enantioselective organocatalysis

Abstract In this feature article, we present a general perspective of our research program aimed towards the preparation of polycyclic heterocycles by the means of enantioselective organocatalytic multicomponent reactions. Guidelines for reaction design, including the selection of substrates and organocatalysts are discussed. For all transformations, scope and limitations will be presented, along with post-functionalization to afford diversified heterocyclic scaffolds.

- 1 Introduction
- 2 Type I Products: 1,4,5,6-Tetrahydropyridines
- 3 Type II Products: 1,2,3,4-Tetrahydropyridines
- 4 Type III Products: Bridged Perhydropyridines
- 5 Conclusion and Perspective

Key words 1,3-Dicarbonyls - Enantioselectivity - Heterocycles - Michael Addition - Multicomponent Reactions - Organocatalysis

1 Introduction

Heterocycles are key synthetic targets in view of their ubiquitous presence in bioactive molecules.¹ When these molecules bear stereogenic elements, it is of utter importance to control their configuration as the stereochemical information may have a deep influence on their interaction with the biological target. In that prospect, organocatalysis² has emerged as a very powerful tool since it allows the stereoselective synthesis of a large variety of heterocyclic compounds with high enantiomeric excesses.³ Among these heterocycles, polyhydropyridines are both interesting synthetic targets and an inspiration for the development of new patterns of reactivity. Thus, many new strategies were designed following the seminal contributions of Renaud's and Gong's research groups using Brønsted acid catalysis⁴ and Hayashi's and Jørgensen's teams by applying iminium activation.⁵ When we became interested in this area of research, we hypothesized that multicomponent reactions,⁶ that is to say the initial simultaneous introduction of at least three reaction partners that will be integrated in the target product,

would be an interesting tool to efficiently prepare new enantioenriched polyhydropyridine motifs. β -Dicarbonyl compounds are generally used as pronucleophiles in the synthesis of these heterocycles and their polyfunctional nature makes them ideal substrates for multiple bond-forming transformations (MBFT's) including domino processes and multicomponent reactions.⁷

Our starting point was the combination of an α,β -unsaturated aldehyde **A**, a β -dicarbonyl **B** and a functionalized amine **C** in the presence of a chiral non-racemic organocatalyst (Scheme 1). After the initial catalyst-controlled enantioselective Michael addition that forges the first stereogenic center,⁸ the amine functionality combines with the aldehyde and the ketone of the Michael adduct **D** affording 1,4-dihydropyridine **E** with loss of two molecules of water. In 1,4-dihydropyridine **E**, each side of the dienamine motif can tautomerize to the corresponding iminium ion to deliver reactive intermediates **F** and **F'**, whose trapping by the pendant nucleophile delivers fused 1,4,5,6-tetrahydropyridines **G** (**Type I**)⁹ and 1,2,3,4-tetrahydropyridines **G'** (**Type II**), bearing two or three stereogenic centers, respectively.¹⁰ When a secondary amide group is present on the substrate, a zwitterionic intermediate **H** can then be envisaged, whose cyclization leads to the formation of bridged perhydropyridines **I** (**Type III**) incorporating up to four stereogenic carbon atoms.¹¹ Of course, for this last family of products, the order of the cyclization events can also be interchanged. In principle, all the elemental steps of the different reaction pathways (acido-basic exchanges, Michael additions, dehydrations, tautomerizations and iminium ion trappings) can be reversible. In addition to their inherent step-economic nature and high synthetic efficiency for the fast elaboration of highly complex architectures, multicomponent reactions also offer interesting opportunities in terms of efficiency and stereoselectivity. Indeed, if one or several of the bond-forming events are kinetically and/or thermodynamically favored, this could help driving the whole sequence towards the efficient

Scheme 1. General reactivity pattern for the organocatalytic multicomponent synthesis of enantioenriched heterocycles.

formation of the desired product. Moreover, for enantioselective transformations, the steps that follow the enantiodiscriminating one can prevent its reversibility, thereby avoiding the racemization of the product, which was for example already noticed in a related stepwise synthesis of 1,4-dihydropyridines.^{5b} However, two important conditions have to be respected for the design of multicomponent enantioselective transformations: (i) the third reaction partner should not interact in a deleterious way with the organocatalyst; (ii) all the steps of the sequence should occur fast enough in similar reaction conditions, which might become problematic, especially when low temperature is required to ensure good enantioselection during the Michael addition.

Complementary to scarce reports by other groups for the inclusion of β -dicarbonyls in organocatalytic enantioselective multicomponent transformations,^{7h,12} we have recently disclosed independent synthetic routes towards three families of enantioenriched heterocycles (Figure 1): pyrrololpiperazine derivatives with a 1,4,5,6-tetrahydropyridine motif (**Type I**),⁹ 1,2,3,4-tetrahydropyridines (**Type II**)¹⁰ and 2,6-diazabicyclo[2.2.2]octan-3-ones (2,6-DABCOs, **Type III**).^{11,13,14} In this Feature Article, we wish to provide the readers, with a general overview of our reaction design to help trigger new development in this area. The structure of the different reaction

partners, especially the β -dicarbonyl and the pendant nucleophile on the amine, the mode of action of the organocatalyst and the reaction conditions are among the key factors that control the chemo- and enantioselective formation of one defined product. Scope, limitations and bridging between the different patterns of reactivity will be discussed. Moreover, post-functionalizations of the products to afford structurally diverse heterocyclic scaffolds will also be presented.

2 Type I Products: 1,4,5,6-Tetrahydropyridines (Pyrrololpiperazines)

With the general reactivity pattern presented in Scheme 1 in mind, **Type I** products first appeared as the easiest synthetic targets. Indeed, tautomerization of the common intermediate **E** should favor the formation of iminium ion **F**, which exhibits higher conjugation and whose electrophilic reactive center is less hindered than in its congener **F'**. A number of similar organocatalytic sequences involving a secondary amine-catalyzed Michael addition followed by the cyclization of a pendant nucleophile, either an electron-rich aromatic ring¹⁵ or an heteroatom,¹⁶ had already been described before but in a stepwise fashion, with the requirement of a strong and/or stoichiometric acid. As the presence of this additive was likely to damage the activity of the secondary amine catalyst, we set out to find a nucleophilic moiety that could react even in the absence of an acid. Since the pyrrole ring is known to exhibit strong nucleophilicity, which is further increased when it is alkylated,¹⁷ it was selected as the third reaction partner, with the aim to trap the iminium intermediate through a Pictet-Spengler-type cyclization. Pleasingly, mixing equimolar ratios of an α -methylene β -ketoester **1** and *N*-(2-aminoethyl)pyrrole (**3**) with a 1.5-fold excess of an enal **2** in the presence of Hayashi-Jørgensen catalyst **4** delivered the expected polycyclic structure **5** (Scheme 2).^{9a} It should be noted that other classical secondary amine organocatalysts performed very poorly in this transformation and that trifluorotoluene as the solvent had an appreciable positive impact on the enantioselectivity of the reaction. The overall transformation allowed the formation of four new bonds, a tricyclic pyrrololpiperazine core and two stereogenic carbon atoms. Twenty different products with possibilities of variation

Figure 1. Families of polyheterocycles discussed in this article.

on all three reaction partners were prepared in moderate yields because of the fragility of the pyrrole unit.

