HAL is a multi-disciplinary open access archive for the deposit and dissemination of scientific research documents, whether they are published or not. The documents may come from teaching and research institutions in France or abroad, or from public or private research centers.

L’archive ouverte pluridisciplinaire HAL, est destinée au dépôt et à la diffusion de documents scientifiques de niveau recherche, publiés ou non, émanant des établissements d’enseignement et de recherche français ou étrangers, des laboratoires publics ou privés.
Climate Negotiation Analysis

1. Introduction

Text analysis methods based on word co-occurrence have yielded useful results in humanities and social sciences research. For instance, Venturini et al., (2012) describe the use of concept co-occurrence networks in social sciences. Grimmer and Stewart (2013) survey clustering and topic modeling applied to political science corpora. Whereas these methods provide a useful overview of a corpus, they cannot determine the predicates relating co-occurring elements with each other. For instance, if France and the phrase binding commitments co-occur within a sentence, how are both elements related? Is France in favour of, or against binding commitments?

Different natural language processing (NLP) technologies can identify related elements in text, and the predicates relating them. A recent approach is open relation extraction (Mausam et al., 2012, among others), where relations are derived from the corpus in a data-driven manner, without having to pre-specify a vocabulary of predicates or actors. We are developing a workflow to analyze the Earth Negotiations Bulletin (vol. 12), which summarizes international climate negotiations. A sentence in this corpus can contain several verbal or nominal predicates indicating support and opposition (see Table 1). Results were uneven when applying open relation extraction tools to this corpus. To address these challenges, we developed a workflow with a domain model, and analysis rules that exploit annotations for semantic roles and pronominal anaphora, provided by an NLP pipeline.

Our system identifies points supported and opposed by negotiating actors and extracts keyphrases and DBpedia concepts from those points. The results are displayed on an interface, allowing for a comparison of different actors' positions. The system helps address a current need in digital humanities: tools for the quantitative analysis of textual structures beyond word co-occurrence.

The abstract is structured as follows. First, related work and the corpus are presented. Then, our system is described. Finally, evaluation is discussed.

Material supplementing the paper and access information to the system will be available on the project's website.
1. Multiple verbal predicates

The EU, with NEW ZEALAND and opposed by CHINA, MALAYSIA and BHUTAN, supported including the promotion of natural regeneration within the definitions of "afforestation" and "reforestation."

<table>
<thead>
<tr>
<th>Propositions</th>
<th>Predicate Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Actor</td>
<td>Predicate</td>
</tr>
<tr>
<td>European_Union</td>
<td>supported</td>
</tr>
<tr>
<td>New_Zealand</td>
<td>supported</td>
</tr>
<tr>
<td>Malaysia</td>
<td>~supported</td>
</tr>
<tr>
<td>Bhutan</td>
<td></td>
</tr>
</tbody>
</table>

2. Nominal predicate

Much of the discussion was on a proposal by the G-77/China to include research and development in the transport and energy sectors in the priority areas to be financed by the SCCF.

<table>
<thead>
<tr>
<th>Propositions</th>
<th>Predicate Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Actor</td>
<td>Predicate</td>
</tr>
<tr>
<td>Group_of_77/China</td>
<td>proposal</td>
</tr>
</tbody>
</table>

Table: Typical corpus sentences. Sentence 1 has predicates supported and opposed, with several actors each. Example 2 shows a nominal predicate (proposal). For Sentence 1, five <actor, predicate, negotiation point> propositions are extracted by the system, and the opposing actors (China, Malaysia, Bhutan) are assigned a proposition which is a negated version (with ~supported as the predicate) of the proposition for the main verb supported.

2. Related work

Venturini et al., (2014) created concept co-occurrence networks for the ENB corpus, using Cortex Manager, a corpus cartography tool. This analysis does not cover which predicates relate concepts and actors. Salway et al., (2014) used grammar induction on ENB to identify recurrent actor/predicate patterns; it could be tested whether results with that approach complement ours.

Some studies have used syntactic and semantic parsing for text-analysis of social sciences and humanities corpora. Diesner (2012, 2014) examines the contribution of NLP to the construction of text-based networks. Van Atteveldt (2015) used dependency parsing to apply co-occurrence based methods within sentence elements related to an actor or a predicate. These studies rely mostly on syntactic dependencies and verbal predicates. We are using semantic role labeling as the basis for relation extraction, and treating nominal predicates besides verbal ones. We also developed an interface to navigate the results.

