the parameter p that characterizes this initial condition, the Morrey-Campanato indexes q, a and the regularity degree α of the Lévy-type operator are *suitably*

related, then it is possible to obtain Hölder regularity for the solutions of equation (1.3) and moreover we obtain that the corresponding value of the regularity degree α satisfies $\alpha < \alpha_0$ where α_0 was given in relationship (1.2): we will thus obtain results that are out of reach in our previous work [7].

The main ideas for the proofs are again based on the Hardy-Hölder duality which was already the cornerstone in [7] and we now specifically exploit the additional Besov information to improve the results (see Remark 4.5 for details).

It is worth noting here that there are two situations where this extra regularity information is not as relevant as expected. The first one is related to inequalities (1.7) and (1.6) which express the fact that the Besov regularity $\dot{B}_p^{\frac{\alpha}{p}, p}$ is linked to the initial data $\theta_0 \in L^p$ and if we made $p \rightarrow +\infty$ we would completely lose this regularity information. The second one is related to the nonlinear drift: we are able to use this extra Besov regularity information as long as the drift belongs to a singular Morrey-Campanato space (*i.e.* if $0 \leq a < n$) but we do not know if it is possible to exploit the Besov information in a more regular Morrey-Campanato framework (*i.e.* if $n < a < n + q$). Recall that when $n < a < n + q$, Morrey-Campanato spaces are equivalent to classical Hölder spaces since $M^{q,a}(\mathbb{R}^n) \simeq \mathcal{C}^\lambda(\mathbb{R}^n)$ where $\frac{a-n}{q} = \lambda$ with $\lambda \in]0, 1[$, and the Besov regularity is probably too weak to improve this already regular setting.

Our last remark concerns the fact that Besov and Morrey-Campanato boundedness properties are not very restrictive conditions as all standard (and reasonable) Calderón-Zygmund operators are bounded in these functional spaces. See [24] and [2] for more details about this fact.

The plan of the article is the following. In Section 2 we give the precise definition of Lévy-type operators used in equation (1.3) and we recall the definition and some useful properties of Morrey-Campanato and Besov spaces. We also state in this section the main theorems and results of the article that emphasize that, according to the assumptions on the nonlinear velocity field, different results are obtained. In particular, we will show then an interesting competition between the Morrey-Campanato information and the Besov regularity. In Section 3 we discuss some existence issues for this nonlinear PDE. Finally, Section 4 is devoted to the proofs.

2 Notation and Presentation of the results

We start with the definition of the Lévy-type operator \mathcal{L}^α used in equation (1.3). These operators are natural generalizations of the fractional Laplacian $(-\Delta)^{\frac{\alpha}{2}}$, with $0 < \alpha < 2$, which is given in the Fourier variable by the expression $\widehat{(-\Delta)^{\frac{\alpha}{2}}\varphi}(\xi) = c|\xi|^\alpha \widehat{\varphi}(\xi)$, for all suitable regular enough functions φ . Thus, following this approach, we define the operator \mathcal{L}^α by the expression

$$\widehat{\mathcal{L}^\alpha\varphi}(\xi) = a(\xi)\widehat{\varphi}(\xi), \quad (2.1)$$

here the symbol a is given by the so-called Lévy-Khinchin formula

$$a(\xi) = \int_{\mathbb{R}^n \setminus \{0\}} (1 - \cos(\xi \cdot y)) \pi(y) dy,$$

where the function π is symmetric, *i.e.* $\pi(y) = \pi(-y)$ for all $y \in \mathbb{R}^n$ and satisfies the bounds

$$\begin{aligned} \bar{c}_1 |y|^{-n-\alpha} \leq \pi(y) \leq \bar{c}_2 |y|^{-n-\alpha} & \quad \text{over } |y| \leq 1, \\ 0 \leq \pi(y) \leq \bar{c}_2 |y|^{-n-\delta} & \quad \text{over } |y| > 1, \end{aligned} \quad (2.2)$$

here $0 < \bar{c}_1 \leq \bar{c}_2$ are positive constants and where $0 < \delta < \alpha < 2$. The important point here is that the parameter α (called the *smoothness degree*) will rule the smoothness properties of the operator \mathcal{L}^α in the sense that for such α the regularizing effect of \mathcal{L}^α is similar to the fractional Laplacian $(-\Delta)^{\frac{\alpha}{2}}$. See [16] for additional properties concerning Lévy operators and the Lévy-Khinchin formula.

We define now local Morrey-Campanato spaces $M^{q,a}(\mathbb{R}^n)$ for $1 \leq q < +\infty$, $0 \leq a < n + q$ by the condition:

$$\|f\|_{M^{q,a}} = \sup_{\substack{x_0 \in \mathbb{R}^n \\ 0 < r < 1}} \left(\frac{1}{r^a} \int_{B(x_0,r)} |f(x) - \bar{f}_{B(x_0,r)}|^q dx \right)^{1/q} + \sup_{\substack{x_0 \in \mathbb{R}^n \\ r \geq 1}} \left(\frac{1}{r^a} \int_{B(x_0,r)} |f(x)|^q dx \right)^{1/q} < +\infty,$$

where $\bar{f}_{B(x_0,r)} = \frac{1}{|B(x_0,r)|} \int_{B(x_0,r)} f(y) dy$ is the average of the function f over the ball $B(x_0,r)$.

Remark that if $a = 0$ and $1 \leq q < +\infty$ we have $L^q \subset M^{q,0}$. When $a = n$ and $q = 1$ the space $M^{1,n}(\mathbb{R}^n)$ corresponds to the space *bmo* (the local version of *BMO*) and from this fact we derive the identification $M^{1,n} \simeq M^{q,n}$ for $1 < q < +\infty$. Finally, if $n < a < n + q$ and $1 \leq q < +\infty$, we obtain $M^{q,a}(\mathbb{R}^n) = \mathcal{C}^\lambda(\mathbb{R}^n)$, classical Hölder space with $0 < \lambda = \frac{a-n}{q} < 1$. The case $n + q \leq a$ will not be considered as the corresponding spaces are reduced to constants.

Remark 2.1 *As we can see, if we consider the range of values $0 \leq a < n$, the Morrey-Campanato space $M^{q,a}$ becomes less singular as the value of the parameter a increases.*

Finally, when $0 \leq a < n$, the Hölder inequality easily yields the following embedding :

$$L^p(\mathbb{R}^n) \subset M^{q,a}(\mathbb{R}^n) \quad \text{with } p = \frac{qn}{n-a}. \quad (2.3)$$

This particular fact suitably combined with a maximum principle will be quite useful in the following lines. See [1], [20] and [26] for more details concerning Morrey-Campanato spaces.

For $0 < s < 2$ and $1 \leq q \leq +\infty$, homogeneous Besov spaces $\dot{B}_q^{s,p}(\mathbb{R}^n)$ may be defined by the condition

$$\|f\|_{\dot{B}_q^{s,p}} = \left(\int_{\mathbb{R}^n} \frac{\|f(\cdot + y) + f(\cdot - y) - 2f(\cdot)\|_{L^p}^q dy}{|y|^{n+sq}} \right)^{1/q} < +\infty.$$

However, in the particular case when $0 < s < 1$ and $p = q$, the previous condition can be replaced by the following one which will be used in the sequel:

$$\|f\|_{\dot{B}_p^{s,p}} = \left(\int_{\mathbb{R}^n} \int_{\mathbb{R}^n} \frac{|f(x) - f(y)|^p}{|x - y|^{n+sp}} dx dy \right)^{1/p} < +\infty. \quad (2.4)$$

For more details about Besov spaces see the monograph [22].

From now on we will always assume that \mathcal{L}^α is a Lévy-type operator of the form (2.1) satisfying hypothesis (2.2) with a smoothness degree $0 < \alpha < 2$ and for the nonlinear drift $A_{|\theta|}$ we assume that it is given as a divergence free vector of singular integrals of convolution type as in (1.4).

With these ingredients, and for a initial data θ_0 , we consider now the following nonlinear equation for a function $\theta : [0, +\infty[\times \mathbb{R}^n \rightarrow \mathbb{R}$ with $n \geq 2$:

$$\begin{cases} \partial_t \theta(t, x) - \nabla \cdot (A_{|\theta|} \theta)(t, x) + \mathcal{L}^\alpha \theta(t, x) = 0, \\ \theta(0, x) = \theta_0(x), \quad \text{for all } x \in \mathbb{R}^n. \end{cases} \quad (2.5)$$

In the following, for a time-space function $v : [0, T] \times \mathbb{R}^n \rightarrow \mathbb{R}$, such that $v \in L^p([0, T], X)$, where X is a function space and $p \in [1, +\infty]$, we write $\|v\|_{L^p(X)} := \|v\|_{L^p([0, T], X)}$. We will take as possible spaces for X , $L^p = L^p(\mathbb{R}^n)$, $M^{q,a} = M^{q,a}(\mathbb{R}^n)$, $\dot{B}_q^{s,p} = \dot{B}_q^{s,p}(\mathbb{R}^n)$.

We have now all the notation and definition that will allow us to state our first theorem.

Theorem 1 (General Framework) *Consider equation (2.5) above and assume the following points:*

- 1) *The initial data θ_0 belongs to a Lebesgue space $L^p \cap L^\infty(\mathbb{R}^n)$ with $n(n-1) \vee 2n < p < +\infty$,*
- 2) *The operator $A_{[\theta]}$ that defines the nonlinear drift in equation (2.5) above is*
 - (a₁) *bounded in Morrey-Campanato spaces $M^{q,a}$ with $(n-a)(n-1) \vee 2n \leq q < +\infty$ and $0 \leq a < n$,*

$$\|A_{[\theta]}\|_{L^\infty(M^{q,a})} \leq C_A \|\theta\|_{L^\infty(M^{q,a})} \quad (0 \leq a < n), \quad (2.6)$$

- (b₁) *bounded in Besov spaces $\dot{B}_p^{\frac{\alpha}{p}, p}$,*

$$\|A_{[\theta]}\|_{L^p(\dot{B}_p^{\frac{\alpha}{p}, p})} \leq D_A \|\theta\|_{L^p(\dot{B}_p^{\frac{\alpha}{p}, p})}, \quad (2.7)$$

where $1 < \alpha < 2$ is the regularity degree of the operator \mathcal{L}^α and $1 < p < +\infty$ is given in the previous point 1) above.

If the index p defining the initial data Lebesgue space L^p , the regularity degree α of the Lévy-type operator \mathcal{L}^α and the parameters q, a of the Morrey-Campanato space $M^{q,a}$ are related by the conditions

$$p = \frac{qn}{n-a}, \quad \text{and} \quad 1 < \alpha = \frac{p+n}{p+1} < 2, \quad (2.8)$$

then the solution $\theta(t, \cdot)$ of the equation (2.5) belongs to a Hölder space $C^\gamma(\mathbb{R}^n)$ for $0 < \gamma < \frac{1}{4}$ small.

Moreover, the regularity degree α given in (2.8) using the Besov stability property of the drift is always less than the degree α_0 given in (1.2) which can be deduced from the Morrey-Campanato boundedness property.

Remark now that we take as initial data a function that belongs to the space $L^p \cap L^\infty$: the L^∞ information is needed to apply the regularity results of [7] and to obtain a general existence framework while the L^p control is needed in order to use the Morrey-Campanato and Besov regularity information.

The lower bound $n(n-1) \vee 2n < p$ stated for the initial data is given in this form for the sake of simplicity and it is mostly related to computational issues. It guarantees that the results from [7] apply and that the Morrey-Campanato information (2.6) yields to the relation (1.2) to derive the expected regularization property. A more accurate bound on p would depend on the smoothness degree α and some other technical parameters (see Section 4 and Theorem 2 of [7])¹. Remark also that, since p and q are related by the first equality of (2.8), the condition $(n-a)(n-1) \vee 2n \leq q < +\infty$

¹For Theorem 2 in [7] to apply, the constraint $\frac{\alpha}{\alpha-1} > n$ is needed. Since $\alpha = \frac{p+n}{p+1}$, this first gives $p > n(n-2)$. On the other hand, to compare with the usual homogeneity relation (1.2), we need this constraint to be fulfilled as well by $\alpha_0 = 1 - \frac{\alpha-n}{q}$. Since p and q are related by (2.8), we then get $p > n(n-1)$. Eventually, the condition $q > \frac{n}{1-\gamma}$ also appears in Theorem 2 of [7]. Choosing $\gamma < \frac{1}{4}$, (2.8) yields that this last condition is satisfied for $p > 2n$.

is a consequence of the previous bound on p .

Observe that we have imposed two conditions over the nonlinear drift: a Morrey-Campanato control (2.6) and a Besov control (2.7) and it is interesting to study which one of these conditions gives a better result in the sense that the corresponding smoothness degree α needed to deduce Hölder continuity is as low as possible.

From the Morrey-Campanato control (2.6) and recalling that we have the first relationship of (2.8) between the parameters p, n, q and a , we can use the Morrey-Campanato-Lebesgue embedding (2.3). Combining this fact with the maximum principle (see point (iii), page 15 and the computations performed in (3.5)-(3.6)) we have $\|A_{[\theta]}\|_{L^\infty(M^{q,a})} \leq C_A \|\theta\|_{L^\infty(M^{q,a})} \leq C_A \|\theta\|_{L^\infty(L^p)} \leq C_A \|\theta_0\|_{L^p} < +\infty$. Thus, we can apply the results given in [7] to obtain a smoothness degree α_0 given by the initial relationship (1.2).

But using the Besov stability hypothesis (2.7) we have a stronger result since in this case we always obtain a corresponding smoothness degree α such that $1 < \alpha < \alpha_0 < 2$. Indeed, following (1.2) we have $\alpha_0 = \frac{q+n-a}{q}$ but since p is related to q by (2.8), we obtain that $\alpha_0 = \frac{p+n}{p} > \frac{p+n}{p+1} = \alpha$: the Besov regularity information allows us to improve the general result.

Remark now that, by definition we have $\alpha = \frac{p+n}{p+1} > 1$ and, although we can break down the relationship (1.2), the effect of the Besov regularity information is not strong enough to obtain a corresponding smoothness degree α such that $0 < \alpha < 1$.

Note also that, if we let $a \rightarrow n$, then the Morrey-Campanato space $M^{q,a}$ becomes *less singular* and gets closer to the bounded mean oscillation space $bmo \simeq M^{q,n}$ (recall Remark 2.1), we thus have from the relationship (2.8) that $p \rightarrow +\infty$ so that the additional regularity information given by (2.7) vanishes -we lose all the extra regularity information- and we obtain in this limit $\alpha \rightarrow 1$. This framework corresponds to an L^∞ initial data, a drift term in bmo and a diffusion term of regularity degree $\alpha = 1$ and this particular situation was first studied in [3] and then generalized in [6].

Theorem 1 gives a natural and general framework since conditions (2.6) and (2.7) are not very restrictive ones. As said in the introduction, a wide family of Calderón-Zygmund operators satisfy these hypotheses (for more details see [2] for Morrey-Campanato spaces and [18], [19] for Besov spaces).

In the next theorem we will show an interesting competition between the Morrey-Campanato and the Besov regularity. Indeed, we will assume here a different Morrey-Campanato boundedness behavior for the nonlinear drift $A_{[\theta]}$ and following Remark 2.1 we will see that, under special hypotheses, as long as the parameter a of the Morrey-Campanato space $M^{q,a}$ remains small enough (the Morrey-Campanato space is then more singular) the Besov regularity information is relevant, but as the parameter a increases (the Morrey-Campanato space becomes less singular) the Besov regularity information will be useless.