Scheme 2. Pyrrolo-piperazines incorporating a 1,4,5,6-tetrahydropyridine core: previous results.^{9a}

If enantioselectivities were generally good to excellent (74-99% *ee*), there was no diastereoselectivity during the Pictet-Spengler cyclization, but this drawback was counterbalanced by the fact that the two diastereomers could generally be separated by flash chromatography. To widen the application range of this transformation, we then wished to pursue the four following directions (Scheme 3):

- Why is there no diastereoselectivity and is there a way to solve this issue?
- Is it possible to replace the alkyl or aryl group at R³ by a more functionalized one?
- Could the β-ketoester be replaced by other pronucleophiles?
- Could other bis-nucleophilic units than *N*-(2-aminoethyl)pyrroles participate in the reaction?

Scheme 3. 1,4,5,6-Tetrahydropyridines: open questions.

2.1 Diastereoselectivity of the reaction

Before studying the diastereoselectivity of the process, it was necessary to determine whether the second stereogenic carbon atom was forged under kinetic or thermodynamic control. When diastereomerically pure *cis*-**5a** was placed back in the reaction conditions in the presence of a substituted *N*-(2-aminoethyl)pyrrole **3b** (Scheme 4a), it was recovered unchanged (neither epimerization, nor cross-over product **5b**), pointing towards an irreversibility of the cyclization process. In related enantioselective Michael addition-Pictet-Spengler domino processes, an improvement of the diastereoselectivity was observed by the addition of a strong acid at the end of the reaction.^{15a,18} In the present case, treatment of **5a** as a 1.4:1 mixture of diastereomers with an acid resulted either in no evolution or in its complete degradation (Scheme 4b). Thus, diastereoselectivity in this system seems difficult to control since both faces of iminium ion intermediate are not enough differentiated by the relatively distant stereogenic carbon atom.

Scheme 4. Reversibility and diastereoselectivity in the synthesis of pyrrolo-piperazines.

2.2 Reaction with ethyl 4-oxobut-2-enoate

In our initial studies, we had used aldehydes bearing alkyl, vinyl and (hetero)aryl substituents at their β position. To broaden the synthetic usefulness of the present transformation, we became interested in the use of ethyl 4-oxobut-2-enoate **2c** (Scheme 5). Directly applying the standard multicomponent conditions or trying to alter them (use of various solvents: CH₂Cl₂, CH₃CN; reaction at room temperature; addition of benzoic acid as co-catalyst) failed to provide the expected product. We surmised that the high electrophilicity of this enal might result in side reactions with the other reaction partners. To solve this issue, we came back to a one-pot two-step process: pleasingly, if *N*-(2-aminoethyl)pyrrole (**3a**) was added after two days and the reaction mixture kept at 0 °C for an additional day, pyrrolo-piperazine **5c** was isolated in 45% yield as a ~1.2:1 diastereomeric mixture with high enantioselectivities (94% and 93% *ee* for each diastereomer, respectively).

Scheme 5. Enantioselective synthesis of pyrroloperazine **5c** from ethyl 4-oxobut-2-enoate **2c**.

2.3 More diversified Michael pronucleophiles

Our initial studies were limited to the use of β -ketoesters as pronucleophiles. However, a large variety of Michael donors have demonstrated the ability to add enantioselectively to enals activated as the corresponding iminium ions by a secondary amine catalyst.¹⁹ A certain number of these compounds of type **6a-h** were evaluated and many of them proved to be able to deliver the corresponding pyrroloperazine products **7aa-ha**, **7ad** and **7fe** at the cost of slight modifications of the standard reaction conditions (Table 1). With acetylacetone (**6a**) as the pronucleophile, a low yield of product **7aa** and only moderate enantioselectivity were obtained in the standard reaction

Table 1. Scope of various Michael donors for the enantioselective multicomponent synthesis of pyrroloperazines.^[a]

^aAll reactions were run using **6a-h** (0.200 mmol, 1 equiv), **2a,d,e** (0.300 mmol, 1.5 equiv), **3a** (0.200 mmol, 1 equiv) and catalyst **4** (0.020 mmol, 0.1 equiv) in CF₃C₆H₅ (2.5 mL) for 48 h at 0 °C. Changes from these standard reaction conditions are notified in the table. ^bYields of analytically pure isolated products (yields between brackets are those of the *cis* and *trans* diastereomers, respectively, when they could be separated). ^cEnantiomeric excesses (*ee*) were determined by HPLC analysis on a chiral stationary phase. ^dDuring optimization studies, only the *ee* of the *cis* diastereomer was determined, as both of them usually have similar values. ^eProduct purities ~90%. ^fThe diastereomers could not be separated and the diastereomeric ratios (*dr*) were determined by ¹H NMR spectroscopy analysis after purification.

Scheme 6. Use of *N*-(2-aminoethyl)indole derivative **8**.

conditions (Entry 1). However, the addition of benzoic acid as a co-catalyst proved beneficial for the product formation (Entry 2). Ultimately, replacing CF₃C₆H₅ by CH₂Cl₂ as the solvent and decreasing the reaction temperature to –10 °C delivered **7aa** with yields and enantioselectivities similar to those obtained with the β -ketoesters (Entry 3). Those optimized reaction conditions transposed efficiently to prepare **7ad** from 4-chlorocinnamaldehyde (**2d**) (Entry 4). On the contrary, cyclic diketones such as dimedone (**6b**) proved to be more challenging substrates: only moderate yields and enantioselectivities were obtained for **7ba**, and the addition of an acidic co-catalyst was deleterious (Entries 5 and 6). We have recently reported that tertiary β -ketoamides can be potent Michael donors that can add to nitroolefins under hydrogen-bonding organocatalysis with high enantio- and diastereoselectivities.²⁰ We were intrigued whether they could also participate in the multicomponent organocatalytic synthesis of pyrrollopiperazines. Both *N,N*-dimethyl and Weinreb β -ketoamides **6c** and **6d** reacted in the standard reaction conditions (Entries 7 and 8): even though both diastereomers are present in the crude reaction mixture, only the *trans* diastereomers of products **7ca** and **7da** could be obtained pure, and their enantiomeric excesses were satisfying. β -Ketothioester **6e** was also a potent pronucleophile in this transformation, but product **7ea** was formed only with a moderate enantioselectivity. The next step was to substitute the ester moiety by a sulfone or a phosphonate. Both substrates **6f** and **6g** failed to react when cinnamaldehyde (**2a**) was used as the electrophile (Entries 10 and 14). However, based on literature precedents showing that **6f** reacts preferentially with enals bearing an aliphatic group at the β position,²¹ crotonaldehyde (**2e**) was combined with **6f** and **3a** in the standard reaction conditions (Entry 11): this time, product **7fe** was obtained, but in mixture with inseparable impurities. Once again, an acidic co-catalyst was inefficient (Entry 12), but extending the reaction time somewhat improved the results (Entry 13). To finish with, 1-acetylindolin-3-ones are also known to add to enals under secondary amine catalysis.²² Our standard reaction conditions applied to substrate **6h** delivered the expected fused pentacyclic product **7ha** as an inseparable mixture of diastereomers in good yield and enantioselectivities, which could even be improved by using CH₂Cl₂ as solvent (Entries 15 and 16).

2.4 Alternative bis-nucleophilic units

The last direction we wanted to explore for the **Type I** products was the possibility to replace the pyrrole ring by other nucleophilic units. Disappointingly, our initial attempts with indole derivatives failed to provide the expected products.^{9a} We wanted to re-investigate their use and turned our attention towards more electron-rich *N*-(2-aminoethyl)indole derivative **8** (Scheme 6). When it was added to the reaction mixture after an initial organocatalytic Michael addition between **1a** and **2a**, the expected indolopiperazine **9** was obtained as its pure *trans* diastereomer in 32% yield and 85% ee after purification by flash chromatography on silica gel. Alternatively, a purification of the crude reaction mixture on neutral alumina delivered the corresponding 1,4-dihydropyridine **10** in 30% yield and 91% ee. This last result demonstrates that the Pictet-Spengler cyclization with the indole derivative is not spontaneous in the reaction conditions and requires an acidic environment, thus highlighting the unique behavior of the pyrrole ring in its ability to cyclize in acid-free conditions.

In a complementary fashion, we were interested in using heteroatom-based pendant nucleophiles instead of an electron-rich heteroaromatic ring.²³ *tert*-Butyl acetoacetate (**1a**) and cinnamaldehyde (**2a**) were combined with five different bis-nucleophiles **11a-c, 12a** in the presence of Hayashi-Jørgensen catalyst **4** (Table 2). No product formation was observed with 2-aminoethanol (**11a**) and anthranilamide (**11b**) (Entries 1 and 2).²⁴ Conversely, the use of 2-aminobenzyl alcohol (**11c**) delivered the moderately pure expected product **13c** in modest amount but with a fair enantioselectivity (Entry 3). At last, using 2-aminophenol (**12a**) resulted in a mixture of a small amount of expected **14** together with its regioisomer **15** (Entry 5).²⁵ This result was all the more interesting since, contrary to products **13c** and **14**, the new 1,2,3,4-tetrahydropyridine **15** **Type II** product bearing three contiguous stereogenic centers was formed virtually as a single diastereomer and also with excellent enantioselectivity. This discovery paved the way for further developments towards the enantioselective synthesis of this uncommon heterocyclic motif, which will be discussed in details in the following section.

Table 2. Screening of heteroatomic bis-nucleophiles for the enantioselective multicomponent synthesis of tetrahydropyridines.^[a]

Entry	Bis-nucleophile	Product 13a-c,14		Product 15	
		Yield (<i>dr</i>) ^[b]	<i>ee</i> ^[c]	Yield (<i>dr</i>) ^[b]	<i>ee</i> ^[c]
1	11a	13a : no product	-	-	-
2	11b	13b : no product	-	-	-
3	11c	13c : ~25% (1.3:1 <i>dr</i>)	88% and 90%	-	-
4	12a	14 : <10% (1.5:1 <i>dr</i>) ^[d]	n.d.	15 : 25% (>20:1 <i>dr</i>)	94%

^aAll reactions were run using **1a** (0.200 mmol, 1 equiv), **2a** (0.300 mmol, 1.5 equiv), **11a-c,12a** (0.200 mmol, 1 equiv) and catalyst **4** (0.020 mmol, 0.1 equiv) in CF₃C₆H₅ (2.5 mL) for 48 h at 0 °C. ^bYields of analytically pure isolated products and diastereomeric ratios (*dr*) determined by ¹H NMR spectroscopy analysis after purification. ^cEnantiomeric excesses were determined by HPLC analysis on a chiral stationary phase. ^dThe product could not be obtained pure.

3 Type II Products: 1,2,3,4-Tetrahydropyridines

Having observed the formation of **Type II** product **15** (Table 2), we became interested in trying to fully counterbalance the regioselectivity of the multicomponent reaction to obtain this previously unknown family of 1,2,3,4-tetrahydropyridines, exclusively. We hypothesized that the equilibrium between iminium ions **F** and **F'** and the relative stabilities of products **G** and **G'** (Scheme 1) would be key factors to reach this goal. The usual higher stability of **F** and **G** over **F'** and **G'**, respectively, can be explained by the higher delocalization of π electrons through the enaminoester. We hypothesized that replacing the ester group by a bulkier tertiary amide would create strong 1,3-allylic strain, which could outcompete the stabilization energy brought about by the conjugation, thereby forcing the amide group to turn outside of the plane.^{20,26} Pleasingly, when *tert*-butyl acetoacetate (**1a**) was replaced by the corresponding Weinreb β -ketoamide **6d**, only 1,2,3,4-tetrahydropyridine **16a** was obtained in modest yield, as a single diastereomer (Scheme 7). Thereafter, a thorough optimization of the reaction conditions was conducted pointing

Scheme 7. 1,2,3,4-Tetrahydropyridines: control of regio- and stereoselectivity with Weinreb β -ketoamide **6d**.¹⁰

towards: (i) an increase of the catalyst loading to 20 mol%; (ii) the use of benzoic acid as co-catalyst; (iii) the replacement of trifluorotoluene by CH₂Cl₂; (iv) the increase of the temperature to 10 °C and of the reaction time to 60 h.¹⁰ This new reaction was then exemplified on a variety of cinnamaldehyde derivatives **2** and functionalized 2-aminophenols **12** (Scheme 8). Products **16**, in which four new bonds and three stereogenic centers are installed in a single synthetic operation were obtained with moderate yields, but high stereoselectivities. Variations on the β -ketoamide were less straightforward since

Scheme 8. 1,2,3,4-Tetrahydropyridines: previous results.¹⁰

the replacement of Weinreb amide **6d** by the less activated *N,N*-dimethyl analogue **6c** delivered the expected product with lower yield but preserved stereoselectivities. After our initial studies, we foresaw two different directions to increase the synthetic usefulness of this transformation (Scheme 9):

- Is it possible to replace the methyl group on the ketone by other substituents?
- Are the different functionalities of the product (enamine, aminal and amide) amenable to post-functionalization to reach more diversified scaffolds?