Theorem 2 (Morrey-Campanato and Besov competition) *Let $\theta_0 \in L^p \cap L^\infty(\mathbb{R}^n)$, with $n \geq 2$, be an initial data with $n(n-1) \vee 2n < p < +\infty$ and consider the nonlinear equation (2.5). Assume the following points*

- 1) \mathcal{L}^α is a Lévy-type operator of the form (2.1) satisfying hypothesis (2.2) with a smoothness degree

α such that

$$1 < \alpha = \frac{p+n}{p+1} < 2.$$

- 2) The operator $A_{[\theta]}$ that defines the nonlinear drift in equation (2.11) above is
 (a₂) bounded in $L^p - M^{p,a}$ spaces in the following sense

$$\|A_{[\theta]}\|_{L^\infty(M^{p,a})} \leq C_A \|\theta\|_{L^\infty(L^p)} \quad (0 \leq a < n), \quad (2.9)$$

(b₂) bounded in Besov spaces

$$\|A_{[\theta]}\|_{L^p(\dot{B}_p^{\frac{\alpha}{p},p})} \leq D_A \|\theta\|_{L^p(\dot{B}_p^{\frac{\alpha}{p},p})}.$$

Then, as long as we have the following condition between the Morrey-Campanato parameter a , the regularity degree α and the Lebesgue index p of the initial data:

$$0 \leq a < \alpha = \frac{p+n}{p+1}, \quad (2.10)$$

the solution $\theta(t, \cdot)$ of the equation (2.5) belongs to a Hölder space $\mathcal{C}^\gamma(\mathbb{R}^n)$ for $0 < \gamma < \frac{1}{4}$ small and moreover this value of α satisfies $1 < \alpha < \alpha_0 < 2$ and we break down the relationship (1.2).

However, if we have

$$a \geq \alpha = \frac{p+n}{p+1},$$

then the solution $\theta(t, \cdot)$ of the equation (2.5) still belongs to a Hölder space $\mathcal{C}^\gamma(\mathbb{R}^n)$ for $0 < \gamma < \frac{1}{4}$ small, but we have now $1 < \alpha_0 \leq \alpha < 2$: the Besov regularity information is useless and we do not break down the relationship (1.2).

We make here some remarks and comments.

- As for Theorem 1, the lower bound $n(n-1) \vee 2n < p$ is technical.
- If $0 \leq a < \alpha = \frac{p+n}{p+1}$, then it is easy to see that the parameters a, q, n and α do not fulfill equation (1.2) and that we have $1 < \alpha < \alpha_0 < 2$.
- Morrey-Campanato spaces $M^{p,a}$ become more and more regular as the value of the parameter a grows (recall Remark 2.1). The smallness condition $0 \leq a < \alpha$ stated in Theorem 2 reflects the fact that the Besov stability will help us only in very singular situations.
- In particular, due to homogeneity arguments, if $\alpha < a < n+p$, the Besov stability is useless if we compare it to the Morrey-Campanato norm control given by the hypothesis (2.9). Indeed, in this case the smaller smoothness degree for Lévy operators will be given by the relationship (1.2) instead of (2.10): this fact shows that condition (2.9) implies regularization properties for the nonlinear drift $A_{[\theta]}$. See [21] and the reference there in for a characterization of operators fulfilling this type of boundedness conditions.
- In the limit case when $a = \alpha = \frac{p+n}{p+1}$, then a Morrey-Campanato control and Besov stability provides the same regularity information: Besov finally meets Morrey-Campanato.

As we can observe from Theorems 1 and 2, the additional Besov regularity information allows us to break down to some extent the relationship (1.2) and we can consider lower regularity degrees for the Lévy-type operators, but only in the range $1 < \alpha < 2$, and this extra regularity is not strong enough to obtain results in the range $0 < \alpha \leq 1$.

This last case is particularly of interest when investigating the supercritical SQG equation, i.e. for $0 < \alpha < 1$. For the critical value $\alpha = 1$, from the seminal work of Caffarelli and Vasseur [3] we recall that if the initial data belongs to L^2 , an L^∞ control holds for the solution. It is then known that the drift based on the Riesz transform belongs to BMO . This allows to derive, either by De Giorgi like techniques in [3] or through the molecular like decomposition, see e.g. [17], [6], the Hölder continuity of the solution. However, when $0 < \alpha < 1$ by the homogeneity condition (1.2), to derive the Hölder continuity of the solution would require to establish some $(1 - \alpha)$ -Hölder regularity properties on the drift, see [10] and [11]. This is a very challenging open problem as we do not know if the drift of the SQG equation given in terms of Riesz transforms can be related (due to some cancellation property or to an extra hidden regularity property) to any kind of regularity. Therefore, a natural approach consists in considering a regularized drift. This has been done for instance in [13] for the linear case. We consider below a regularized drift and discuss how to use the Besov information to break the expected homogeneity. As explained in the introduction, our approach has some interest if $\theta_0 \in L^p, p < +\infty$.

In order to investigate this situation and to obtain a better understanding of the Morrey-Campanato/Besov competition we state now our two last results which are variations of Theorem 1 and Theorem 2. We will first introduce in Theorem 3 below a regularization in the nonlinear drift by considering $A_{[(-\Delta)^{-\frac{\eta}{2}}\theta]}$ where $0 < \eta < 1$ is a small fixed parameter.

Theorem 3 (Regular Drift) *Let $\theta_0 \in L^p \cap L^\infty(\mathbb{R}^n)$ be an initial data with $n(n-1) \vee 2n < p < +\infty$, let $0 < \eta < 1$ be a fixed (small) parameter and consider the nonlinear equation*

$$\begin{cases} \partial_t \theta(t, x) - \nabla \cdot (A_{[(-\Delta)^{-\frac{\eta}{2}}\theta]} \theta)(t, x) + \mathcal{L}^\alpha \theta(t, x) = 0, \\ \theta(0, x) = \theta_0(x). \end{cases} \quad (2.11)$$

Assume the following points

- 1) \mathcal{L}^α is a Lévy-type operator of the form (2.1) satisfying hypothesis (2.2) with a smoothness degree α such that

$$1/2 < \alpha = \frac{n + p(1 - \eta)}{p + 1} < 2. \quad (2.12)$$

- 2) The operator $A_{[(-\Delta)^{-\frac{\eta}{2}}\theta]}$ that defines the nonlinear drift in equation (2.11) above (a₃) is bounded in Morrey-Campanato spaces

$$\|A_{[(-\Delta)^{-\frac{\eta}{2}}\theta]}\|_{L^\infty(M^{q,a})} \leq C_A \|(-\Delta)^{-\frac{\eta}{2}}\theta\|_{L^\infty(M^{q,a})} \quad (0 \leq a < n), \quad (2.13)$$

- (b₃) is bounded in Besov spaces $\|A_{[(-\Delta)^{-\frac{\eta}{2}}\theta]}\|_{L^p(\dot{B}_p^{\alpha/p+\eta,p})} \leq D_A \|(-\Delta)^{-\frac{\eta}{2}}\theta\|_{L^p(\dot{B}_p^{\alpha/p+\eta,p})}$ with $0 < \alpha < 2$.

Then if $0 < \frac{\alpha}{p} + \eta < 1$ and if the parameters $p, q \geq 2n, a$ and η satisfy the identity

$$p = \frac{qn}{q\eta + n - a}, \quad (2.14)$$

we have that the solution $\theta(t, \cdot)$ belongs to a Hölder space $C^\gamma(\mathbb{R}^n)$ for $0 < \gamma < \frac{1}{4}$ small.

Just as in the two previous theorems, we have at our disposal two types of information. On the one hand, we have a general Morrey-Campanato boundedness property that reads as follows in this setting:

$$\begin{aligned} \|A_{[(-\Delta)^{-\frac{\eta}{2}}\theta]}\|_{L^\infty(M^{q,a})} &\leq C_A \|(-\Delta)^{-\frac{\eta}{2}}\theta\|_{L^\infty(M^{q,a})} \leq C_A \|(-\Delta)^{-\frac{\eta}{2}}\theta\|_{L^\infty(L^r)} \\ &\leq C_A \|\theta\|_{L^\infty(L^p)}, \end{aligned} \quad (2.15)$$

where we used the Morrey-Campanato-Lebesgue embedding (2.3) setting $r = \frac{qn}{n-a}$ and the Hardy-Littlewood-Sobolev inequality $\|(-\Delta)^{-\frac{\eta}{2}}\theta\|_{L^\infty(L^\sigma)} \leq c\|\theta\|_{L^\infty(L^p)}$, $\sigma = \frac{pn}{n-\eta p}$. Solving $\sigma = r$ yields relationship (2.14). Within this framework, applying the previous general results of [7], the corresponding smoothness degree α_0 is given by the relationship (1.2) and satisfies $1 < \alpha_0 < 2$. Note in particular that inequality (2.13) does not convey any regularity property.

On the other hand, we have a Besov control and using the nonlinearity of the drift we can see from (2.12) that we obtain a stronger smoothness degree α : indeed the fact that $\alpha < 1$ is equivalent to $\frac{n-1}{p} < \eta$, and this is possible if the parameter p is big enough. This situation is to be expected as we introduced the regularizing term $(-\Delta)^{-\frac{\eta}{2}}$, note however that if $\eta \rightarrow 0$ we recover Theorem 1. Moreover, just as in the previous Theorem 1, if $p \rightarrow +\infty$ we will lose all the Besov information and we will have $\alpha \rightarrow 1$. We emphasize as well that, even if we consider a *regularized* information as argument of the non linear operator $A_{[(-\Delta)^{-\frac{\eta}{2}}\theta]}$, we keep some kind of *homogeneity* property imposing a more stringent integrability condition assuming boundedness in $L^p(\dot{B}_p^{\alpha/p+\eta,p})$.

Finally, in our last theorem we consider a more irregular nonlinear drift in the following way $A_{[(-\Delta)^{\frac{\eta}{2}}\theta]}$ for $0 < \eta < 1$ and we will investigate the corresponding regularity degree α . Such type of singularizations have been considered as well in [4].

Theorem 4 (Singular Drift) *Let $\theta_0 \in L^p \cap L^\infty(\mathbb{R}^n)$ be an initial data with $n(n-1) \vee 2n < p < +\infty$, let $0 < \eta < \frac{1}{2(n-1)}$ be a fixed (small) parameter and consider the nonlinear equation*

$$\begin{cases} \partial_t \theta(t, x) - \nabla \cdot (A_{[(-\Delta)^{\frac{\eta}{2}}\theta]} \theta)(t, x) + \mathcal{L}^\alpha \theta(t, x) = 0, \\ \theta(0, x) = \theta_0(x). \end{cases} \quad (2.16)$$

Assume the following points

- 1) \mathcal{L}^α is a Lévy-type operator of the form (2.1) satisfying hypothesis (2.2) with a smoothness degree α such that

$$1 < \alpha = \frac{n + p(1 + \eta)}{p + 1} < 2. \quad (2.17)$$

- 2) The operator $A_{[(-\Delta)^{\frac{\eta}{2}}\theta]}$ that defines the nonlinear drift in equation (2.16) above

(a₄) is bounded in Morrey-Campanato spaces

$$\|A_{[(-\Delta)^{\frac{\eta}{2}}\theta]}\|_{L^\infty(M^{p,a})} \leq C_A \|\theta\|_{L^\infty(L^p)} \quad (0 \leq a < n), \quad (2.18)$$

(b₄) is bounded in Besov spaces $\|A_{[(-\Delta)^{\frac{\eta}{2}}\theta]}\|_{L^p(\dot{B}_p^{\alpha/p-\eta,p})} \leq D_A \|(-\Delta)^{\frac{\eta}{2}}\theta\|_{L^p(\dot{B}_p^{\alpha/p-\eta,p})}$.

Then if $0 < \frac{\alpha}{p} - \eta < 1$, as long as we have the following condition between the Morrey-Campanato parameter a , the regularity degree α and the Lebesgue index p of the initial data:

$$0 \leq a < \frac{n + p(1 - p\eta)}{p + 1} \quad (2.19)$$

the solution $\theta(t, \cdot)$ of the equation (2.16) belongs to a Hölder space $\mathcal{C}^\gamma(\mathbb{R}^n)$ for $0 < \gamma < \frac{1}{4}$ small and moreover this value of α satisfies $1 < \alpha < \alpha_0 < 2$ and we break down the relationship (1.2).

However, if we have

$$a \geq \frac{n + p(1 - p\eta)}{p + 1},$$

then the solution $\theta(t, \cdot)$ of the equation (2.16) still belongs to a Hölder space $\mathcal{C}^\gamma(\mathbb{R}^n)$ for $0 < \gamma < \frac{1}{4}$ small, but we have now $1 < \alpha_0 \leq \alpha < 2$: the Besov regularity information is useless and we do not break down the relationship (1.2).

This last theorem is very close to Theorem 2, indeed if $\eta \rightarrow 0$ we recover the results stated there.

We remark that the presence of the operator $(-\Delta)^{\frac{\eta}{2}}$ introduces (as expected) an even more singular behavior and this can be observed if we compare the condition (2.10) with (2.19). In this setting the Besov information is relevant only if the Morrey-Campanato space is quite singular and the threshold for the Morrey-Campanato regularity given by identity $a = \frac{n+p(1-p\eta)}{p+1}$ is indeed lower than the one stated in Theorem 2. Observe as well that, since we singularize the drift, we cannot rely anymore on the Hardy-Littlewood Sobolev inequality as in Theorem 3 (see estimates (2.15)). This induces to consider a stronger boundedness condition in (a_4) . Similarly, since $A_{[(\Delta)^{\frac{\eta}{2}}\theta]}$ is more singular, we alleviate the integrability constraint in (b_4) considering boundedness in $L^p(\dot{B}_p^{\alpha/p-\eta,p})$.

With Theorems 1-4 we show how to exploit, from different points of view and in a nonlinear setting, the additional Besov regularity information given by the general formula (1.6). As expected, this information allows us to improve previous results but it probably seems that the Besov control is too weak to enhance the situation when Morrey-Campanato convey regular properties.

Remark 2.2 *Although the hypotheses over the Morrey-Campanato norm differ from Theorem 1 to Theorem 4, the Besov control stated in terms of the space $\dot{B}_p^{\alpha/p,p}$ is essentially the same in all these theorems. This will allow us to give a general treatment for these theorems.*

3 Existence, maximum principle and other properties.

In this section we state results that are needed in order to perform the computations of the following sections. Some of these properties are well known and rather classical, moreover many of these details were already treated in [7] but, for the sake of completeness, we will explain here some computations, especially where we need to deal with the nonlinear drift and the different hypotheses used in the theorems stated in the section above.

- (i) **Existence.** We start studying existence for weak solutions of equation (2.5) with initial data $\theta_0 \in L^p \cap L^\infty(\mathbb{R}^n)$ where $n(n-1) \vee 2n < p < +\infty$. For this we introduce a regularization and using suitable controls we will pass to the limit to obtain weak solutions. Thus, for $\varepsilon > 0$, we consider the following problem

$$\begin{cases} \partial_t \theta(t, x) - \nabla \cdot (A_{[\theta]}^\varepsilon \theta)(t, x) + \mathcal{L}^\alpha \theta(t, x) = \varepsilon \Delta \theta(t, x), & t \in [0, T], \\ \theta(0, x) = \theta_0(x). \end{cases} \quad (3.1)$$

To obtain regularity in the time variable, we introduce $A_{[\theta]}^{*,\varepsilon} = A_{[\theta]} \star \psi_\varepsilon$ where \star stands for the time convolution and $\psi_\varepsilon(t) = \varepsilon^{-1} \psi(t/\varepsilon)$ where $\psi \in \mathcal{C}_0^\infty(\mathbb{R})$ is a non-negative function such that $\text{supp}(\psi) \subset B(0, 1)$ and $\int_{\mathbb{R}} \psi(t) dt = 1$. In the previous time convolution, we have extended the velocity field (in the time variable) on \mathbb{R} setting for all $s \in \mathbb{R} \setminus [0, T]$, $A_{[\theta]}(s, \cdot) = 0$. Then we define $A_{[\theta]}^\varepsilon = A_{[\theta]}^{*,\varepsilon} * \omega_\varepsilon$, here $*$ stands now for the spatial convolution and ω_ε is a usual mollifying kernel, i.e. $\omega_\varepsilon(x) = \varepsilon^{-n} \omega(x/\varepsilon)$, $\omega \in \mathcal{C}_0^\infty(\mathbb{R}^n)$ is a non-negative function such that

$\text{supp}(\omega) \subset B(0, 1)$ and $\int_{\mathbb{R}^n} \omega(x) dx = 1$. From this regularization, for a fixed $\varepsilon > 0$, the approximate drift $A_{[\theta]}^\varepsilon$ will be a smooth (in the time and space variables), divergence free vector field.