Scheme 9. 1,2,3,4-Tetrahydropyridines: open questions.

3.1 Use of more diverse β -ketoamides

At first, we screened γ -alkyl- and γ -aryl- β -ketoamides **17a-d**, which we had used in our organocatalytic Michael addition to nitroolefins,^{20a} in the standard reaction conditions to prepare the corresponding 1,2,3,4-tetrahydropyridines (Figure 2). Unfortunately, all of them proved to be not reactive enough and the expected products were obtained with less than 15% yields. To try to overcome this issue, γ -bromo-ketoamide **17d** was prepared²⁷ with the hope that the inductive withdrawing effect of the bromine atom would render the activation of the β -ketoamide easier. Moreover, it could also serve as a handle for post-functionalization. However, once again, only low conversion into the 1,2,3,4-tetrahydropyridine was observed.

Figure 2. Unsuitable β -ketoamide substrates **17a-d**.

The only other option left was to modify the amide moiety, by replacing the *N*-methoxy-*N*-methyl unit by a group with stronger electron-withdrawing ability and/or that could provide a better interaction with the catalyst. Following the work of Jørgensen and co-workers on the Michael addition of 1,3-dicarbonyls bearing an oxazolidinone to nitroolefins,²⁸ we turned our attention towards the use of the pyrrolidinone derivative **20**. It was easily prepared by the thermal decomposition of 2,2,6-trimethyl-4*H*-1,3-dioxin-4-one **18**, followed by the trapping of the intermediate α -oxoketene by pyrrolidinone **19**.²⁹ This new substrate was then exposed to the standard conditions for the multicomponent synthesis of 1,2,3,4-tetrahydropyridines, resulting in a complex mixture including regioisomeric products **21** and **22**. From this result, we can see that it seems to be a balance between reactivity and regioselectivity as β -dicarbonyl compounds with a more acidic α position are more easily

activated in the catalytic conditions but also tend to provide the 1,4,5,6-tetrahydropyridine regioisomer.

Scheme 10. Pyrrolidinone-derived β -ketoamide **20**: synthesis and use in the multicomponent reaction.

3.2 Post-functionalization on the products

The major structural originality of 1,2,3,4-tetrahydropyridines compared to the products obtained in other methodologies targeting enantioenriched polyhydropyridines, is the presence of the enamine function. In our previous studies, we showed that both its reduction with dihydrogen in the presence of a catalytic amount of Pd/C and its isomerization into the corresponding iminium ion under Sc(OTf)₃-catalysis and the subsequent trapping with a potassium alcyntriyltrifluoroborate proceeded with good yields and good preservation of the enantiomeric excesses.¹⁰ To study the reactivity on other positions of the product, the reduction was repeated on enamine **16a** to furnish **23** (Scheme 11). In the presence of scandium (III) triflate as a

Scheme 11. Sequential post-functionalization of 1,2,3,4-tetrahydropyridines **16a**

catalytic Lewis acid, potassium phenylethynyltrifluoroborate (**24**) could then add to the transient iminium ion obtained by the opening of amina **23** to furnish compound **25** in moderate yield but as a single diastereomer.³⁰ Unfortunately, all attempts to have the Weinreb amide functionalities of **16a**, **23** or **25** being reduced by treatment with metal hydrides did not meet with success, since either no conversion or extensive degradation was observed.

Another possibility to valorize the 1,2,3,4-tetrahydropyridines is to combine two multicomponent reactions sequentially to attain extremely high molecular complexity in a very short synthetic sequence.³¹ The three-component reaction of enamines with in-situ generated 2-azadienes has been known as the Povarov reaction.³² Combining enamine **16a** with ethyl glyoxylate (**26**) and *p*-toluidine (**27**) in the presence of a catalytic amount of Sc(OTf)₃ triggered the cycloaddition process to afford the expected product **28** in good yield (Scheme 12). Pleasingly, the two new stereogenic centers at the ring junction were installed in a *cis* relationship with complete diastereoselectivity. On the opposite, there was no control of the stereogenic center α to the ester functionality, presumably because the intermediate imine was formed as a mixture of (*E*) and (*Z*) diastereomers. All in all, the enantioenriched fused pentacyclic scaffold **28** has been elaborated in only two steps from five very simple starting materials.

3.3 Attempts of four-component reaction

Having post-functionalized the enamine moiety of 1,2,3,4-tetrahydropyridines with potassium organotrifluoroborate **24**, we also became intrigued by the possibility to integrate it directly in the multicomponent reaction (Table 3).

Scheme 12. Post-functionalization of 1,2,3,4-tetrahydropyridine **16a** by a Povarov reaction.

4-Fluorocinnamaldehyde **2f** was selected as Michael acceptor to allow an easy identification of three- and four-component products **29** and **30** by ¹⁹F NMR in the potentially complex crude reaction mixture.³³ At first, we could show that potassium phenylethynyltrifluoroborate **24** does not interfere with the initial organocatalytic process since three-component product **29** was formed in 82% NMR yield but four-component product **30** could not be observed in the crude reaction mixture (Entry 1).³⁴ Lewis acids were then evaluated as co-catalysts to help in the tautomerization process required to generate and trap the iminium ion. The development of such a transformation would represent a unique dually-catalyzed four-component reaction.³⁵ Sc(OTf)₃ had only a limited influence since it decreased the yield of **29** but did not trigger the formation of **30** (Entry 2). On the contrary, with ZrCl₄ and NbCl₅, small amounts (~20% yields) of four-component product **30** could be observed, unfortunately as racemic mixtures (Entries 3 and 4). The replacement of the Lewis acid with a Rh complex was also inefficient (Entry 5).

Table 3. Attempts of synthesis of tetrasubstituted piperidines by a dually-catalyzed four-component reaction.^[a]

Entry	Metal catalyst	Product 30		
		NMR Yield ^[b]	NMR Yield ^[b]	ee ^[c]
1	none	82%	no product	-
2	Sc(OTf) ₃	54%	no product	-
3	ZrCl ₄	4%	21%	0%
4	NbCl ₅	no product	20%	0%
5	[Rh(cod)Cl] ₂ ^[d]	47%	no product	-

^aAll reactions were run using **6d** (0.200 mmol, 1 equiv), **2f** (0.300 mmol, 1.5 equiv), **12a** (0.200 mmol, 1 equiv), **23** (0.300 mmol, 1.5 equiv), catalyst **4** (0.020 mmol, 0.1 equiv) PhCO₂H (0.040 mmol, 0.2 equiv) and the metal catalyst (0.010 mmol, 10 mol%) in CH₂Cl₂ (2.5 mL) for 40 h at 25 °C. ^bNMR yields of products **29** and **30** were determined by ¹⁹F NMR spectroscopy analysis of the crude reaction mixture. ^cEnantiomeric excesses were determined by HPLC analysis on a chiral stationary phase. ^d5 mol% of metal catalyst were used.

4 Type III Products: Bridged Perhydropyridines (2,6-DABCOs)

A careful study of the structure of 1,2,3,4-tetrahydropyridines presented in the previous section highlights the presence of the enamine moiety that could interconvert with the corresponding iminium ion and of an inert tertiary amide. Replacing the latter one by a secondary amide would add another nucleophilic position and a cyclization onto the electrophilic iminium ion could be envisioned, delivering bridged perhydropyridines as **Type III** products (Scheme 1). Relying on our studies on the addition of cyclic secondary β -ketoamides to α,β -unsaturated ketones and aldehydes under bifunctional hydrogen-bonding organocatalysis,^{36,37} we studied the possibility to add a bis-nucleophilic species to these reaction conditions. Pleasingly, mixing cyclic secondary β -ketoamides **31** with acrolein (**32**) and aminophenols **12** in the presence of bifunctional thiourea catalyst **33**³⁸ delivered chemoselectively bridged perhydropyridines **34** (Scheme 13).^{11a} Because of their resemblance with DABCO, but with the nitrogen atoms not located on the bridgehead positions, we decided to call these compounds 2,6-DABCOs.

Scheme 13. Bridged perhydropyridines (2,6-DABCOs): previous results.^{11a}

During the development of this transformation, we also uncovered the following important parameters for its success:

- A strongly electron-withdrawing group is required on the β -ketoamide's nitrogen atom, such as a sulfonyl group, to ensure both productivity and enantioselectivity. In addition to this, the reaction with acyclic pronucleophiles is poorly enantioselective.

- The structure of the aminophenols has a strong influence on the enantioselectivity of the reaction. Moreover, they are the only suitable bis-nucleophiles as free or mono-protected phenylene diamine resulted in complete degradation, whereas 2-aminobenzyl alcohol (**11c**) or salicylic acid yielded to trace amounts of the desired products.
- Other enals than acrolein (**32**) perform very poorly in the multicomponent reaction: low yield of product was obtained with methacrolein, while crotonaldehyde delivered virtually racemic product.
- 4 Å molecular sieves are required to attain high levels of enantioselectivity, presumably by trapping the water produced during the course of the reaction.

In view of the intriguing structure of these products, but also the limitations in terms of substrate diversity revealed by the scope study, we deemed it interesting to proceed to more detailed studies in the following directions (Scheme 14):

- Could β -substituted enals participate in this transformations, possibly by modifying the other substrates and the mode of activation of the organocatalyst?
- Can we envisage to get rid of the phenol moiety on the aniline, to replace the final iminium ion trapping by a tautomerization into the corresponding enamine?
- Could the synthetic potential of the reaction be increased by taking advantage of the reactivities of the amino functionalities?
- Is it possible to cleave the sulfonyl group on the product, whose presence on the β -ketoamide substrate is essential for the success of the transformation?

Scheme 14. Bridged perhydropyridines (2,6-DABCOs): open questions.

4.1 Introduction of β -substituted enals

Given the results obtained for the preparation of **Type II** products from α -methylene tertiary β -ketoamides and cinnamaldehyde derivatives with a secondary amine as catalyst (Scheme 8), we hypothesized that applying the very same reaction conditions to the corresponding secondary amides might be an interesting entry to expand the substrate scope of 2,6-DABCO synthesis (Scheme 15). More specifically, acyclic *N*-tosyl secondary β -ketoamide **35** could be introduced directly in the reaction conditions used to prepare the **Type II** products, resulting in the production of the expected 2,6-DABCOs **36a-c** with high diastereoselectivities but only moderate enantiomeric excesses.³⁹

Scheme 15. Synthesis of 2,6-DABCOs under iminium ion activation.

4.2 Tautomerization into the enamine

Initially, the aromatic hydroxyl functionality appeared as an essential structural feature to observe the formation of the 2,6-DABCO products. In subsequent studies, we wanted to investigate what is happening in its absence, especially whether the iminium ion **J** could tautomerize into a stable tetrasubstituted enamine **K**, when no nucleophile is present to trap it (Scheme 16). The presence of an additional substituent (R) on the enamine might be useful to increase its stability.

Scheme 16. Working hypothesis for the tautomerization of the iminium ion **J** into the enamine **K**.

To test this hypothesis, we needed at first to be able to prepare the corresponding γ -substituted β -ketoamides, which had never been described in the literature before and represent a real synthetic challenge because of their sensibility to a variety of acidic or basic reaction conditions. The γ -alkylation of substrate **31a** would require the intermediate preparation of a tris-anion before adding an alkylating agent, 4-fluorobenzyl bromide (**37**), which would react with the least stabilized anion (Scheme 17). Unfortunately, all our attempts to obtain product **38** failed because of competing α -alkylation and degradation processes. An alternative pathway would go through a γ -aldolization-crotonization sequence followed by the reduction of the carbon-carbon double bond.⁴⁰ Alkenylation of **31a** with 4-chlorobenzaldehyde (**39**) proceeded efficiently and

stereoselectively but attempts to reduce enone **40** into **41** either by catalytic hydrogenation or conjugate hydride addition resulted into complex reaction mixtures. Fortunately, γ -functionalization could eventually be attained by the bromination of **31a** in classical conditions, with compound **42** being obtained as a 1:1 mixture of diastereomers.

Scheme 17. Preparation of γ -substituted β -ketoamides.

Substrate **42** was then evaluated in the multicomponent enantioselective synthesis of 2,6-DABCOs (Scheme 18). At first, aniline (**43**) was tested as the third reaction partner in the reaction with **42** to try to obtain enamine product **44**. Unfortunately the bromine atom did not seem to bring enough stability to the enamine and a complete degradation of the reaction mixture was observed. On the opposite, γ -bromo- β -ketoamide revealed itself as a potent pronucleophile in the traditional 2,6-DABCO synthesis with 2-aminophenol (**12a**). In this case, product **45** was obtained in 50% yield as a single diastereomer and with 39% *ee*.⁴¹ Even though, this level of enantioselectivity is not high enough in a synthetic context, it indicates that kinetic resolution can occur to some extent during the multicomponent organocatalytic process. In addition to this, when γ,δ -unsaturated β -ketoamide **40** was placed in the reaction conditions, no 2,6-DABCO product could be observed (not depicted).