Since we can apply this approximation procedure in a completely similar manner to the drifts $A_{[(-\Delta)^{-\frac{\alpha}{2}}\theta]}$ and $A_{[(-\Delta)^{\frac{\alpha}{2}}\theta]}$ used in Theorems 3 and 4 respectively, we will continue our study by considering the problem (3.1) which corresponds to the setting of Theorems 1 and 2.

The problem (3.1) can thus be rewritten in the following way:

$$\theta(t, x) = e^{\varepsilon t \Delta} \theta_0(x) + \int_0^t e^{\varepsilon(t-s)\Delta} \nabla \cdot (A_{[\theta]}^\varepsilon \theta)(s, x) ds - \int_0^t e^{\varepsilon(t-s)\Delta} \mathcal{L}^\alpha \theta(s, x) ds,$$

and, in order to construct solutions, we will apply the Banach contraction scheme in the space $L^\infty([0, T], L^p(\mathbb{R}^n))$ with the norm $\|\theta\|_{L^\infty(L^p)} = \sup_{t \in [0, T]} \|\theta(t, \cdot)\|_{L^p}$. Following [7] we have the estimates

$$\begin{aligned} \|e^{\varepsilon t \Delta} \theta_0\|_{L^\infty(L^p)} &\leq \|\theta_0\|_{L^p} \quad \text{and} \\ \left\| \int_0^t e^{\varepsilon(t-s)\Delta} \mathcal{L}^\alpha \theta(s, x) ds \right\|_{L^\infty(L^p)} &\leq C \left(\frac{T^{1-\frac{\alpha}{2}}}{\varepsilon^{\frac{\alpha}{2}}} + \frac{T^{1-\frac{\delta}{2}}}{\varepsilon^{\frac{\delta}{2}}} \right) \|\theta\|_{L^\infty(L^p)}, \end{aligned} \quad (3.2)$$

where we recall from (2.2) that the exponent δ is related to the tail behavior of the operator \mathcal{L}^α .

Thus, we only need to treat the bilinear quantity

$$B(\theta, \varphi) = \int_0^t e^{\varepsilon(t-s)\Delta} \nabla \cdot (A_{[\theta]}^\varepsilon \varphi)(s, x) ds,$$

and we have

$$\begin{aligned} \|B(\theta, \varphi)\|_{L^\infty(L^p)} &= \sup_{0 < t < T'} \left\| \int_0^t e^{\varepsilon(t-s)\Delta} \nabla \cdot (A_{[\theta]}^\varepsilon \varphi)(s, \cdot) ds \right\|_{L^p} \\ &= \sup_{0 < t < T'} \left\| \int_0^t \nabla \cdot (A_{[\theta]}^\varepsilon \varphi) * h_{\varepsilon(t-s)}(s, \cdot) ds \right\|_{L^p} \\ &\leq \sup_{0 < t < T'} \int_0^t \|(A_{[\theta]}^\varepsilon \varphi)(s, \cdot)\|_{L^p} \|\nabla h_{\varepsilon(t-s)}\|_{L^1} ds \\ &\leq \sup_{0 < t < T'} \int_0^t \|A_{[\theta]}^\varepsilon(s, \cdot)\|_{L^\infty} \|\varphi(s, \cdot)\|_{L^p} C(\varepsilon(t-s))^{-1/2} ds. \end{aligned} \quad (3.3)$$

The computations performed until now (*i.e.* from (3.1) to (3.3)) are common to Theorems 1-4 and we will continue the proof of the existence under the hypotheses of Theorem 1: the modifications for Theorems 2, 3 and 4 are given in Remark 3.1 below.

At this point we use the following inequality

$$\|A_{[\theta]}^\varepsilon\|_{L^\infty(L^\infty)} \leq C \varepsilon^{-n/q} \|A_{[\theta]}\|_{L^\infty(M^{q,a})}, \quad (3.4)$$

valid for $1 < q < +\infty$ and which is proven in the Lemma A-1 of [7] (for functions in $M^{q,a}$) to obtain

$$\begin{aligned} \|B(\theta, \varphi)\|_{L^\infty(L^p)} &\leq C \varepsilon^{-n/q} \|A_{[\theta]}\|_{L^\infty(M^{q,a})} \|\varphi\|_{L^\infty(L^p)} \sup_{0 < t < T'} \int_0^t C(\varepsilon(t-s))^{-1/2} ds \\ &\leq C \frac{T^{\frac{1}{2}}}{\varepsilon^{\frac{1}{2}}} \varepsilon^{-n/q} \|A_{[\theta]}\|_{L^\infty(M^{q,a})} \|\varphi\|_{L^\infty(L^p)}. \end{aligned}$$

We use now hypothesis (2.6) stated in Theorem 1 (*i.e.* $\|A_{[\theta]}\|_{L^\infty(M^{q,a})} \leq C_A \|\theta\|_{L^\infty(M^{q,a})}$) and we have

$$\|B(\theta, \varphi)\|_{L^\infty(L^p)} \leq C_A \frac{T^{\frac{1}{2}}}{\varepsilon^{\frac{1}{2}}} \varepsilon^{-n/q} \|\theta\|_{L^\infty(M^{q,a})} \|\varphi\|_{L^\infty(L^p)}, \quad (3.5)$$

but, since by the relationship (2.8) we have the identity $p = \frac{qn}{n-a}$, we use the embedding (2.3) to write $\|\theta\|_{L^\infty(M^{q,a})} \leq \|\theta\|_{L^\infty(L^p)}$, from which we deduce the continuity of the bilinear form $B(\theta, \varphi)$:

$$\|B(\theta, \varphi)\|_{L^\infty(L^p)} \leq C_A \frac{T^{\frac{1}{2}}}{\varepsilon^{\frac{1}{2}}} \varepsilon^{-n/q} \|\theta\|_{L^\infty(L^p)} \|\varphi\|_{L^\infty(L^p)}. \quad (3.6)$$

Now, with inequalities (3.2) and (3.6), it is easy to obtain the existence of solutions for the regularized problem (3.1) in a small time interval.

Remark 3.1 (Existence for Theorems 2, 3 & 4)

- To prove the existence of solutions for the problem (3.1) under the hypotheses stated in Theorem 2, we only need to study inequality (3.3) and for this we use the general estimate (3.4) in the following manner $\left\|A_{[\theta]}^\varepsilon(s, \cdot)\right\|_{L^\infty(L^\infty)} \leq C\varepsilon^{-n/p} \|A_{[\theta]}\|_{L^\infty(M^{p,a})}$, thus, applying the hypothesis (2.9) we obtain the following inequality

$$\|B(\theta, \varphi)\|_{L^\infty(L^p)} \leq C_A \frac{T^{\frac{1}{2}}}{\varepsilon^{\frac{1}{2}}} \varepsilon^{-n/p} \|\theta\|_{L^\infty(L^p)} \|\varphi\|_{L^\infty(L^p)},$$

from which we deduce the continuity of the bilinear form.

- For the existence of solutions for equation (3.1) within the framework of Theorem 3 we start from expression (3.3) and we have

$$\|B(\theta, \varphi)\|_{L^\infty(L^p)} \leq \sup_{0 < t < T'} \int_0^t \left\|A_{[(-\Delta)^{-\frac{n}{2}\theta]}^\varepsilon(s, \cdot)\right\|_{L^\infty} \|\varphi(s, \cdot)\|_{L^p} C(\varepsilon(t-s))^{-1/2} ds,$$

thus using inequality (3.4) we obtain the continuity of this bilinear form:

$$\begin{aligned} \|B(\theta, \varphi)\|_{L^\infty(L^p)} &\leq C \frac{T^{\frac{1}{2}}}{\varepsilon^{\frac{1}{2}}} \varepsilon^{-n/q} \|A_{[(-\Delta)^{-\frac{n}{2}\theta]}\|_{L^\infty(M^{q,a})} \|\varphi\|_{L^\infty(L^p)} \\ &\leq C_A \frac{T^{\frac{1}{2}}}{\varepsilon^{\frac{1}{2}}} \varepsilon^{-n/q} \|\theta\|_{L^\infty(L^p)} \|\varphi\|_{L^\infty(L^p)}, \end{aligned}$$

where we used (2.15) for the last inequality.

- Finally, for Theorem 4, from expression (3.3) we have

$$\|B(\theta, \varphi)\|_{L^\infty(L^p)} \leq \sup_{0 < t < T'} \int_0^t \left\|A_{[(-\Delta)^{\frac{n}{2}\theta]}^\varepsilon(s, \cdot)\right\|_{L^\infty} \|\varphi(s, \cdot)\|_{L^p} C(\varepsilon(t-s))^{-1/2} ds,$$

applying the general inequality (3.4) we obtain

$$\left\|A_{[(-\Delta)^{\frac{n}{2}\theta]}^\varepsilon(s, \cdot)\right\|_{L^\infty(L^\infty)} \leq C\varepsilon^{-n/p} \|A_{[(-\Delta)^{\frac{n}{2}\theta]}\|_{L^\infty(M^{p,a})},$$

and with the hypothesis (2.18) we write

$$\begin{aligned} \|B(\theta, \varphi)\|_{L^\infty(L^p)} &\leq C \frac{T^{\frac{1}{2}}}{\varepsilon^{\frac{1}{2}}} \varepsilon^{-n/p} \|A_{[(-\Delta)^{\frac{n}{2}\theta]}\|_{L^\infty(M^{p,a})} \|\varphi\|_{L^\infty(L^p)} \\ &\leq C_A \frac{T^{\frac{1}{2}}}{\varepsilon^{\frac{1}{2}}} \varepsilon^{-n/p} \|\theta\|_{L^\infty(L^p)} \|\varphi\|_{L^\infty(L^p)}. \end{aligned}$$

(ii) **Regularity.** We now study the regularity of the solutions constructed by this method. And we will see that solutions of the approximated problem (3.1) are actually smooth. Indeed, following [7], we will work in the time interval $0 < T_0 < T_* < t < T^*$ where T_0 , T_* and T^* are fixed bounds and by iteration we will prove that $\theta \in \bigcap_{0 < T_0 < T_* < t < T^*} L^\infty([0, t], W^{\frac{k}{2}, p}(\mathbb{R}^n))$

for all $k \in \mathbb{N}$ where we define the Sobolev space $W^{s, p}(\mathbb{R}^n)$ for $s \in \mathbb{R}$ and $1 < p < +\infty$ by $\|f\|_{W^{s, p}} = \|f\|_{L^p} + \|(-\Delta)^{\frac{s}{2}} f\|_{L^p}$. Note that this is true for $k = 0$. So let us assume that it is also true for $k > 0$ and we will show that it is still true for $k + 1$.

We will work under the framework given in Theorem 1, modifications for Theorems 2-4 are straightforward using the computations made in Remark 3.1.

We thus consider then the next problem

$$\theta(t, x) = e^{\varepsilon(t-T_0)\Delta} \theta(T_0, x) + \int_{T_0}^t e^{\varepsilon(t-s)\Delta} \nabla \cdot (A_{[\theta]}^\varepsilon \theta)(s, x) ds - \int_{T_0}^t e^{\varepsilon(t-s)\Delta} \mathcal{L}^\alpha \theta(s, x) ds,$$

and we have the following estimate

$$\begin{aligned} \|\theta\|_{L^\infty(W^{\frac{k+1}{2}, p})} &\leq \|e^{\varepsilon(t-T_0)\Delta} \theta(T_0, \cdot)\|_{L^\infty(W^{\frac{k+1}{2}, p})} \\ &\quad + \left\| \int_{T_0}^t e^{\varepsilon(t-s)\Delta} \nabla \cdot (A_{[\theta]}^\varepsilon \theta)(s, \cdot) ds \right\|_{L^\infty(W^{\frac{k+1}{2}, p})} \\ &\quad + \left\| \int_{T_0}^t e^{\varepsilon(t-s)\Delta} \mathcal{L}^\alpha \theta(s, \cdot) ds \right\|_{L^\infty(W^{\frac{k+1}{2}, p})}. \end{aligned} \quad (3.7)$$

The first and the last term of (3.7) were already treated in [7], indeed we have

$$\begin{aligned} \|e^{\varepsilon(t-T_0)\Delta} \theta(T_0, \cdot)\|_{L^\infty(W^{\frac{k+1}{2}, p})} &\leq C \|\theta(T_0, \cdot)\|_{L^p} \max \left\{ 1; [\varepsilon(t-T_0)]^{-\frac{k+1}{4}} \right\} \quad \text{and} \\ \left\| \int_{T_0}^t e^{\varepsilon(t-s)\Delta} \mathcal{L}^\alpha \theta(s, \cdot) ds \right\|_{L^\infty(W^{\frac{k+1}{2}, p})} &\leq C \|\theta\|_{L^\infty(W^{\frac{k}{2}, p})} \\ &\quad \times \int_{T_0}^t \max \left\{ \left([\varepsilon(t-s)]^{-\frac{\alpha}{2}} + \varepsilon(t-s) \right)^{-\frac{\delta}{2}}; \left([\varepsilon(t-s)]^{-\frac{1+2\alpha}{4}} + [\varepsilon(t-s)]^{-\frac{1+2\delta}{4}} \right) \right\} ds. \end{aligned}$$

Thus we only study the second term of (3.7) and following the same ideas as in the existence computations performed above one has

$$\begin{aligned} I &= \left\| \int_{T_0}^t e^{\varepsilon(t-s)\Delta} \nabla \cdot (A_{[\theta]}^\varepsilon \theta)(s, \cdot) ds \right\|_{L^\infty(W^{\frac{k+1}{2}, p})} \leq C \|A_{[\theta]}\|_{L^\infty(M^{q, \alpha})} \|\theta\|_{L^\infty(W^{\frac{k}{2}, p})} \\ &\quad \times \sup \int_{T_0}^t (1 + \varepsilon^{-N}) \varepsilon^{-n/q} \max \left\{ [\varepsilon(t-s)]^{-\frac{1}{2}}; [\varepsilon(t-s)]^{-\frac{3}{4}} \right\} ds, \end{aligned} \quad (3.8)$$

for $N \geq \frac{k}{2}$. At this point we use the hypotheses of Theorem 1 (*i.e.* the Morrey-Campanato boundedness and the Morrey-Campanato-Lebesgue embedding) to write

$$\begin{aligned} I &\leq C_A \|\theta\|_{L^\infty(M^{q, \alpha})} \|\theta\|_{L^\infty(W^{\frac{k}{2}, p})} \\ &\quad \times \sup \int_{T_0}^t (1 + \varepsilon^{-N}) \varepsilon^{-n/q} \max \left\{ [\varepsilon(t-s)]^{-\frac{1}{2}}; [\varepsilon(t-s)]^{-\frac{3}{4}} \right\} ds \\ &\leq C_A \|\theta\|_{L^\infty(L^p)} \|\theta\|_{L^\infty(W^{\frac{k}{2}, p})} \\ &\quad \times \sup \int_{T_0}^t (1 + \varepsilon^{-N}) \varepsilon^{-n/q} \max \left\{ [\varepsilon(t-s)]^{-\frac{1}{2}}; [\varepsilon(t-s)]^{-\frac{3}{4}} \right\} ds. \end{aligned} \quad (3.9)$$

With these inequalities we conclude that the norm $\|\theta\|_{L^\infty(W^{\frac{k+1}{2},p})}$ is controlled for all $\varepsilon > 0$: we have proven spatial regularity. Time regularity inductively follows since we have for all $k \geq 0$:

$$\frac{\partial^{k+1}}{\partial t^{k+1}}\theta(t, x) - \nabla \cdot \left(\frac{\partial^k}{\partial t^k}(A_{[\theta]}^\varepsilon \theta) \right) (t, x) + \mathcal{L}^\alpha \left(\frac{\partial^k}{\partial t^k}\theta \right) (t, x) = \varepsilon \Delta \left(\frac{\partial^k}{\partial t^k}\theta \right) (t, x).$$

Regularity under the hypotheses of Theorems 2-4 follows essentially the same lines: apply Remark 3.1 to the computations performed in (3.8)-(3.9).