Scheme 18. Synthesis of 2,6-DABCO from γ -bromo- β -ketoamide **42**.

4.3 Post-functionalization of the products

In our seminal publication,^{11a} we had shown that the *N,O*-aminal functionality of the 2,6-DABCO could be re-opened in the presence of a Lewis acid such as boron trifluoride etherate and the resulting iminium ion could be trapped with a potassium alkynyltrifluoroborate. We repeated those reaction conditions by combining **34a** and **24** to verify that the enantiopurity of the product is maintained during this post-functionalization (Scheme 19). Pleasingly, the addition product **46** was isolated in 59% yield with only a minor erosion of the enantiomeric excess from 94% to 86%.

Scheme 19. Post-functionalization of 2,6-DABCO **34a**.

Other nucleophiles were also evaluated to intercept the transient iminium ion. Neither allyltrimethylsilane nor hydride sources such as triethylsilane, sodium borohydride or Hantzsch ester showed reactivity. On the contrary, complete degradation of the starting material was observed with trimethylsilyl cyanide. We also hypothesized that it would be possible to perform an insertion reaction in the C-O bond of the *N,O*-aminal. Indeed, the reaction of **34a** with (2,6-dimethylphenyl)isocyanide (**47**) afforded imidate **48** with good yield and complete retention of the stereochemical information. Because isocyanides are among the most popular partners in multicomponent reactions,⁴² an attempt was made to introduce **47** directly in the reaction conditions used to produce the 2,6-DABCOs. Unfortunately, it behaved only as a spectator since no four-component coupling could be found but instead the reaction proceeded as usual to furnish the three-component product.

4.4 Cleavage of the sulfonyl group

To finish our study, we wanted to explore the possibility to cleave the sulfonyl group on the 2,6-DABCO products. Indeed, this group is absolutely required to obtain high yields and stereoselectivities and being able to remove it would significantly expand the synthetic potential of the method. Unfortunately, applying classical deprotection conditions for a tosyl group on the nitrogen atom of an amide (either sodium naphthalenide or TBAF) to **34a** resulted in the complete degradation of the starting material. Surmising that the labile *N,O*-aminal was responsible for this failure, the first deprotection conditions were attempted again on compound **46** (Scheme 20). This time, the cleavage occurred smoothly and deprotected 2,6-DABCO **49** could be isolated in 48% yield without any change in the enantiomeric excess. A solution to circumvent the problems encountered during the deprotection could be to replace the tosyl group by a 4-nosyl unit, which could be cleaved in milder reaction conditions.

Scheme 20. Deprotection of the tosyl group.

Moreover, the corresponding *N*-nosyl- β -ketoamides such as **50** had already been used in an independent study to access enantioenriched glutarimides by coupling them with α,β -unsaturated acyl cyanides.^{36e} Notably, the stronger electron-withdrawing effect of the 4-nosyl group also had a positive influence on the stereoselectivity of the reaction. When **50** was placed in the standard reaction conditions, the expected 2,6-DABCO **51** was formed in good yield and very high diastereoselectivity but with only 59% ee (Scheme 23). This low enantioselectivity combined with issues of solubility and stability of the product led us to abandon this direction.

Scheme 21. Synthesis of *N*-(4-nosyl)-2,6-DABCO **51**.

5 Conclusion and Perspective

As a conclusion, in this Feature Article, we have thoroughly discussed all our recent work on the enantioselective preparation of nitrogen-containing six-membered heterocycles from very simple starting materials by the introduction of organocatalysts in multicomponent reactions. The general reaction scheme proceeds from a Michael donor, a Michael acceptor and a third component containing a primary amine, which will be able to cross-link the diverse carbonyl functionalities present on the two other partners after the initial

Table 4. General summary of reactions parameters for the three families of organocatalytic enantioselective multicomponent reactions (✓ = suitable and efficient; − = moderately efficient and/or selective; ✗ = not suitable).

Family of products	1,4,5,6-Tetrahydropyridines Type I	1,2,3,4-Tetrahydropyridines Type II	Bridged Perhydropyridines Type III
Michael donor	✓ open-chain α-methylene β-ketoesters and diketones ✗ cyclic diketones − α-methylene β-ketoamides (reduced yields) − α-methylene β-keto-thioesters (reduced <i>ee</i>) ✓ 1-acetylindolin-3-ones	− open-chain α-methylene β-ketoesters (mixture) ✓ open-chain α-methylene Weinreb β-ketoamides − open-chain α-methylene β-ketoamides (reduced yields)	✓ cyclic β-ketoamides with a strongly electron withdrawing group − open-chain α-methylene Weinreb β-ketoamides (reduced <i>ee</i>)
Michael acceptor	✓ β-arylenals − β-alkylenals (reduced yields) − ethyl 4-oxobut-2-enoate (reduced yields)	✓ β-arylenals − β-alkylenals (reduced yields)	✓ acrolein − methacrolein (reduced yield) ✗ crotonaldehyde (racemic) − β-alkylenals (reduced <i>ee</i>)
Third component	✓ <i>N</i> -(2-aminoethyl)pyrroles − <i>N</i> -(2-aminoethyl)indoles (acid required) ✗ 2-aminoethanol ✗ anthranilamide − 2-aminobenzyl alcohol (reduced yield) ✓ 2-aminoethylphenol − 2-aminophenol (mixture)	✓ 2-aminophenols	✓ 2-aminophenols ✗ phenylene diamine ✗ anthranilic acid
Organocatalyst	Iminium activation (catalyst 4). Addition of BzOH is sometimes useful.	Iminium activation (catalyst 4), in the presence of BzOH as co-catalyst.	Bifunctional hydrogen-bonding (catalyst 34) for acrolein. Iminium activation (catalyst 4) for aromatic enals.
Results	✓ good yields ✗ no diastereoselectivities ✓ good enantioselectivities	− moderate yields ✓ high diastereoselectivity ✓ good enantioselectivities	✓ good yields ✓ good diastereoselectivities − moderate to good enantioselectivities

enantioselective Michael addition. Three main families of product were obtained: 1,4,5,6-tetrahydropyridines, 1,2,3,4-tetrahydropyridines and bridged perhydropyridines. The main required features of the substrates for each family of products, along with the subsequent choice of the suitable organocatalyst, are summarized in Table 4.