(iii) **Maximum principle.** Let $\theta_0 \in L^p(\mathbb{R}^n)$ with $n(n-1) \vee 2n < p < +\infty$ be an initial data, then the associated solution of the regularized problem (2.16) satisfies the following maximum principle for all $t \in [0, T]$:

$$\|\theta(t, \cdot)\|_{L^p} \leq \|\theta_0\|_{L^p}. \quad (3.10)$$

This maximum principle is a consequence of the divergence free property of the drift and of the following computations. Again, we assume the framework of Theorem 1 since the result for Theorems 2-4 is essentially the same. We write for $n(n-1) \vee 2n < p < +\infty$:

$$\begin{aligned} \frac{d}{dt}\|\theta(t, \cdot)\|_{L^p}^p &= p \int_{\mathbb{R}^n} |\theta|^{p-2}\theta \left(\varepsilon \Delta \theta + \nabla \cdot (A_{[\theta]}^\varepsilon \theta) - \mathcal{L}^\alpha \theta \right) (t, x) dx \\ &= p\varepsilon \int_{\mathbb{R}^n} |\theta|^{p-2}\theta \Delta \theta(t, x) dx - p \int_{\mathbb{R}^n} |\theta|^{p-1} \text{sgn}(\theta) \mathcal{L}^\alpha \theta(t, x) dx, \end{aligned}$$

where we used the fact that $\nabla \cdot (A_{[\theta]}^\varepsilon) = 0$. Thus, we have

$$\frac{d}{dt}\|\theta(t, \cdot)\|_{L^p}^p - p\varepsilon \int_{\mathbb{R}^n} |\theta|^{p-2}\theta \Delta \theta(t, x) dx + p \int_{\mathbb{R}^n} |\theta|^{p-1} \text{sgn}(\theta) \mathcal{L}^\alpha \theta(t, x) dx = 0,$$

and integrating in time we obtain

$$\begin{aligned} \|\theta(t, \cdot)\|_{L^p}^p - p\varepsilon \int_0^t \int_{\mathbb{R}^n} |\theta|^{p-2}\theta \Delta \theta(s, x) dx ds \\ + p \int_0^t \int_{\mathbb{R}^n} |\theta|^{p-1} \text{sgn}(\theta) \mathcal{L}^\alpha \theta(s, x) dx ds = \|\theta_0\|_{L^p}^p. \end{aligned} \quad (3.11)$$

To finish, we have that the quantities

$$-p\varepsilon \int_{\mathbb{R}^n} |\theta|^{p-2}\theta \Delta \theta(s, x) dx \quad \text{and} \quad p \int_0^t \int_{\mathbb{R}^n} |\theta|^{p-1} \text{sgn}(\theta) \mathcal{L}^\alpha \theta(s, x) dx ds$$

are both positive. We refer to the prof of Proposition 2.1 in [7] for details. Thus, getting back to (3.11), we have that all these quantities are bounded and positive and we obtain the maximum principle property stated in (3.10).

Remark 3.2 *With this a priori bound (3.10), it is possible to obtain global solutions $\theta(t, \cdot)$ where $t \in [0, T]$ and $0 < T < +\infty$ is a fixed final time.*

Remark 3.3 (Uniform controls) *Following the hypotheses stated in Theorems 1-4, this maximum principle implies a uniform control over the nonlinear drift.*

- for Theorem 1, using (2.6) and the Morrey-Campanato-Lebesgue embedding (2.3) we have

$$\|A_{[\theta]}\|_{L^\infty(M^{q,a})} \leq C_A \|\theta\|_{L^\infty(M^{q,a})} \leq C_A \|\theta\|_{L^\infty(L^p)} \leq C_A \|\theta_0\|_{L^p} < +\infty,$$

- for Theorem 2, using (2.9) we have

$$\|A_{[\theta]}\|_{L^\infty(M^{p,a})} \leq C_A \|\theta\|_{L^\infty(L^p)} \leq C_A \|\theta_0\|_{L^p} < +\infty,$$

- for Theorem 3, from (2.15),

$$\|A_{[(-\Delta)^{-\frac{\eta}{2}}\theta]}\|_{L^\infty(M^{q,a})} \leq C_A \|\theta\|_{L^\infty(L^p)} \leq C_A \|\theta_0\|_{L^p} < +\infty,$$

- finally, for Theorem 4, using (2.18) we have

$$\|A_{[(-\Delta)^{\frac{\eta}{2}}\theta]}\|_{L^\infty(M^{p,a})} \leq C_A \|\theta\|_{L^\infty(L^p)} \leq C_A \|\theta_0\|_{L^p} < +\infty.$$

(iv) **Besov Regularity.** This property is the crucial point of this article as it gives an additional information on weak solutions which was not exploited in [7] where we only considered linear equations. Thus, since we consider now a nonlinear drift that satisfies a Besov space stability property as stated in Theorems 1-4, it is interesting to investigate the behavior of weak solutions in terms of Besov spaces and to this end we have the following theorem from [5]:

Theorem 5 (Besov Regularity) *Let \mathcal{L}^α be a Lévy-type operator of the form (2.1) satisfying hypothesis (2.2) with $0 < \alpha < 2$. Let $2 \leq p < +\infty$ and let $f : \mathbb{R}^n \rightarrow \mathbb{R}$ be a function such that $f \in L^p(\mathbb{R}^n)$ and*

$$\int_{\mathbb{R}^n} |f(x)|^{p-2} f(x) \mathcal{L}^\alpha f(x) dx < +\infty, \quad \text{then} \quad f \in \dot{B}_p^{\frac{\alpha}{p}, p}(\mathbb{R}^n).$$

See [5] and [7] for a proof of this fact. Let us explain briefly how we will use this regularity property: combining this result and formula (3.11) we obtain the important estimate (1.6) which gives $\theta \in L^p([0, T], \dot{B}_p^{\frac{\alpha}{p}, p}) = L^p(\dot{B}_p^{\frac{\alpha}{p}, p})$ and therefore that for almost all $t \in [0, T]$, $\theta(t, \cdot) \in \dot{B}_p^{\frac{\alpha}{p}, p}$. Now, from the Besov stability hypothesis stated in Theorems 1-4 we have $\|A_{[\theta]}\|_{L^p(\dot{B}_p^{\frac{\alpha}{p}, p})} \leq D_A \|\theta\|_{L^p(\dot{B}_p^{\frac{\alpha}{p}, p})}$, which gives us a Besov control for the nonlinear drift:

$$\|A_{[\theta]}\|_{L^p(\dot{B}_p^{\frac{\alpha}{p}, p})} \leq D_A \|\theta\|_{L^p(\dot{B}_p^{\frac{\alpha}{p}, p})} \leq D_A \|\theta_0\|_{L^p} < +\infty. \quad (3.12)$$

(v) **The limit.** The previous solutions form a family of regular functions $(\theta^{(\varepsilon)})_{\varepsilon > 0} \in L^\infty([0, T], L^p(\mathbb{R}^n))$ which satisfy the uniform bound $\|\theta^{(\varepsilon)}(t, \cdot)\|_{L^p} \leq \|\theta_0\|_{L^p}$; in order to conclude we need to pass to the limit by letting $\varepsilon \rightarrow 0$. For this, since we have $\theta_0 \in L^p \cap L^\infty(\mathbb{R}^n)$ and since we have the uniform controls over the nonlinear drift given in Remark 3.3, we can apply the same arguments used in [7], we thus obtain existence and uniqueness of weak solutions for the equations stated in Theorems 1-4 with an initial data in $\theta_0 \in L^p(\mathbb{R}^n)$, $2n \leq p < +\infty$ that satisfy the maximum principle. Moreover, we have that these solutions $\theta(t, x)$ belong to the space $L^\infty([0, T], L^p(\mathbb{R}^n)) \cap L^p([0, T], \dot{B}_p^{\frac{\alpha}{p}, p}(\mathbb{R}^n))$.

Remark 3.4 *The hypothesis $\theta_0 \in L^\infty(\mathbb{R}^n)$ (and not only $\theta_0 \in L^p$) is useful in order to obtain general existence results when dealing with general drifts belonging to Morrey-Campanato spaces. See Theorem 1 of [7] for the details.*

4 Hölder Regularity and proof for Theorems 1-4

One important feature of Hardy spaces relies in the following property: let $\frac{n}{n+1} < \sigma < 1$ and fix $0 < \gamma = n(\frac{1}{\sigma} - 1) < 1$, then the dual of the local Hardy space $h^\sigma(\mathbb{R}^n)$ is the Hölder space² $C^\gamma(\mathbb{R}^n)$ and with the help of a dual equation we will use this property in order to study Hölder regularity of the solutions of equation (2.5).

We recall that the local Hardy space $h^\sigma(\mathbb{R}^n)$ with $0 < \sigma < 1$ is the set of distributions f that admits the decomposition $f = \sum_{j \in \mathbb{N}} \lambda_j \psi_j$, where $(\lambda_j)_{j \in \mathbb{N}}$ is a sequence of complex numbers such that

$\sum_{j \in \mathbb{N}} |\lambda_j|^\sigma < +\infty$ and $(\psi_j)_{j \in \mathbb{N}}$ is a family of molecules given by the following definition.

Definition 4.1 Set $\frac{n}{n+1} < \sigma < 1$, define $\gamma = n(\frac{1}{\sigma} - 1)$ and fix a real number ω such that $0 < \gamma < \omega < \frac{1}{4}$. For $0 < r < 1$ an integrable function ψ is an molecule if we have

$$\int_{\mathbb{R}^n} |\psi(x)| |x - x_0|^\omega dx \leq (\zeta r)^{\omega - \gamma}, \text{ for } x_0 \in \mathbb{R}^n, \quad \text{and} \quad \|\psi\|_{L^\infty} \leq \frac{1}{(\zeta r)^{n+\gamma}}, \quad (4.1)$$

$$\int_{\mathbb{R}^n} \psi(x) dx = 0. \quad (4.2)$$

In the above conditions the quantity $\zeta > 1$ denotes a constant that depends on γ, ω, α and other parameters to be specified later on. In the case when $1 \leq r < +\infty$, we only require conditions (4.1) for the molecule ψ while the moment condition (4.2) is dropped.

Remark 4.1 Conditions (4.1) imply the estimate $\|\psi\|_{L^1} \leq C(\zeta r)^{-\gamma}$. Thus, every molecule belongs to $L^p(\mathbb{R}^n)$ with $1 < p < +\infty$ since we have

$$\|\psi\|_{L^p} \leq C(\zeta r)^{-n + \frac{n}{p} - \gamma}. \quad (4.3)$$

Recall also that the Schwartz class $\mathcal{S}(\mathbb{R}^n)$ is dense in $h^\sigma(\mathbb{R}^n)$, this fact is of course very useful for approximation procedures.

See [7] for more remarks about this definition. See also [24], Chapter III, §5.7, [25], Chapter XIV, §6.6 or [17].

The dual equation

Once we have described the elements of the Hardy spaces, we need to derive a dual equation from the original problem (2.5), and for this we proceed as follows: assume that $\theta_0 \in L^p \cap L^\infty(\mathbb{R}^n)$ is an initial data and consider the equation (2.5) with a Lévy-type operator \mathcal{L}^α and a nonlinear drift $A_{[\theta]}$ satisfying all the hypotheses stated in Theorem 1 (since all the nonlinear drift in Theorems 2-4 are divergence free, the arguments are similar in these cases). By the previous sections we can construct on the interval $[0, T]$, with $0 < T < +\infty$ fixed, a corresponding weak solution $\theta(\cdot, \cdot) \in L^\infty([0, T], L^p(\mathbb{R}^n)) \cap L^p([0, T], \dot{B}_p^{\frac{\alpha}{p}, p}(\mathbb{R}^n))$ that satisfies the maximum principle from which we deduce the uniform bounds (recall Remark 3.3 and formula (3.12)):

$$\begin{aligned} \|A_{[\theta]}\|_{L^\infty(M^{q,a})} &< +\infty, \\ \|A_{[\theta]}\|_{L^p(\dot{B}_p^{\frac{\alpha}{p}, p})} &\leq D_A \|\theta\|_{L^p(\dot{B}_p^{\frac{\alpha}{p}, p})} \leq D_A \|\theta_0\|_{L^p} < +\infty. \end{aligned} \quad (4.4)$$

²See [15] for a proof of this fact and see [8] and [24] for a detailed treatment on Hardy spaces.

Fix now a time $0 < t < T$ and consider the following dual equation

$$\begin{cases} \partial_s \psi(s, x) = -\nabla \cdot [A_{[\theta]}(t-s, x)\psi(s, x)] - \mathcal{L}^\alpha \psi(s, x), & s \in [0, t], \\ \psi(0, x) = \psi_0(x) \in L^1 \cap L^\infty(\mathbb{R}^n), \end{cases} \quad (4.5)$$

where \mathcal{L}^α is a Lévy-type operator of degree $0 < \alpha < 2$ and the initial data ψ_0 is a molecule in the sense of Definition 4.1 above.

Note that this problem is now a *linear* equation since the drift $A_{[\theta]}$ does not depend on $\psi(t, x)$. Remark also that, by hypothesis we have $\operatorname{div}(A_{[\theta]}) = 0$ and from (4.4) we have a uniform control over $\|A_{[\theta]}\|_{L^\infty(M^{q,a})}$ and thus by [7] we obtain global existence and a L^p -maximum principle for the solutions $\psi(\cdot, \cdot)$ of such equation.

Once we have the dual equation and the corresponding solution ψ , we can state the following theorem which will help us to prove Theorems 1-4 using the Hardy-Hölder duality.

Theorem 6 (Transfer Property) *Let $\theta_0 \in L^p \cap L^\infty(\mathbb{R}^n)$ and let $\theta(t, x)$ be a weak solution of the equation (2.5) in the interval $[0, T]$ where the nonlinear drift and the Lévy-type operator \mathcal{L}^α satisfy the hypotheses of Theorems 1-4. Let $t \in [0, T]$ and let $\psi(s, x)$ be a solution of the backward problem (4.5) for $s \in [0, t]$. Then we have the identity*

$$\int_{\mathbb{R}^n} \theta(t, x)\psi(0, x)dx = \int_{\mathbb{R}^n} \theta\left(\frac{t}{2}, x\right)\psi\left(\frac{t}{2}, x\right)dx.$$

Proof. We first consider the expression

$$\partial_s \int_{\mathbb{R}^n} \theta(t-s, x)\psi(s, x)dx = \int_{\mathbb{R}^n} -\partial_t \theta(t-s, x)\psi(s, x) + \partial_s \psi(s, x)\theta(t-s, x)dx.$$

Using equations (2.5) and (4.5) we obtain

$$\begin{aligned} \partial_s \int_{\mathbb{R}^n} \theta(t-s, x)\psi(s, x)dx &= \int_{\mathbb{R}^n} \left\{ -\nabla \cdot [(A_{[\theta]}(t-s, x)\theta(t-s, x)]\psi(s, x) + \mathcal{L}^\alpha \theta(t-s, x)\psi(s, x) \right. \\ &\quad \left. -\nabla \cdot [(A_{[\theta]}(t-s, x)\psi(s, x))]\theta(t-s, x) - \mathcal{L}^\alpha \psi(s, x)\theta(t-s, x) \right\} dx. \end{aligned}$$

Now, by an integration by parts in the first term of the right-hand side of the previous formula, using the fact that $A_{[\theta]}$ is divergence free and the symmetry of the operator \mathcal{L}^α we have that the expression above is equal to zero, so the quantity $\int_{\mathbb{R}^n} \theta(t-s, x)\psi(s, x)dx$, remains constant in time. We only have to set $s = 0$ and $s = \frac{t}{2}$.