Beyond the potential interest of the present methods to prepare previously unknown polyheterocyclic scaffolds, we believe that the main input of our work is to provide pieces of evidence that organocatalysis, because of its high functional compatibility, can develop as a general and efficient tool to effect organic transformations in complex reaction media with excellent chemo- and stereoselectivities.

Starting Materials

- Unless specified, commercial reagents and solvents were used as received.
- Except the new substrates, which are described below, all β -ketoamides were prepared according to known literature procedures.^{11a,20a,29b}
- Acrolein and (*E*)-cinnamaldehyde were distilled just prior to use.
- Catalyst **4** was purchased from Sigma-Aldrich and catalyst **33** from Strem.
- Crushed 4Å molecular sieves was stored in an oven at 110 °C.
- BF₃·OEt₂ was refluxed on CaH₂ and distilled prior to use.
- Potassium phenylethynyltrifluoroborate **24** was prepared according to known literature procedure.⁴³
- CH₂Cl₂, THF and toluene were dried using a M-Braun SPS-800 system. Other solvents (α,α,α -trifluorotoluene, CH₃CN, CHCl₃, MeOH and AcOH) were purchased in anhydrous quality and used without further drying.

Instrumentation and Analyses

- Analytical thin layer chromatography (TLC) was performed on silica gel 60 F254 aluminum plates (Macherey-Nagel) containing a 254 nm fluorescent indicator. TLC plates were visualized by exposure to short wave ultraviolet light (254 nm) and to anisaldehyde (2.5 mL of *p*-anisaldehyde, 3 mL of concentrated H₂SO₄ and 1.5 mL of AcOH in 100 mL of EtOH) or vanillin (2 g of vanillin and 4 mL of concentrated H₂SO₄ in 100 mL of EtOH) followed by heating.
- Flash column chromatography was performed using silica gel (35–70 μ m, Acros or 35–70 μ m, Macherey-Nagel) and basic Al₂O₃ (Macherey-Nagel)
- Proton nuclear magnetic resonance (¹H NMR) spectra were recorded with a Bruker AV 400 spectrometer. Proton chemical shifts are reported in parts per million (δ scale), and are referenced using residual protium in the NMR solvent (CDCl₃: δ 7.26 (CHCl₃) or d⁶-DMSO: δ 2.50 (d⁵-DMSO)). Data are reported as follows: chemical shift (multiplicity (s = singlet, br s = broad singlet, d = doublet, t = triplet, q = quadruplet, quint = quintuplet, sept = septuplet, m = multiplet), coupling constant(s) (Hz), integration).
- Carbon-13 nuclear magnetic resonance (¹³C NMR: CPD and DEPT-135) spectra were recorded with Bruker AV 300 or AV 400 spectrometers. Carbon chemical shifts are reported in parts per million (δ scale), and are referenced using the carbon resonances of the solvent (δ 77.16 (CHCl₃) or d⁶-DMSO: δ 39.53 (d⁶-DMSO)). Data are reported as follows: chemical shift (CH_n where n is the number of hydrogen atoms linked to the carbon atom).
- Fluorine-19 nuclear magnetic resonance (¹⁹F NMR) spectra were recorded with Bruker an AV 400 spectrometer. Fluorine chemical shifts are reported in parts per million (δ scale), and are referenced using 4-fluorobenzene as an added internal standard (δ –113.15).

- High resolution mass spectra (HRMS) were recorded on a Waters Synapt G2 HDMS apparatus using a positive electrospray (ESI) ionization source.
- HPLC analyses for the determination of enantiomeric excesses were performed on a Merck-Hitachi system equipped with Chiralcel OD-3, Chiralpak AD-H, Chiralpak AZ-H, Chiralpak IA, Chiralpak IB, Chiralpak IC, Chiralpak ID, Chiralpak IE, Chiralpak IF, Lux-Amylose-2 and Lux-Cellulose-4 columns.
- Optical Rotations were recorded on a Perkin Elmer 241 Polarimeter or an Anton Paar MCP 200 Polarimeter at 589 nm and 25 °C. Specific rotations are reported as follows: specific rotation (concentration in grams/100 mL of solution, solvent).

Procedures

General procedure A for the three-component synthesis of pyrrololipiperazines **5 and **7aa-ha,7ad,7fe**, and tetrahydropyridines **13c** and **15**:** A reaction tube was charged with (*S*)-(-)- α,α -diphenyl-2-pyrrolidinemethanol trimethylsilyl ether (**4**) (6.6 mg, 0.020 mmol, 0.1 equiv), dry α,α,α -trifluorotoluene (2.5 mL), flushed with argon and placed at 0 °C. β -ketoester **1** (0.200 mmol, 1 equiv) was then added followed by freshly distilled (*E*)- α,β -unsaturated aldehyde **2** (0.300 mmol, 1.5 equiv) and *N*-(2-aminoethyl)pyrrole **3** or substituted aniline **11c,12** (0.200 mmol, 1 equiv). After 2 days, the solution was directly purified by flash column chromatography on silica gel to provide the pyrrololipiperazines **5**, generally as two separable diastereomers or the tetrahydropyridines **13c** or **15**. For the description of products **5** (Scheme 2), see reference 9a.

General procedure B for the three-component synthesis of 1,2,3,4-tetrahydropyridines **16 and 2,6-DABCOs **36a-c**:** In a reaction tube, β -ketoamide **6c-d,35** (0.2 mmol, 1 equiv), (*E*)-cinnamaldehyde derivative **2** (0.3 mmol, 1.5 equiv), functionalized 2-aminophenol **16** (0.2 mmol, 1equiv) and benzoic acid (0.08 mmol, 0.4 equiv) were dissolved in dry CH₂Cl₂ (2 mL) under argon and placed at 10 °C. Then, (*S*)-(-)- α,α -diphenyl-2-pyrrolidinemethanol trimethylsilyl ether (**4**) (0.04 mmol, 0.2 equiv) was added to the mixture. After 60 h, around ten drops of NH₄Cl were added to the reaction mixture to deactivate the catalyst. The organic layer was then separated and concentrated under vacuum. The diastereomeric ratio of the crude product was determined by ¹H NMR. Purification by flash chromatography over silica gel yielded the corresponding three-component product. For the description of products **16** (Schemes 7 and 8), see reference 10.