Since the drifts $A_{[(-\Delta)^{-\frac{\gamma}{2}}\theta]}$ and $A_{[(-\Delta)^{\frac{\gamma}{2}}\theta]}$ used in Theorems 3 and 4 are divergence free, the proof follows the same lines for these cases. ■

This result is borrowed from [17] and was used in [7], but we have made here a slight modification which is crucial in this article. Indeed, in those previous articles, Theorem 6 was used to replace the Hölder-Hardy duality bracket $\langle \theta(t, \cdot), \psi_0 \rangle_{\mathcal{C}^\lambda \times h^\sigma}$ into a simpler $L^\infty - L^1$ bracket $\langle \theta_0, \psi(t, \cdot) \rangle_{L^\infty \times L^1}$ (the

initial data θ_0 was assumed in L^∞), and then the proof of the Hölder regularity was reduced to a suitable L^1 control for deformed molecules $\psi(t, \cdot)$ since

$$|\langle \theta_0, \psi(t, \cdot) \rangle_{L^\infty \times L^1}| \leq \|\theta_0\|_{L^\infty} \|\psi(t, \cdot)\|_{L^1}.$$

Now, with this previous theorem, we replace the bracket $\langle \theta(t, \cdot), \psi_0 \rangle_{C^\lambda \times h^\sigma}$ by $\langle \theta(t/2, \cdot), \psi(t/2, \cdot) \rangle_{L^p \times L^{p'}}$ where $\frac{1}{p} + \frac{1}{p'} = 1$ and this bracket in time $t/2$ gives us *more* information than $\langle \theta_0, \psi(t, \cdot) \rangle_{L^p \times L^{p'}}$ and the modification is not only related to the L^p setting.

Indeed, by the maximum principle we have at time $t/2$ the inequalities

$$|\langle \theta(t/2, \cdot), \psi(t/2, \cdot) \rangle_{L^p \times L^{p'}}| \leq \|\theta(t/2, \cdot)\|_{L^p} \|\psi(t/2, \cdot)\|_{L^{p'}} \leq \|\theta_0\|_{L^p} \|\psi(t/2, \cdot)\|_{L^{p'}}, \quad (4.6)$$

thus we only need to control the $L^{p'}$ -behavior of $\psi(t/2, \cdot)$.

But, at time $t/2$ we have $\theta \in L^\infty(L^p) \cap L^p([0, T], \dot{B}_p^{\frac{\alpha}{p}, p})$ from which we deduce the uniform controls given in expression (4.4) for the drift: in particular at time $t/2$, due to the boundedness properties of the drift $A_{[\theta]}$ we have a Besov control for the velocity field which *was not available* at time $t = 0$ and this additional information is the key of our computations. This is a specificity of the nonlinear case.

Remark 4.2 *Note that the Besov control hypothesis is the same for Theorems 1-4 and what really changes from one theorem to another is the Morrey-Campanato boundedness properties. Since we have in these cases the uniform controls stated in Remark 3.3, the corresponding smoothness degree α_0 is directly given by the relationship (1.2). We thus only have to study how to use the Besov information to obtain a new smoothness degree α in order to establish the comparison between the Besov and the Morrey-Campanato regularity.*

Proof of Theorem 1. From the transfer property given in Theorem 6 and with the inequalities (4.6) we only need to study the control of the $L^{p'}$ norm of $\psi(t, \cdot)$ and due to the maximum principle we can divide our proof into two steps following the molecule's size. Indeed, if $r \geq 1$ we have

$$\|\theta_0\|_{L^p} \|\psi(t/2, \cdot)\|_{L^{p'}} \leq \|\theta_0\|_{L^p} \|\psi_0\|_{L^{p'}} \leq Cr^{-n+\frac{n}{p'}-\gamma} \|\theta_0\|_{L^p},$$

but, since $r \geq 1$, we obtain $|\langle \theta(t, \cdot), \psi_0 \rangle_{C^\gamma \times h^\sigma}| < +\infty$ for all big molecules.

It remains to treat the $L^{p'}$ control for *small* molecules and this is done in the following theorem:

Theorem 7 *Let ψ_0 be a small molecule and consider $\psi(t/2, \cdot)$ the associated solution of the backward problem (4.5). If we assume moreover $n(n-1) \vee 2n < p < +\infty$, then there exists $C > 0$ such that for a given time $0 < T_0 < t/2$ we have the following control of the $L^{p'}$ -norm.*

$$\|\psi(t/2, \cdot)\|_{L^{p'}} \leq CT_0^{-n+\frac{n}{p'}-\gamma} \quad (T_0 < t/2 < T),$$

where $0 < \gamma < \frac{1}{4}$.

Accepting for a while this result, we have then a good control over the quantity $\|\psi(t/2, \cdot)\|_{L^{p'}}$ for all $0 < r < 1$ and getting back to (4.6) we obtain that $|\langle \theta(t, \cdot), \psi_0 \rangle_{C^\gamma \times h^\sigma}|$ is always bounded for $T_0 < t/2 < T$ and for any molecule ψ_0 : we have proven Theorem 1 by a duality argument. The proof of Theorems 2-4 is essentially the same. ■

Remark 4.3 (Hölder modulus of continuity) *Observe from Theorem 7 and the previous arguments that we actually have a control on the Hölder modulus of continuity of the solution θ . Namely, for all $0 < T_0 < \frac{t}{2} < T$, $0 < \gamma < \frac{1}{4}$,*

$$\|\theta(t, \cdot)\|_{C^\gamma} \leq CT_0^{-\frac{n}{p}-\gamma} \|\theta_0\|_{L^p}.$$

Let us quote the related result obtained by [9] in the particular setting of the SQG equation who derive controls of the following type:

$$\|\theta(t, \cdot)\|_{C^\gamma} \leq C\|\theta_0\|_{L^\infty},$$

with $\gamma := \gamma(\|\theta_0\|_{L^\infty}) < 1/4$.

4.1 Molecule's evolution

The following theorem shows how the molecular properties are deformed with the evolution for a small time s_0 .

Theorem 8 *Fix $t \in]0, T[$. Set σ , γ and ω real numbers such that $\frac{n}{n+1} < \sigma < 1$, $\gamma = n(\frac{1}{\sigma} - 1)$, $0 < \gamma < \omega < 1$. Let $\psi(s_0, x)$ be a solution at time s_0 of problem (4.5). We assume as for Theorem 7 that $0 < \alpha < 2$, $n(n-1) \vee 2n < p < +\infty$ and that the drift satisfies the hypotheses of Theorems 1-4. Then, there exist positive constants K and ϵ small enough such that if ψ_0 is a small molecule in the sense of Definition 4.1 for the local Hardy space $h^\sigma(\mathbb{R}^n)$, then for all time $0 < s_0 \leq \epsilon r^\alpha$, we have the following estimates:*

$$\int_{\mathbb{R}^n} |\psi(s_0, x)| |x - x(s_0)|^\omega dx \leq ((\zeta r)^\alpha + K s_0)^{\frac{\omega-\gamma}{\alpha}}, \quad (4.7)$$

$$\|\psi(s_0, \cdot)\|_{L^\infty} \leq \frac{1}{((\zeta r)^\alpha + K s_0)^{\frac{n+\gamma}{\alpha}}}, \quad (4.8)$$

$$\|\psi(s_0, \cdot)\|_{L^1} \leq \frac{2v_n^{\frac{\omega}{n+\omega}}}{((\zeta r)^\alpha + K s_0)^{\frac{\gamma}{\alpha}}}, \quad (4.9)$$

where v_n denotes the volume of the n -dimensional unit ball.

The new molecule's center $x(s_0)$ used in formula (4.7) is given by the evolution of the differential system

$$\begin{cases} x'(s) &= \overline{A_{[\theta, \rho]}}(t - s, x(s)) = \int_{\mathbb{R}^n} A_{[\theta]}(t - s, x(s) - y) \varphi_\rho(y) dy, s \in [0, s_0], \\ x(0) &= x_0, \end{cases} \quad (4.10)$$

where $\varphi_\rho(s, x) = \frac{1}{\rho^n} \varphi(\frac{x}{\rho})$, here φ is a positive function in $C_0^\infty(\mathbb{R}^n)$ such that $\text{supp}(\varphi) \subset B(0, 1)$ and where $\rho = \zeta^{\beta_1} r$ and $\beta_1 > 1$ will be specified later on. In the previous controls and in the dynamics for the evolution of the center, the parameter $\zeta = \zeta(\alpha, \omega, \gamma, \mu) > 1$, to be chosen further, is the same as in Definition 4.1.

Remark 4.4

- 1) The expression (4.10) explains the transport of the center of the molecule using the velocity $A_{[\theta]}$. The same definition is applicable to the drifts $A_{[(-\Delta)^{-\frac{n}{2}} \theta]}$ and $A_{[(-\Delta)^{\frac{n}{2}} \theta]}$ given in Theorems 3 and 4 respectively. We denote the new center of the molecule by $x(s_0) = x_{s_0}$.

- 2) By the maximum principle, it is enough to treat the case $0 < ((\zeta r)^\alpha + K s_0) < 1$ since s_0 is very small: otherwise the L^1 control will be trivial for time s_0 and beyond.
- 3) We will always assume $0 < \gamma < \omega < \frac{1}{4}$. Moreover for Theorems 1-4 we assume the following relationship: $1/2 < \delta < \alpha < 2$.
- 4) The hypothesis $\alpha = \frac{p+n}{p+1}$ (which is common to Theorems 1-2) can be rewritten as $\alpha = 1 - \frac{\alpha-n}{p}$ and this last formula will be helpful in the computations below.

Proof of the Theorem 8. We will adopt the following strategy: the first step is given by a study of the small Concentration condition (4.7) and in a second step we prove the Height condition (4.8). With these two conditions at hand, the L^1 estimate (4.9) will be easily obtained.

1) Concentration condition

For $s \in [0, s_0]$, we consider the functions $\Omega_s(x) = |x - x(s)|^\omega$ and $\psi(x) = \psi_+(x) - \psi_-(x)$ where the functions $\psi_\pm(x) \geq 0$ have disjoint support. We will denote by $\psi_\pm(s_0, x)$ two solutions of the dual equation (4.5) at time s_0 with $\psi_\pm(0, x) = \psi_\pm(x)$. We can use the positivity principle (see [7] for a proof, recall that for ψ we are in a linear framework) and thus by linearity we have

$$|\psi(s_0, x)| = |\psi_+(s_0, x) - \psi_-(s_0, x)| \leq \psi_+(s_0, x) + \psi_-(s_0, x),$$

and we can write $\int_{\mathbb{R}^n} |\psi(s_0, x)| \Omega_{s_0}(x) dx \leq \int_{\mathbb{R}^n} \psi_+(s_0, x) \Omega_{s_0}(x) dx + \int_{\mathbb{R}^n} \psi_-(s_0, x) \Omega_{s_0}(x) dx$, so we only have to treat one of the integrals on the right hand side above. We have for all $s \in [0, s_0]$:

$$\begin{aligned} I_s &= \left| \partial_s \int_{\mathbb{R}^n} \Omega_s(x) \psi_+(s, x) dx \right| \\ &= \left| \int_{\mathbb{R}^n} \partial_s \Omega_s(x) \psi_+(s, x) + \Omega_s(x) (-\nabla \cdot [A_{[\theta]}(t-s, x) \psi_+(s, x)] - \mathcal{L}^\alpha \psi_+(s, x)) dx \right| \\ &= \left| \int_{\mathbb{R}^n} -\nabla \Omega_s(x) \cdot x'(s) \psi_+(s, x) + \Omega_s(x) (-\nabla \cdot [A_{[\theta]}(t-s, x) \psi_+(s, x)] - \mathcal{L}^\alpha \psi_+(s, x)) dx \right|. \end{aligned}$$

Integrating by parts we obtain

$$I_s = \left| \int_{\mathbb{R}^n} -\nabla \Omega_s(x) \cdot (x'(s) - A_{[\theta]}(t-s, x)) \psi_+(s, x) - \Omega_s(x) \mathcal{L}^\alpha \psi_+(s, x) dx \right|.$$

Since the operator \mathcal{L}^α is symmetric and using the definition of $x'(s)$ given in (4.10) we have

$$I_s \leq c \int_{\mathbb{R}^n} |x - x(s)|^{\omega-1} |A_{[\theta]}(t-s, x) - \overline{A_{[\theta, \rho]}}(t-s, x(s))| |\psi_+(s, x)| dx + c \int_{\mathbb{R}^n} |\mathcal{L}^\alpha \Omega_s(x)| |\psi_+(s, x)| dx$$

$$I_s \leq c(I_{s,1} + I_{s,2}). \tag{4.11}$$

We will study separately each of the integrals $I_{s,1}$ and $I_{s,2}$ with two propositions.

Proposition 4.1 *If $0 < \gamma < \omega < \frac{1}{4}$, $0 < \delta < \alpha < 2$ and if $n(n-1) \vee 2n < p < +\infty$, we have for the integral $I_{s,1}$ in (4.11) the estimate:*

$$\int_0^{s_0} I_{s,1} ds \leq \eta_1 r^{\omega-\alpha-\gamma},$$

where $\eta_1 = \eta_1(\zeta, \alpha, q, n)$ is such that the quantity $\frac{\eta_1}{\zeta^{(\omega-\alpha-\gamma)}}$ can be made very small and where $\zeta > 1$ is the same parameter of Definition 4.1.

Proof. Consider $0 < \beta_0 < 1 < \beta_1 < 2$ two parameters. Let $\zeta \gg 1$ and $0 < r \ll 1$ be such that $\rho = \zeta^{\beta_1} r < 1$. For a given $s \in [0, s_0]$, we write $\mathbb{R}^n = B_{\rho, s} \cup \bigcup_{k \geq 1} E_{k, s}$ where

$$B_{\rho, s} = \{x \in \mathbb{R}^n : |x - x(s)| \leq \rho\} \quad \text{and} \quad E_{k, s} = \{x \in \mathbb{R}^n : 2^{k-1}\rho < |x - x(s)| \leq 2^k \rho\}, \quad (4.12)$$

and we write

$$I_{s,1} = \int_{B_{\rho, s}} |x - x(s)|^{\omega-1} |A_{[\theta]}(t-s, x) - \overline{A_{[\theta, \rho]}}(t-s, x(s))| |\psi(s, x)| dx \quad (4.13)$$

$$+ \sum_{k \geq 1} \int_{E_{k, s}} |x - x(s)|^{\omega-1} |A_{[\theta]}(t-s, x) - \overline{A_{[\theta, \rho]}}(t-s, x(s))| |\psi(s, x)| dx. \quad (4.14)$$

We will study each of these terms separately.

- For (4.13) we define $\rho_0 = \zeta^{\beta_0} r$. Since $\beta_0 < \beta_1$ and $\zeta > 1$, we have $\rho_0 < \rho$ and we can then consider $B_{\rho, s} = B_{\rho_0, s} \cup \mathcal{C}(\rho_0, \rho, s)$ with $\mathcal{C}(\rho_0, \rho, s) = \{x \in \mathbb{R}^n : \rho_0 < |x - x(s)| \leq \rho\}$. So, we need to study $I_{B_{\rho_0, s}} + I_{\mathcal{C}(\rho_0, \rho, s)}$ where

$$I_{B_{\rho_0, s}} = \int_{B_{\rho_0, s}} |x - x(s)|^{\omega-1} |A_{[\theta]}(t-s, x) - \overline{A_{[\theta, \rho]}}(t-s, x(s))| |\psi(s, x)| dx,$$

and

$$I_{\mathcal{C}(\rho_0, \rho, s)} = \int_{\mathcal{C}(\rho_0, \rho, s)} |x - x(s)|^{\omega-1} |A_{[\theta]}(t-s, x) - \overline{A_{[\theta, \rho]}}(t-s, x(s))| |\psi(s, x)| dx.$$

We set

$$\frac{1}{p} + \frac{1}{p'} = 1, \quad \text{with } 1 < p' < \frac{n}{1-\omega} \quad \text{and} \quad \frac{1}{m} + \frac{1}{p} + \frac{1}{z} = 1 \quad \text{with } m > \frac{n}{1-\omega}. \quad (4.15)$$

Then, by the Hölder inequality we have:

$$\begin{aligned} I_{B_{\rho_0, s}} + I_{\mathcal{C}(\rho_0, \rho, s)} &\leq \|\psi(s, \cdot)\|_{L^\infty} \times \| |x - x(s)|^{\omega-1} \|_{L^{p'}(B_{\rho_0, s})} \times \|A_{[\theta]}(t-s, \cdot) - \overline{A_{[\theta, \rho]}}(t-s, \cdot)\|_{L^p(B_{\rho_0, s})} \\ &\quad + \left(\int_{\mathcal{C}(\rho_0, \rho, s)} |A_{[\theta]}(t-s, \cdot) - \overline{A_{[\theta, \rho]}}(t-s, x(s))|^p dx \right)^{1/p} \\ &\quad \times \left(\int_{\mathcal{C}(\rho_0, \rho, s)} |x - x(s)|^{(\omega-1)m} dx \right)^{1/m} \times \|\psi(s, \cdot)\|_{L^z(\mathcal{C}(\rho_0, \rho, s))}. \end{aligned}$$

Since $1 < p' < \frac{n}{1-\omega}$ and $\frac{n}{1-\omega} < m$, we can write

$$\begin{aligned} I_{B_{\rho_0, s}} + I_{\mathcal{C}(\rho_0, \rho, s)} &\leq C \|\psi(s, \cdot)\|_{L^\infty} \times \rho_0^{\omega-1 + \frac{n}{p'}} \times \|A_{[\theta]}(t-s, \cdot) - \overline{A_{[\theta, \rho]}}(t-s, x(s))\|_{L^p(B_{\rho_0, s})} \\ &\quad + \left(\int_{\mathcal{C}(\rho_0, \rho, s)} |A_{[\theta]}(t-s, \cdot) - \overline{A_{[\theta, \rho]}}(t-s, x(s))|^p dx \right)^{1/p} \\ &\quad \times \left(\rho_0^{m(\omega-1)+n} - \rho^{m(\omega-1)+n} \right)^{1/m} \times \|\psi(s, \cdot)\|_{L^z(\mathcal{C}(\rho_0, \rho, s))}, \end{aligned}$$

and since $\rho_0 < \rho$ we obtain

$$\begin{aligned} I_{B_{\rho_0, s}} + I_{\mathcal{C}(\rho_0, \rho, s)} &\leq C \left(\|\psi(s, \cdot)\|_{L^\infty} \times \rho_0^{\omega-1 + \frac{n}{p'}} + \left(\rho_0^{m(\omega-1)+n} - \rho^{m(\omega-1)+n} \right)^{1/m} \times \|\psi(s, \cdot)\|_{L^z(B_{\rho, s})} \right) \\ &\quad \times \|A_{[\theta]}(t-s, \cdot) - \overline{A_{[\theta, \rho]}}(t-s, x(s))\|_{L^p(B_{\rho, s})}. \quad (4.16) \end{aligned}$$

Remark 4.5 (Morrey-Campanato versus Besov) *It is worth noting here that it is precisely at this point that we will use the Besov norm control instead of the Morrey-Campanato boundedness information. Indeed, having obtained the inequality (4.16) we have the choice to use either the first inequality of (4.4) to control the quantity $\|A_{[\theta]}(t-s, \cdot) - \overline{A_{[\theta, \rho]}}(t-s, x(s))\|_{L^p(B_{\rho, s})}$, which will lead us (following [7]) to relationship (1.2), or the second inequality of (4.4) which will allow us to consider a different smoothness degree for the Lévy-type operator: following the choice made, we will observe a very interesting competition between the Morrey-Campanato regularity versus the Besov regularity.*

We have now the following lemma, proven in the appendix, which is the key of our computations

Lemma 4.1 *Under the hypotheses of Theorems 1-2 and if $\overline{A_{[\theta, \rho]}}(t-s, x(s))$ is given by (4.10), we have for $1 < p < +\infty$, $0 < \alpha < 2$ and almost all $s \in [0, T]$:*

$$\|A_{[\theta]}(t-s, \cdot) - \overline{A_{[\theta, \rho]}}(t-s, x(s))\|_{L^p(B_{\rho, s})} \leq C \rho^{\frac{\alpha}{p}} \|A_{[\theta]}(t-s, \cdot)\|_{\dot{B}_p^{\alpha/p, p}(\mathbb{R}^n)}.$$

Remark 4.6 *This key lemma admits the following generalization that will be used in Theorems 3 and 4. Indeed, if $0 < \eta < 1$ is a fixed (small) parameter such that respectively $0 < \frac{\alpha}{p} + \eta < 1$ and $0 < \frac{\alpha}{p} - \eta < 1$, then for almost all $s \in [0, T]$:*

$$\begin{aligned} \|A_{[(-\Delta)^{-\frac{\eta}{2}\theta]}(t-s, \cdot) - \overline{A_{[(-\Delta)^{-\frac{\eta}{2}\theta, \rho]}}(t-s, x(s))\|_{L^p(B_{\rho, s})} &\leq C \rho^{\frac{\alpha}{p} + \eta} \\ &\times \|A_{[(-\Delta)^{-\frac{\eta}{2}\theta]}(t-s, \cdot)\|_{\dot{B}_p^{\alpha/p + \eta, p}(\mathbb{R}^n)} \end{aligned} \quad (4.17)$$

$$\begin{aligned} \|A_{[(\Delta)^{\frac{\eta}{2}\theta]}(t-s, \cdot) - \overline{A_{[(\Delta)^{\frac{\eta}{2}\theta, \rho]}}(t-s, \cdot)\|_{L^p(B_{\rho, s})} &\leq C \rho^{\frac{\alpha}{p} - \eta} \\ &\times \|A_{[(\Delta)^{\frac{\eta}{2}\theta]}(t-s, x(s))\|_{\dot{B}_p^{\alpha/p - \eta, p}(\mathbb{R}^n)}. \end{aligned} \quad (4.18)$$

The proof of these inequalities follows the same lines as of the one presented in Lemma 4.1.

Now we apply Lemma 4.1 in (4.16) and we obtain

$$\begin{aligned} I_{B_{\rho_0, s}} + I_{C(\rho_0, \rho, s)} &\leq C \left(\|\psi(s, \cdot)\|_{L^\infty} \times \rho_0^{\omega-1 + \frac{n}{p'}} + (\rho_0^{m(\omega-1)+n} - \rho^{m(\omega-1)+n})^{1/m} \times \|\psi(s, \cdot)\|_{L^z(B_{\rho, s})} \right) \\ &\times \rho^{\frac{\alpha}{p}} \|A_{[\theta]}(t-s, \cdot)\|_{\dot{B}_p^{\alpha/p, p}(\mathbb{R}^n)}. \end{aligned}$$

If we define

$$\varepsilon = \frac{\ln [1 - \zeta^{(\beta_1 - \beta_0)(m(\omega-1)+n)}]}{(m(\omega-1) + n)\beta_0 \ln(\zeta)}, \quad (4.19)$$

which is a positive quantity since $m(\omega-1) + n < 0$ and recalling that $\rho = \zeta^{\beta_1} r$ and $\rho_0 = \zeta^{\beta_0} r$, with $\beta_1 > \beta_0$ and $\zeta > 1$, we obtain

$$\left(\rho_0^{m(\omega-1)+n} - \rho^{m(\omega-1)+n} \right)^{1/m} = (\zeta^{\beta_0(1+\varepsilon)} r)^{\omega-1 + \frac{n}{m}},$$

and we can write

$$\begin{aligned} I_{B_{\rho_0, s}} + I_{C(\rho_0, \rho, s)} &\leq C \left((\zeta^{\beta_0} r)^{\omega-1 + \frac{n}{p'}} \times \|\psi(s, \cdot)\|_{L^\infty} + (\zeta^{\beta_0(1+\varepsilon)} r)^{\omega-1 + \frac{n}{m}} \times \|\psi(s, \cdot)\|_{L^z(B_{\rho, s})} \right) \\ &\times (\zeta^{\beta_1} r)^{\frac{\alpha}{p}} \times \|A_{[\theta]}(t-s, \cdot)\|_{\dot{B}_p^{\alpha/p, p}(\mathbb{R}^n)}. \end{aligned}$$

At this point, we use the maximum principle for the molecule $\psi(s, \cdot)$ (as well as (4.1) and Remark 4.1) to derive:

$$\|\psi(s, \cdot)\|_{L^\infty} \leq \|\psi_0\|_{L^\infty} \leq (\zeta r)^{-(n+\gamma)} \quad \|\psi(s, \cdot)\|_{L^z(B_{\rho,s})} \leq \|\psi_0\|_{L^z(\mathbb{R}^n)} \leq C(\zeta r)^{-n+\frac{n}{z}-\gamma},$$

which lead us to

$$\begin{aligned} I_{B_{\rho_0,s}} + I_{C(\rho_0,\rho,s)} &\leq C \left((\zeta^{\beta_0} r)^{\omega-1+\frac{n}{p'}} \times (\zeta r)^{-(n+\gamma)} + (\zeta^{\beta_0(1+\varepsilon)} r)^{\omega-1+\frac{n}{m}} \times (\zeta r)^{-n+\frac{n}{z}-\gamma} \right) \\ &\quad \times (\zeta^{\beta_1} r)^{\frac{\alpha}{p}} \times \|A_{[\theta]}(t-s, \cdot)\|_{\dot{B}_p^{\alpha/p,p}(\mathbb{R}^n)}. \end{aligned}$$

Since we have the Besov stability property for the drift given in (4.4) -which is a common hypothesis for Theorems 1-2- we can write

$$\begin{aligned} \int_0^{s_0} \|A_{[\theta]}(t-s, \cdot)\|_{\dot{B}_p^{\alpha/p,p}(\mathbb{R}^n)} ds &\leq s_0^{1/p'} \left(\int_0^{s_0} \|A_{[\theta]}(t-s, \cdot)\|_{\dot{B}_p^{\alpha/p,p}(\mathbb{R}^n)}^p ds \right)^{1/p} \\ &\leq \|A_{[\theta]}\|_{L^p([0,T], \dot{B}_p^{\alpha/p,p})} \leq D_A \|\theta\|_{L^p([0,T], \dot{B}_p^{\alpha/p,p})} \stackrel{(1.6)}{\leq} C_A \|\theta_0\|_{L^p} = \mu < +\infty, \end{aligned}$$

and we obtain

$$\begin{aligned} \int_0^{s_0} (I_{B_{\rho_0,s}} + I_{C(\rho_0,\rho,s)}) ds &\leq C\mu \left((\zeta^{\beta_0} r)^{\omega-1+\frac{n}{p'}} (\zeta r)^{-(n+\gamma)} + (\zeta^{\beta_0(1+\varepsilon)} r)^{\omega-1+\frac{n}{m}} (\zeta r)^{-n+\frac{n}{z}-\gamma} \right) \\ &\quad \times (\zeta^{\beta_1} r)^{\frac{\alpha}{p}}. \end{aligned} \tag{4.20}$$

Remark 4.7 *In the case of Theorem 3, we use (4.17) to obtain:*

$$\begin{aligned} \int_0^{s_0} (I_{B_{\rho_0,s}} + I_{C(\rho_0,\rho,s)}) ds &\leq C \left((\zeta^{\beta_0} r)^{\omega-1+\frac{n}{p'}} \times (\zeta r)^{-(n+\gamma)} + (\zeta^{\beta_0(1+\varepsilon)} r)^{\omega-1+\frac{n}{m}} \times (\zeta r)^{-n+\frac{n}{z}-\gamma} \right) \\ &\quad \times (\zeta^{\beta_1} r)^{\frac{\alpha}{p}+\eta} \times \left(\int_0^{s_0} \|A_{[(-\Delta)^{-\frac{\eta}{2}}\theta]}(t-s, \cdot)\|_{\dot{B}_p^{\alpha/p+\eta,p}(\mathbb{R}^n)}^p ds \right)^{1/p}, \end{aligned}$$

moreover, using hypothesis (2.13), Besov spaces properties, the uniform control over the Besov norm stated in assumption (b₃) of Theorem 3 and the maximum principle, we have:

$$\begin{aligned} \|A_{[(-\Delta)^{-\frac{\eta}{2}}\theta]}\|_{L^p([0,T], \dot{B}_p^{\alpha/p+\eta,p})} &\leq \|(-\Delta)^{-\frac{\eta}{2}}\theta\|_{L^p([0,T], \dot{B}_p^{\alpha/p+\eta,p})} \simeq \|\theta\|_{L^p([0,T], \dot{B}_p^{\alpha/p,p})} \\ &\leq D_A \|\theta_0\|_{L^p} = \mu < +\infty, \end{aligned}$$

and thus inequality (4.20) may be replaced by

$$\begin{aligned} \int_0^{s_0} (I_{B_{\rho_0,s}} + I_{C(\rho_0,\rho,s)}) ds &\leq C\mu \left((\zeta^{\beta_0} r)^{\omega-1+\frac{n}{p'}} (\zeta r)^{-(n+\gamma)} + (\zeta^{\beta_0(1+\varepsilon)} r)^{\omega-1+\frac{n}{m}} (\zeta r)^{-n+\frac{n}{z}-\gamma} \right) \\ &\quad \times (\zeta^{\beta_1} r)^{\frac{\alpha}{p}+\eta} \end{aligned}$$

For Theorem 4, in a completely similar fashion, using (4.18) we obtain

$$\begin{aligned} \int_0^{s_0} (I_{B_{\rho_0,s}} + I_{C(\rho_0,\rho,s)}) ds &\leq C\mu \left((\zeta^{\beta_0} r)^{\omega-1+\frac{n}{p'}} (\zeta r)^{-(n+\gamma)} + (\zeta^{\beta_0(1+\varepsilon)} r)^{\omega-1+\frac{n}{m}} (\zeta r)^{-n+\frac{n}{z}-\gamma} \right) \\ &\quad \times (\zeta^{\beta_1} r)^{\frac{\alpha}{p}-\eta}. \end{aligned}$$

Once we have obtained inequality (4.20) we continue our study of the molecule's evolution. Indeed, using the identity $\alpha = 1 - \frac{\alpha-n}{p}$, which is common to Theorems 1-2 (see point 4) in Remark 4.4) we obtain recalling as well (4.15):

$$\int_0^{s_0} (I_{B_{\rho_0,s}} + I_{C(\rho_0,\rho,s)}) ds \leq C\mu \times r^{\omega-\alpha-\gamma} \times \left(\zeta^{\beta_0(\omega-1+\frac{n}{p'})+\beta_1\frac{\alpha}{p}-n-\gamma} + \zeta^{\beta_0(1+\varepsilon)(\omega-1+\frac{n}{m})+\beta_1\frac{\alpha}{p}-n+\frac{n}{z}-\gamma} \right). \quad (4.21)$$

Remark 4.8 For Theorem 3, using relationship (2.12) we have $\alpha = 1 + \frac{n-\alpha}{p} - \eta$. Inequality (4.21) becomes

$$\int_0^{s_0} (I_{B_{\rho_0,s}} + I_{C(\rho_0,\rho,s)}) ds \leq C\mu \times r^{\omega-\alpha-\gamma} \times \left(\zeta^{\beta_0(\omega-1+\frac{n}{p'})+\beta_1(\frac{\alpha}{p}+\eta)-n-\gamma} + \zeta^{\beta_0(1+\varepsilon)(\omega-1+\frac{n}{m})+\beta_1(\frac{\alpha}{p}+\eta)-n+\frac{n}{z}-\gamma} \right).$$

Whereas for Theorem 4, with relationship (2.17) we have $\alpha = 1 + \frac{n-\alpha}{p} + \eta$ and thus inequality (4.21) becomes

$$I_{B_{\rho_0,s}} + I_{C(\rho_0,\rho,s)} \leq C\mu \times r^{\omega-\alpha-\gamma} \times \left(\zeta^{\beta_0(\omega-1+\frac{n}{p'})+\beta_1(\frac{\alpha}{p}-\eta)-n-\gamma} + \zeta^{\beta_0(1+\varepsilon)(\omega-1+\frac{n}{m})+\beta_1(\frac{\alpha}{p}-\eta)-n+\frac{n}{z}-\gamma} \right).$$

Once we have inequality (4.21), we want to keep the information of the molecule's relative size $r^{\omega-\alpha-\gamma}$ and we want to absorb the constants, thus if we denote $\eta_{0,1}$ by

$$\eta_{0,1} = C\mu \left(\zeta^{\beta_0(\omega-1+\frac{n}{p'})+\beta_1\frac{\alpha}{p}-n-\gamma} + \zeta^{\beta_0(1+\varepsilon)(\omega-1+\frac{n}{m})+\beta_1\frac{\alpha}{p}-n+\frac{n}{z}-\gamma} \right),$$

we can write

$$\int_0^{s_0} (I_{B_{\rho_0,s}} + I_{C(\rho_0,\rho,s)}) ds \leq \eta_{0,1} r^{\omega-\alpha-\gamma}. \quad (4.22)$$

We remark now that $\frac{\eta_{0,1}}{\zeta^{(\omega-\alpha-\gamma)}}$ can be made small, indeed we have

$$\begin{aligned} \frac{\eta_{0,1}}{\zeta^{(\omega-\alpha-\gamma)}} &= C\mu \left(\zeta^{\beta_0(\omega-1+\frac{n}{p'})+\beta_1\frac{\alpha}{p}-n-\gamma-(\omega-\alpha-\gamma)} + \zeta^{\beta_0(1+\varepsilon)(\omega-1+\frac{n}{m})+\beta_1\frac{\alpha}{p}-n+\frac{n}{z}-\gamma-(\omega-\alpha-\gamma)} \right) \\ &= C\mu \left(\zeta^{\beta_0(\omega-1+\frac{n}{p'})+\beta_1\frac{\alpha}{p}-n-\omega+\alpha} + \zeta^{\beta_0(1+\varepsilon)(\omega-1+\frac{n}{m})+\beta_1\frac{\alpha}{p}-n+\frac{n}{z}-\omega+\alpha} \right), \end{aligned} \quad (4.23)$$

and since the parameter $\zeta \gg 1$, it is enough to verify that the quantities $\beta_0(\omega-1+\frac{n}{p'})+\beta_1\frac{\alpha}{p}-n-\omega+\alpha$ and $\beta_0(1+\varepsilon)(\omega-1+\frac{n}{m})+\beta_1\frac{\alpha}{p}-n+\frac{n}{z}-\omega+\alpha$ can be chosen to be both negative.