General procedure C for the three-component synthesis of 2,6-DABCOs **34, **45** and **51**:** Crushed 4Å molecular sieves (200 mg) was placed in a 25-mL reaction tube equipped with a septum. Air was evacuated under high vacuum and the reaction flask heated by means of a heat gun. After coming back to room temperature, the reaction flask was filled with argon. This operation was repeated a second time. (*R,R*)-Takemoto catalyst **33** (8.3 mg, 0.020 mmol, 0.1 equiv), β -ketoamide **31** (0.200 mmol, 1 equiv) and functionalized aminophenol **12** (0.300 mmol, 1.5 equiv) were introduced in the reaction flask, which was once again flushed with argon. Dry toluene (6 mL) was added and the reaction flask was cooled to –10 °C. After 10 minutes, acrolein (**32**) (0.400 mmol, 2 equiv) was added via syringe and the reaction mixture was stirred at –10 °C for 24 h. It was then filtered over a short pad of silica gel (2 cm) that was washed with EtOAc (50 mL). Concentration under reduced pressure afforded a solid that was purified by flash column chromatography on silica gel (CH₂Cl₂/EtOAc) to provide the pure 2,6-DABCO **34**. For the description of products **34** (Scheme 13), see reference 11a.

(10*R*)-9-*tert*-butyl 10-ethyl 8-methyl-6,10,11,11a-tetrahydro-5*H*-pyrido[1,2-*a*]pyrrolo [2,1-*c*]pyrazine-9,10-dicarboxylate (5c**).** A reaction tube was charged with (*S*)-(-)- α,α -diphenyl-2-pyrrolidinemethanol trimethylsilyl ether (**4**) (6.6 mg, 0.020 mmol, 0.1 equiv), benzoic acid (4.9 mg, 0.040 mmol, 0.2 equiv), dry α,α,α -trifluorotoluene (2.5 mL), flushed with argon and placed at 0 °C. *tert*-Butyl acetoacetate (**1a**) (31.6 mg, 32.9 μ L, 0.200 mmol, 1 equiv) and (*E*)-ethyl 4-oxobut-2-enoate (**2c**) (30.8 mg, 28.9 μ L, 0.240 mmol, 1.2 equiv) were then added. After full conversion of *tert*-butyl acetoacetate (**1a**) as monitored by TLC, followed by the addition of *N*-(2-aminoethyl)pyrrole (**3a**) (22.0

mg, 21.6 μ L, 0.200 mmol, 1 equiv), the mixture was stirred at 0 °C for another 24 h. After reaction, direct purification by flash chromatography (PE/EtOAc 80:20) afforded **5c** as a mixture of diastereomers as a yellow oil (32.4 mg, 0.090 mmol, 45% yield, ~1.2:1 *dr*, 94% and 93% *ee*).

TLC (PE/EtOAc 4:1) R_f0.18 (UV, vanillin).

3-bromo-2-oxo-*N*-tosylcyclopentanecarboxamide (42). In a 100-mL flask equipped with a dropping funnel under argon atmosphere, β -ketoamide **31a** (1.41 g, 5.00 mmol, 1 equiv), was dissolved in glacial AcOH (15 mL) at room temperature. A solution of Br₂ (283 μ L, 5.50 mmol, 1.1 equiv) in glacial AcOH (10 mL) was placed in the dropping funnel and added dropwise. After 2 h of stirring at room temperature, acetone (1 mL) was added to quench the excess of Br₂. After an additional hour at room temperature, the reaction mixture was diluted with water (50 mL) and extracted with EtOAc (3 x 50 mL). Combined organic layers were washed with saturated Na₂S₂O₃ aqueous solution (50 mL), water (50 mL) and brine (30 mL), dried over Na₂SO₄, filtered and concentrated under vacuum. The pale yellow solid was suspended in Et₂O (10 mL), filtered, washed with Et₂O (10 mL) and dried under vacuum to afford product **42** as a white solid (1.35 g, 3.75 mmol, 75% yield).

TLC (Tol/EtOAc/ACOH 80:20:1) *R*_f 0.36 (UV, vanillin).

HRMS (ESI) calc'd for [C₁₃H₁₄BrNO₄S+H]⁺: 359.9900, found: 359.9901.

¹H NMR (400 MHz, d⁶-DMSO): δ (ppm) 12.37 (br s, 1H, 1 diastereomer), 10.76 (br s, 1 diastereomer), 7.86 (d, *J* = 8.4 Hz, 2H, 1 diastereomer), 7.47 - 7.39 (m, 2H, 2 diastereomers), 5.08 - 5.02 (m, 1H, 1 diastereomer), 4.75 - 4.63 (m, 1H, 1 diastereomer), 3.45 (d, *J* = 8.5 Hz, 1H, 1 diastereomer), 3.34 (d, *J* = 8.5 Hz, 1H, 1 diastereomer), 2.48 - 1.94 (m, 4H, 2 diastereomers), 2.39 (s, 3H, 2 diastereomers).

Because of solubility and stability issues, conjugated with the presence of diastereomers and ketone-enol tautomerism, no clear **¹³C NMR** description could be obtained.

m.p. = 143-145 °C.

(1R,3aS,6S,12aS)-1-bromo-13-tosyl-1,2,3,4,5,6-hexahydro-6,3a-(epiminomethano)benzo[4,5]oxazolo[3,2-*a*]cyclopenta[*b*]pyridin-14-one (45). Prepared according to the general procedure C using 3-bromo-2-oxo-*N*-tosylcyclopentanecarboxamide (**42**) (72.0 mg, 0.200 mmol, 1 equiv), acrolein (**32**) (27 µL, 0.400 mmol, 2 equiv) and 2-aminophenol (**12a**) (32.7 mg, 0.3 mmol, 1.5 equiv) with a reaction time of 72 h. Purification by flash chromatography over silica gel (pure CH₂Cl₂ then CH₂Cl₂/EtOAc 98:2) afforded product **45** as a yellowish solid (49.2 mg, 0.101 mmol, 50% yield, >20:1 *dr*, 39% *ee*).

TLC (CH₂Cl₂/EtOAc 95:5) R_f0.93 (UV, *p*-anisaldehyde).

- (13) We have also recently described early results of organocatalytic multicomponent reactions with α-substituted enals, however with low enantioselectivities: Du, H.; Rodriguez, J.; Bugaut, X.; Constantieux, T. *Synthesis* **2015**, *47*, 2188-2198. These results will not be further discussed in this Feature Article.
- (14) There is also a possibility to prepare in a stepwise fashion suitably substituted 4-aryl-1,4-dihydropyridines with a free nitrogen atom and to oxidize them into axially chiral 4-arylpipridine with a central-to-axial conversion of chirality: Quinonero, O.; Jean, M.; Vanthuyne, N.; Roussel, C.; Bonne, D.; Constantieux, T.; Bressy, C.; Bugaut, X.; Rodriguez, J. *Angew. Chem. Int. Ed.* **2016**, *55*, 1401-1405.