If we set $\beta_0 = 1 - \nu_0$ and $\beta_1 = 1 + \nu_1$ with $0 < \nu_1 \ll \nu_0 < 1$ and recalling the relationship $\alpha = 1 - \frac{\alpha-n}{p}$, the negativity of $\beta_0(\omega-1+\frac{n}{p'})+\beta_1\frac{\alpha}{p}-n-\omega+\alpha$ is equivalent to

$$\nu_1 \frac{\alpha}{p} < \nu_0 \left(\frac{n}{p'} + \omega - 1 \right), \quad (4.24)$$

but since from (4.15), $1 < p' < \frac{n}{1-\omega}$ and $\nu_1 \ll \nu_0$, we obtain that the first power of ζ in (4.23) is negative.

Remark 4.9 For Theorem 3, we need to study the negativity of the quantity $\beta_0(\omega - 1 + \frac{n}{p'}) + \beta_1(\frac{\alpha}{p} + \eta) - n - \omega + \alpha$, and the condition (4.24) changes as follows $\nu_1(\frac{\alpha}{p} + \eta) < \nu_0(\frac{n}{p'} + \omega - 1)$, while for Theorem 4 we need to study $\beta_0(\omega - 1 + \frac{n}{p'}) + \beta_1(\frac{\alpha}{p} - \eta) - n - \omega + \alpha$, and the condition obtained is $\nu_1(\frac{\alpha}{p} - \eta) < \nu_0(\frac{n}{p'} + \omega - 1)$. These conditions are fulfilled as long as $1 < p' < \frac{n}{1-\omega}$ and $\nu_1 \ll \nu_0$.

With the same relationships as above for β_0, β_1, ν_0 and ν_1 , the negativity of $\beta_0(1 + \varepsilon)(\omega - 1 + \frac{n}{m}) + \beta_1\frac{\alpha}{p} - n + \frac{n}{z} - \omega + \alpha$ is equivalent to

$$(\omega - 1 + \frac{n}{m})(\varepsilon - \nu_0(1 + \varepsilon)) + \nu_1(1 - \alpha + \frac{n}{p}) < 0, \quad (4.25)$$

where $\frac{n}{1-\omega} < m < +\infty$ and ε is given by (4.19). Since $\varepsilon = \varepsilon(\nu_0, \nu_1) \xrightarrow{\nu_0 \rightarrow 0} +\infty$, the negativity of this exponent of ζ follows for ν_0 small enough.

Remark 4.10 As before, for Theorem 3 we need to study the quantity $\beta_0(1 + \varepsilon)(\omega - 1 + \frac{n}{m}) + \beta_1(\frac{\alpha}{p} + \eta) - n + \frac{n}{z} - \omega + \alpha$, but since we have $\alpha = 1 + \frac{n-\alpha}{p} - \eta$ (see Remark 4.8), the negativity of this quantity is equivalent to the condition (4.25). For Theorem 4 we study $\beta_0(1 + \varepsilon)(\omega - 1 + \frac{n}{m}) + \beta_1(\frac{\alpha}{p} - \eta) - n + \frac{n}{z} - \omega + \alpha$, but since $\alpha = 1 + \frac{n-\alpha}{p} + \eta$ (see also Remark 4.8), we obtain the same condition (4.25).

Thus, since all the exponents in (4.23) are negative, it is possible to take ζ big enough in order to make $\frac{\eta_{0,1}}{\zeta^{(\omega-\alpha-\gamma)}}$ small.

- We study now (4.14). For $s \in [0, s_0]$, let us denote by $I_{E_{k,s}}$ the integral

$$I_{E_{k,s}} = \int_{E_{k,s}} |x - x(s)|^{\omega-1} |A_{[\theta]}(t - s, \cdot) - \overline{A_{[\theta,\rho]}}(t - s, x(s))| |\psi(s, x)| dx.$$

As $\omega - 1 < 0$, over $E_{k,s}$ we have $|x - x(s)|^{\omega-1} \leq C(2^k \rho)^{\omega-1}$ and we write

$$I_{E_{k,s}} \leq C(2^k \rho)^{\omega-1} \int_{B_{2^k \rho, s}} |A_{[\theta]}(t - s, \cdot) - \overline{A_{[\theta,\rho]}}(t - s, x(s))| |\psi(s, x)| dx,$$

where we have denoted $B_{2^k \rho, s} = B(x(s), 2^k \rho)$, then we obtain

$$I_{E_{k,s}} \leq C(2^k \rho)^{\omega-1} \|A_{[\theta]}(t - s, \cdot) - \overline{A_{[\theta,\rho]}}(t - s, x(s))\|_{L^p(B_{2^k \rho, s})} \|\psi(s, \cdot)\|_{L^{p'}(B_{2^k \rho, s})}, \quad (4.26)$$

where we used the Hölder inequality with $\frac{1}{p} + \frac{1}{p'} = 1$. We will need the following lemma which is proved in the appendix.

Lemma 4.2 Under the general hypotheses of Theorems 1-2 and if $\overline{A_{[\theta,\rho]}}(t - s, \cdot)$ is given by (4.10), we have for almost all $s \in [0, s_0]$,

$$\|A_{[\theta]}(t - s, \cdot) - \overline{A_{[\theta,\rho]}}(t - s, x(s))\|_{L^p(B_{2^k \rho, s})} \leq C(2^k \rho)^{\frac{\alpha}{p}} \times 2^{\frac{kn}{p}} \times \|A_{[\theta]}(t - s, \cdot)\|_{\dot{B}_p^{\alpha/p, p}(\mathbb{R}^n)}.$$

Remark 4.11 *This lemma admits the following generalization: if $0 < \eta < 1$ is a fixed (small) parameter such that $0 < \frac{\alpha}{p} + \eta < 1$ and $0 < \frac{\alpha}{p} - \eta < 1$, then we have for almost all $s \in [0, s_0]$,*

$$\begin{aligned} \|A_{[(-\Delta)^{-\frac{\eta}{2}\theta]}(t-s, \cdot) - \overline{A_{[(-\Delta)^{-\frac{\eta}{2}\theta, \rho]}(t-s, \cdot)}\|_{L^p(B_{2^k\rho, s})} &\leq C(2^k\rho)^{\frac{\alpha}{p}+\eta} \\ &\times 2^{\frac{kn}{p}} \|A_{[(-\Delta)^{-\frac{\eta}{2}\theta]}(t-s, \cdot)\|_{\dot{B}_p^{\alpha/p+\eta}(\mathbb{R}^n)}. \end{aligned} \quad (4.27)$$

The previous inequality will be used in Theorem 3, and for Theorem 4 we will need the following estimate, for almost all $s \in [0, s_0]$:

$$\begin{aligned} \|A_{[(-\Delta)^{\frac{\eta}{2}\theta]}(t-s, \cdot) - \overline{A_{[(-\Delta)^{\frac{\eta}{2}\theta, \rho]}(t-s, \cdot)}\|_{L^p(B_{2^k\rho, s})} &\leq C(2^k\rho)^{\frac{\alpha}{p}-\eta} \\ &\times 2^{\frac{kn}{p}} \|A_{[(-\Delta)^{\frac{\eta}{2}\theta]}(t-s, \cdot)\|_{\dot{B}_p^{\alpha/p-\eta}(\mathbb{R}^n)}. \end{aligned} \quad (4.28)$$

The proof of these inequalities follows the same lines as of the one presented in Lemma 4.2.

If we apply Lemma 4.2 in inequality (4.26) we obtain

$$I_{E_{k,s}} \leq C(2^k\rho)^{\omega-1} \left((2^k\rho)^{\frac{\alpha}{p}} \times 2^{\frac{kn}{p}} \times \|A_{[\theta]}(t-s, \cdot)\|_{\dot{B}_p^{\alpha/p}(\mathbb{R}^n)} \|\psi(s, \cdot)\|_{L^{p'}(\mathbb{R}^n)} \right),$$

and using again the maximum principle for the molecule³ $\psi(s, \cdot)$ we have

$$I_{E_{k,s}} \leq C(2^k\rho)^{\omega-1} \times (\zeta r)^{-n+\frac{n}{p'}-\gamma} \times \left((2^k\rho)^{\frac{\alpha}{p}} \times 2^{\frac{kn}{p}} \times \|A_{[\theta]}(t-s, \cdot)\|_{\dot{B}_p^{\alpha/p}(\mathbb{R}^n)} \right).$$

Now, in the framework of Theorems 1-2 we have by hypothesis the Besov boundedness property $\|A_{[\theta]}\|_{L^p([0,T], \dot{B}_p^{\alpha/p,p})} \leq D_A \|\theta\|_{L^p([0,T], \dot{B}_p^{\alpha/p,p})} \leq D_A \|\theta_0\|_{L^p} = \mu < +\infty$, and we can write recalling from (4.15) that $\frac{1}{p} + \frac{1}{p'} = 1$:

$$\int_0^{s_0} I_{E_{k,s}} ds \leq C\mu(2^k\rho)^{\omega-1} \times (\zeta r)^{-\frac{n}{p}-\gamma} \times \left((2^k\rho)^{\frac{\alpha}{p}} \times 2^{\frac{kn}{p}} \right). \quad (4.29)$$

Remark 4.12 *For Theorem 3, using the inequality (4.27) and the estimates given in Remark 4.11 we have instead of (4.29) the following inequality*

$$\int_0^{s_0} I_{E_{k,s}} ds \leq C\mu(2^k\rho)^{\omega-1} \times (\zeta r)^{-\frac{n}{p}-\gamma} \times \left((2^k\rho)^{\frac{\alpha}{p}+\eta} \times 2^{\frac{kn}{p}} \right).$$

For Theorem 4, using (4.28) and Remark 4.7 we obtain

$$\int_0^{s_0} I_{E_{k,s}} ds \leq C\mu(2^k\rho)^{\omega-1} \times (\zeta r)^{-\frac{n}{p}-\gamma} \times \left((2^k\rho)^{\frac{\alpha}{p}-\eta} \times 2^{\frac{kn}{p}} \right).$$

Once we have at our disposal inequality (4.29), recalling that $\rho = \zeta^{\beta_1} r$ and $\alpha = 1 - \frac{\alpha-n}{p}$, we have the following expression

$$\int_0^{s_0} I_{E_{k,s}} ds \leq C\mu 2^{k(\omega-1+\frac{\alpha+n}{p})} \times \zeta^{\beta_1(\omega-1+\frac{\alpha}{p})-\frac{n}{p}-\gamma} \times r^{\omega-\alpha-\gamma}. \quad (4.30)$$

Since $0 < \omega < \frac{1}{4}$, $0 < \alpha < 2$, $2 \leq n$ and $n(n-1) \vee 2n < p < +\infty$, we have that $\omega - 1 + \frac{\alpha+n}{p} < 0$ and we can sum over k in order to obtain

$$\sum_{k \geq 1} \int_0^{s_0} I_{E_{k,s}} ds \leq C\mu \zeta^{\beta_1(\omega-1+\frac{\alpha}{p})-\frac{n}{p}-\gamma} \times r^{\omega-\alpha-\gamma}. \quad (4.31)$$

³Recall from the maximum principle that we have $\|\psi(s, \cdot)\|_{L^{p'}(\mathbb{R}^n)} \leq \|\psi_0\|_{L^{p'}(\mathbb{R}^n)} \leq C(\zeta r)^{-\frac{n}{p}-\gamma}$.

Remark 4.13 Using Remark 4.12, for Theorem 3 we have instead of (4.30) the following inequality

$$\int_0^{s_0} I_{E_{k,s}} ds \leq C\mu 2^{k(\omega-1+\frac{\alpha+n}{p}+\eta)} \times \zeta^{\beta_1(\omega-1+\frac{\alpha}{p}+\eta)-\frac{n}{p}-\gamma} \times r^{\omega-\alpha-\gamma},$$

and thus, if $\omega - 1 + \frac{\alpha+n}{p} + \eta < 0$ (which is the case since $0 < \omega < \frac{1}{4}$, $0 < \alpha < 2$, $2 \leq n$, $n(n-1) \vee 2n < p < +\infty$ and $0 < \eta < 1$ is assumed small enough), summing over k we obtain:

$$\sum_{k \geq 1} \int_0^{s_0} I_{E_{k,s}} ds \leq C\mu \zeta^{\beta_1(\omega-1+\frac{\alpha}{p}+\eta)-\frac{n}{p}-\gamma} \times r^{\omega-\alpha-\gamma}. \quad (4.32)$$

For Theorem 4 we have $\int_0^{s_0} I_{E_{k,s}} ds \leq C\mu 2^{k(\omega-1+\frac{\alpha+n}{p}-\eta)} \times \zeta^{\beta_1(\omega-1+\frac{\alpha}{p}-\eta)-\frac{n}{p}-\gamma} \times r^{\omega-\alpha-\gamma}$, but since $\omega - 1 + \frac{\alpha+n}{p} - \eta < 0$ we obtain

$$\sum_{k \geq 1} \int_0^{s_0} I_{E_{k,s}} ds \leq C\mu \zeta^{\beta_1(\omega-1+\frac{\alpha}{p}-\eta)-\frac{n}{p}-\gamma} \times r^{\omega-\alpha-\gamma}. \quad (4.33)$$

Now, coming back to the expression (4.31), setting $\eta_{1,1} := C\mu \zeta^{\beta_1(\omega-1+\frac{\alpha}{p})-\frac{n}{p}-\gamma}$, we observe that $\frac{\eta_{1,1}}{\zeta^{(\omega-\alpha-\gamma)}}$ can be made small. Indeed:

$$\frac{\eta_{1,1}}{\zeta^{(\omega-\alpha-\gamma)}} = C\mu \zeta^{\beta_1(\omega-1+\frac{\alpha}{p})-\frac{n}{p}-\omega+\alpha}.$$

Since $\zeta \gg 1$ we only need to verify that $\beta_1(\omega - 1 + \frac{\alpha}{p}) - \frac{n}{p} - \omega + \alpha < 0$, but since $\beta_1 = 1 + \nu_1$ and $\alpha = 1 - \frac{\alpha-n}{p}$, the negativity of this exponent is equivalent to $\omega + \frac{n}{p} < \alpha$ which is the case by hypothesis since $0 < \omega < \frac{1}{4}$, $1 < \alpha < 2$ (for Theorems 1 & 2) and $n(n-1) \vee 2n < p < +\infty$ with $2 \leq n$.

Remark 4.14 In order to absorb the constants in the expressions (4.32) and (4.33) we need to study the negativity of the quantities

$$\beta_1(\omega - 1 + \frac{\alpha}{p} + \eta) - \frac{n}{p} - \omega + \alpha < 0 \quad \text{and} \quad \beta_1(\omega - 1 + \frac{\alpha}{p} - \eta) - \frac{n}{p} - \omega + \alpha < 0,$$

but using the fact that $\frac{\alpha}{p} = 1 + \frac{n}{p} - \alpha - \eta$ for Theorem 3 and $\frac{\alpha}{p} = 1 + \frac{n}{p} - \alpha + \eta$ for Theorem 4 (see Remark 4.8), the negativity of these terms follows from the same condition $\omega + \frac{n}{p} < \alpha$.

Remark also that, in the case of Theorem 3, the condition $\omega + \frac{n}{p} < \alpha$ gives a lower bound for the smoothness degree α given in (2.12). Moreover, since $0 < \omega < \frac{1}{4}$ and $n(n-1) \vee 2n < p < +\infty$, we can obtain that $1/2 < \alpha < 1$.

More accurate bounds can be obtained, but this is enough to our purposes, in particular in the case of Theorem 3 we can consider smoothness degrees in the interval $1/2 < \alpha < 1$.

Now, in order to finish the proof of the Proposition 4.1, it remains to gather the estimate (4.22) with (4.31) to obtain

$$\begin{aligned} \int_0^{s_0} I_{s,1} ds &= \int_0^{s_0} (I_{B_{\rho_0,s}} + I_{C(\rho_0,\rho,s)} + \sum_{k \geq 1} I_{E_{k,s}}) ds \\ &\leq r^{\omega-\alpha-\gamma} (\eta_{0,1} + \eta_{1,1}) = r^{\omega-\alpha-\gamma} \eta_1, \end{aligned}$$

where $\eta_1 = \eta_{0,1} + \eta_{1,1}$ is such that $\frac{\eta_1}{\zeta^{(\omega-\alpha-\gamma)}}$ can be made very small. This concludes the proof of Proposition 4.1. \blacksquare

With the several remarks stated all along the proof of Proposition 4.1, we also have this estimate in the framework of Theorem 3 and Theorem 4.

The second step is given by the following proposition that relies only in the properties of the Lévy-type operator.

Proposition 4.2 *For the integral $I_{s,2}$ in (4.11) we have the following inequality:*

$$\int_0^{s_0} I_{s,2} ds \leq \eta_2 r^{\omega-\alpha-\gamma},$$

where $\omega - \delta + \frac{n}{p} < 0$ with $1/2 < \delta < \alpha < 2$ and where $\frac{\eta_2}{\zeta^{(\omega-\alpha-\gamma)}}$ can be made very small.

Remark in particular that since $0 < \omega < \frac{1}{4}$ and $n(n-1) \vee 2n < p < +\infty$, then the condition $\omega - \delta + \frac{n}{p} < 0$ is fulfilled. As Proposition 4.2 only involves the properties of the Lévy-type operator \mathcal{L}^α , its proof follows the same lines given in [7], Lemma 4.8. We refer to this article for the details.

With the help of Propositions 4.1 and 4.2, we go back to (4.11) and we have

$$\int_0^{s_0} I_s ds \leq c \int_0^{s_0} (I_{s,1} + I_{s,2}) ds \leq c(\eta_1 + \eta_2) r^{\omega-\alpha-\gamma}.$$

Using the initial concentration condition (4.1) one gets:

$$\begin{aligned} \int_{\mathbb{R}^n} |x - x(s_0)|^\omega |\psi(s_0, x)| dx &\leq (\zeta r)^{\omega-\gamma} + 2c(\eta_1 + \eta_2) r^{\omega-\alpha-\gamma} s_0 \\ &\leq \left((\zeta r)^\alpha + 2c \frac{\alpha}{\omega-\gamma} (\eta_1 + \eta_2) \frac{s_0}{\zeta^{\omega-\alpha-\gamma}} \right)^{\frac{\omega-\gamma}{\alpha}} = ((\zeta r)^\alpha + K s_0)^{\frac{\omega-\gamma}{\alpha}}, \end{aligned}$$

and we want to make the quantity $K = 2c \frac{\alpha}{\omega-\gamma} (\eta_1 + \eta_2) \frac{1}{\zeta^{(\omega-\alpha-\gamma)}}$ very small. By the computations above, it is possible to choose ζ big enough in order to obtain the inequality

$$K = 2c \frac{\alpha}{\omega-\gamma} (\eta_1 + \eta_2) \frac{1}{\zeta^{(\omega-\alpha-\gamma)}} \leq \left(\frac{\alpha}{n+\gamma} \right) \bar{c}_1 \times \mathfrak{c}, \quad (4.34)$$

where the constant \bar{c}_1 is related to the hypotheses (2.2) assumed for the Lévy operator \mathcal{L} and where the constant $\mathfrak{c} := \frac{v_n(5^n-1) - \sqrt{2v_n}5^{n-\omega}}{2 \times 5^{n+\alpha}}$ is chosen as in the proof of Theorem 10 of [7] to handle the height condition (see also the remarks below). We finally obtain the following inequality for the concentration condition with an appropriate control of the constant K :

$$\int_{\mathbb{R}^n} |x - x(s_0)|^\omega \psi(s_0, x) dx \leq ((\zeta r)^\alpha + K s_0)^{\frac{\omega-\gamma}{\alpha}}.$$

This concludes the study of the concentration condition.

2) Height condition and L^1 estimate

The height condition only involves the operator \mathcal{L}^α , independently of the drift, since we are led to investigate the time evolution of the supremum norm in space which precisely annihilates the transport term.

This contribution can readily be analyzed following the proof of Theorem 10 in [7] which precisely yields estimate (4.8). The L^1 estimate of equation (4.9) then follows from a direct optimization over the parameter D writing

$$\begin{aligned} \int_{\mathbb{R}^n} |\psi(s_0, x)| dx &= \int_{\{|x-x(s_0)| < D\}} |\psi(s_0, x)| dx + \int_{\{|x-x(s_0)| \geq D\}} |\psi(s_0, x)| dx \\ &\leq v_n D^n \|\psi(s_0, \cdot)\|_{L^\infty} + D^{-\omega} \int_{\mathbb{R}^n} |\psi(s_0, x)| |x - x(s_0)|^\omega dx. \end{aligned}$$

Theorem 8 is now completely proven. ■

4.2 $L^{p'}$ control and Iteration

Once we have a good control over the quantities $\|\psi(s_0, \cdot)\|_{L^1}$ and $\|\psi(s_0, \cdot)\|_{L^\infty}$ (from (4.9) and (4.8)), by interpolation we obtain the following bound

$$\|\psi(s_0, \cdot)\|_{L^{p'}} \leq \|\psi(s_0, \cdot)\|_{L^1}^{\frac{1}{p'}} \|\psi(s_0, \cdot)\|_{L^\infty}^{1-\frac{1}{p'}} \leq C \left[((\zeta r)^\alpha + K s_0)^\alpha \right]^{-n+\frac{n}{p'}-\gamma}.$$

We thus see with Theorem 8 that it is possible to control the $L^{p'}$ norm of the molecules ψ from 0 to a small time s_0 , and applying inductively the same arguments we can extend the control from time s_0 to time s_1 with a small increment $s_1 - s_0 \sim r^\alpha$. Now we can see that the smallness of the parameter r and of the time increments $s_0, s_1 - s_0, \dots, s_N - s_{N-1}$ can be compensated by the number of iterations N : fix a small $0 < r < 1$ and iterate as explained before. Since each small time increment $s_0, s_1 - s_0, \dots, s_N - s_{N-1}$ has order ϵr^α , we have $s_N \sim N \epsilon r^\alpha$. Thus, we will stop the iterations as soon as $N \epsilon r^\alpha \geq T_0$.

The number of iterations $N = N(r)$ will depend on the smallness of the molecule's size r , and it is enough to consider $N(r) \sim \frac{T_0}{\epsilon r^\alpha}$ in order to obtain this lower bound for $N(r)$. Proceeding this way we will obtain $\|\psi(s_N, \cdot)\|_{L^{p'}} \leq C T_0^{-n+\frac{n}{p'}-\gamma} < +\infty$, for all molecules of size r . Observe that once this estimate is available, for larger times it is enough to apply the maximum principle.

Finally, and for all $r > 0$, we obtain after a time T_0 a $L^{p'}$ control for small molecules and we finish the proof of the Theorem 7. ■

A Appendix

We prove in this section Lemmas 4.1 and 4.2.

Proof of Lemma 4.1. Using the definition of $\overline{A_{[\theta, \rho]}}$ given in (4.10), and for $1 < p < +\infty$ we write

$$\|A_{[\theta]}(t-s, \cdot) - \overline{A_{[\theta, \rho]}}(t-s, x(s))\|_{L^p(B_\rho)}^p = \int_{B_\rho} \left| A_{[\theta]}(t-s, x) - \int_{\mathbb{R}^n} A_{[\theta]}(t-s, x(s)-y) \varphi_\rho(y) dy \right|^p dx$$

$$\begin{aligned}
&\leq 2^{p-1} \left(\int_{B_\rho} \left| A_{[\theta]}(t-s, x) - \int_{\mathbb{R}^n} A_{[\theta]}(t-s, x-y) \varphi_\rho(y) dy \right|^p dx \right. \\
&\quad \left. + \int_{B_\rho} \left| \int_{\mathbb{R}^n} (A_{[\theta]}(t-s, x(s)-y) - A_{[\theta]}(t-s, x-y)) \varphi_\rho(y) dy \right|^p dx \right) \\
&\leq 2^{p-1} \left(\int_{B_\rho} \int_{\mathbb{R}^n} |A_{[\theta]}(t-s, x) - A_{[\theta]}(t-s, x-y)|^p |\varphi_\rho(y)| dy dx \right. \\
&\quad \left. + \int_{B_\rho} \left| \int_{\mathbb{R}^n} A_{[\theta]}(t-s, y) (\varphi_\rho(x-y) - \varphi_\rho(x(s)-y)) dy \right|^p dx \right), \tag{A.1}
\end{aligned}$$

using the Jensen inequality for the last bound. Since $\int_{\mathbb{R}^n} (\varphi_\rho(x-y) - \varphi_\rho(x(s)-y)) dy = 0$ and $\|\varphi_\rho\|_{L^1(\mathbb{R}^n)} = 1$, we obtain

$$\begin{aligned}
&\left| \int_{\mathbb{R}^n} A_{[\theta]}(t-s, y) (\varphi_\rho(x-y) - \varphi_\rho(x(s)-y)) dy \right|^p = \\
&\left| \int_{\mathbb{R}^n} (A_{[\theta]}(t-s, y) - A_{[\theta]}(t-s, x)) (\varphi_\rho(x-y) - \varphi_\rho(x(s)-y)) dy \right|^p \\
&\leq 2^{p-1} \int_{\mathbb{R}^n} |A_{[\theta]}(t-s, y) - A_{[\theta]}(t-s, x)|^p |\varphi_\rho(x-y) - \varphi_\rho(x(s)-y)| dy.
\end{aligned}$$

Plugging this estimate in (A.1) yields:

$$\begin{aligned}
\|A_{[\theta]}(t-s, \cdot) - \overline{A_{[\theta], \rho}}(t-s, \cdot)\|_{L^p(B_\rho)}^p &\leq 2^{p-1} \left(\int_{B_\rho} \int_{\mathbb{R}^n} |A_{[\theta]}(t-s, x) - A_{[\theta]}(t-s, x-y)|^p |\varphi_\rho(y)| dy dx \right. \\
&\quad \left. + 2^{p-1} \int_{B_\rho} \int_{\mathbb{R}^n} |A_{[\theta]}(t-s, y) - A_{[\theta]}(t-s, x)|^p (\varphi_\rho(x-y) + \varphi_\rho(x(s)-y)) dy dx \right).
\end{aligned}$$

Now if we consider a small fixed parameter s such that $0 < sp < 1$ we can write

$$\begin{aligned}
&\|A_{[\theta]}(t-s, \cdot) - \overline{A_{[\theta], \rho}}(t-s, \cdot)\|_{L^p(B_\rho)}^p \\
&\leq 2^{p-1} \left(\int_{B_\rho} \int_{\mathbb{R}^n} \frac{|A_{[\theta]}(t-s, x) - A_{[\theta]}(t-s, x-y)|^p}{|y|^{n+sp}} |y|^{n+sp} |\varphi_\rho(y)| dy dx \right. \\
&\quad \left. + \int_{B_\rho} \int_{\mathbb{R}^n} \frac{|A_{[\theta]}(t-s, y) - A_{[\theta]}(t-s, x)|^p}{|x-y|^{n+sp}} |x-y|^{n+sp} (\varphi_\rho(x-y) + \varphi_\rho(x(s)-y)) dy dx \right).
\end{aligned}$$

But, since $x \in B_\rho$ and $y \in B_\rho$ due to the support properties of φ_ρ in the first integral, and $|x-y| \leq \rho$, $|x(s)-y| \leq 2\rho$ for the second one, we get that

$$|y|^{n+sp} |\varphi_\rho(y)| \leq C \rho^{n+sp} \frac{\|\varphi\|_{L^\infty}}{\rho^n} \leq C \rho^{sp} \|\varphi\|_{L^\infty},$$

and $|x-y|^{n+sp} (\varphi_\rho(x-y) + \varphi_\rho(x(s)-y)) \leq C \rho^{n+sp} \frac{\|\varphi\|_{L^\infty}}{\rho^n} \leq C \rho^{sp} \|\varphi\|_{L^\infty}$. Thus:

$$\|A_{[\theta]}(t-s, \cdot) - \overline{A_{[\theta], \rho}}(t-s, \cdot)\|_{L^p(B_\rho)}^p \leq C \rho^{sp} \|\varphi\|_{L^\infty} \int_{\mathbb{R}^n} \int_{\mathbb{R}^n} \frac{|A_{[\theta]}(t-s, x) - A_{[\theta]}(t-s, y)|^p}{|x-y|^{n+sp}} dy dx.$$

With the definition of Besov spaces given in (2.4) we have

$$\|A_{[\theta]}(t-s, \cdot) - \overline{A_{[\theta], \rho}}(t-s, x(s))\|_{L^p(B_\rho)} \leq C \rho^s \|A_{[\theta]}(t-s, \cdot)\|_{\dot{B}_p^{s,p}(\mathbb{R}^n)}.$$

To obtain Lemma 4.1 it is enough to replace s by $\frac{\alpha}{p}$ and to recover inequalities (4.17) and (4.18) we replace s by $\frac{\alpha}{p} + \eta$ and by $\frac{\alpha}{p} - \eta$ respectively. ■

Proof of Lemma 4.2. The proof of this lemma follows almost the same lines than the previous one. Indeed, recalling that we now have $x \in B_{2^k \rho}$, we derive in the same manner that for $1 < p < +\infty$ and $0 < s < 1$:

$$\begin{aligned} & \|A_{[\theta]}(t-s, \cdot) - \overline{A_{[\theta, \rho]}}(t-s, x(s))\|_{L^p(B_{2^k \rho})}^p \\ & \leq C \int_{B_{2^k \rho}} \int_{\mathbb{R}^n} \frac{|A_{[\theta]}(t-s, x) - A_{[\theta]}(t-s, y)|^p}{|x-y|^{n+sp}} |2^k \rho|^{n+sp} \frac{\|\varphi\|_{L^\infty}}{\rho^n} dy dx. \end{aligned}$$

We thus obtain

$$\|A_{[\theta]}(t-s, \cdot) - \overline{A_{[\theta, \rho]}}(t-s, \cdot)\|_{L^p(B_{2^k \rho})} \leq C(2^k \rho)^s \times 2^{\frac{kn}{p}} \times \|A_{[\theta]}(t-s, \cdot)\|_{\dot{B}_p^{s,p}(\mathbb{R}^n)}.$$

Again, to obtain Lemma 4.2 it is enough to replace s by $\frac{\alpha}{p}$. To recover inequalities (4.27) and (4.28) we replace s by $\frac{\alpha}{p} + \eta$ and by $\frac{\alpha}{p} - \eta$ respectively. ■

Acknowledgments

We kindly acknowledge the two anonymous referees for their careful reading and comments which helped improving the manuscript.

For the second author, the article was prepared within the framework of a subsidy granted to the HSE by the Government of the Russian Federation for the implementation of the Global Competitiveness Program.