Finally, a relevant resource for text-mining on climate corpora is climatetagger API, which links concepts against a domain-specific thesaurus (Bauer et al., 2011). This thesaurus could complement our concept-linking results (based on DBpedia, a general ontology).

3. Corpus

Each ENB issue is a 2000 word summary for one day of negotiations. The issues are written by domain experts, who strive for an objective tone and, to avoid biases, use similar expressions when reporting about all participants’ interventions (Venturini et al., 2014). The COP meetings are covered in 255 ENB issues, with ca. 35,000 sentences. The original corpus format is HTML, which we preprocessed into clean text. We dated each issue based on ENB’s table of contents.

4. System description
The system helps analyze patterns of support and opposition between negotiating parties, and the issues about which parties agree or disagree. To achieve this, the system extracts propositions of shape «actor, predicate, negotiation point». Based on a domain model containing actors and predicates, and applying analysis rules on the outputs of an NLP toolkit. Keyphrases and DBpedia concepts are also extracted from the negotiation points. All extractions, and the corpus itself, are made navigable on a user interface (UI).

### 4.1. NLP toolkit

We used the IXA Pipes library (Agerri et al., 2014), with default models for **tokenization** and **part-of-speech tagging**. We resolved some types of **pronominal anaphora** based on CorefGraph coreference chains.

**Semantic Role Labeling (SRL)** (Surdeanu et al., 2008) identifies a predicate’s arguments and their semantic functions or roles (e.g. agent). SRL was performed with ixa-pipe-srl, which tags against the PropBank database (Palmer et al., 2005) for verbal predicates and against NomBank (Meyers et al., 2004) for nominal ones.

**Keyphrase Extraction**: YaTeA (Aubin and Hamon, 2006). This library performs unsupervised term extraction using syntactic and statistical criteria.

**Entity Linking (EL)**: The tool from (Ruiz and Poibeau, 2015) was used. It combines outputs from several public EL services, selecting the best outputs with a weighted vote.

### 4.2. Domain-specific components

The **domain model** contains actors (negotiating countries and groups) and verbal or nominal predicates. Verbal predicates (from PropBank) can be neutral reporting verbs (e.g. stated), or verbs related to support and opposition (recommended, criticized). The nominal predicates (from NomBank) express similar notions to the verbs (e.g. proposal, objection). The model also specifies a predicate type: report, support, or oppose.

**Analysis rules** were implemented to identify propositions based on the semantic roles of predicates’ arguments, previously obtained with SRL. Most domain predicates involve an agent and a message expressed by the agent (who agrees with the message, objects to it, or just reports it). Thus, actor mentions in a predicate’s A0 argument represent the actor who expresses the message, and the predicate’s A1 argument often represents the negotiation point addressed by the actor. The generic rule to identify propositions is in Figure 1.

#### Rule: Generic proposition

for each predicate \( p \):
- resolve negation (see below)
- for each pronoun he, she, it in \( p \)'s A0 argument:
  - apply anaphora resolution (see below)
- for each actor-mention am in \( p \)'s A0 argument:
  - create a proposition «am, \( p \), point», where point is a concatenation of \( p \)'s A1 arguments

---

**Figure**: General rule to create a proposition

Sentences with opposed by constructions require a different analysis (e.g. China, opposed by the EU, recommended…) In such sentences, a different rule creates, for the opposing actors, propositions where the predicate contradicts the main clause’s predicate (see Table 1 for an example). Proposition-creation rules for more specific cases have also been implemented.

The treatment of negation relies on finding AM-NEG roles (see footnote 12) attached to a predicate, or negative items (not, lack) in a window of two tokens preceding a predicate.
Pronominal anaphora was treated via custom rules operating on the output of a coreference resolver (see footnote 9). We created custom rules since, in the corpus, he and she (besides it) can refer back to a country (pronoun gender depends on the country’s delegate).

To facilitate searches by date-range, propositions are assigned their documents’ date.

4.3. User interface

The UI (Figure 2) helps analyze actors’ negotiation positions. It allows searching for documents matching a text query (Text search box), and for propositions matching a given actor (Actors box) or a given predicate (Actions box). Propositions matching a query are displayed on the left panel, documents for a query on the right. Aggregated keyphrases and DBpedia concepts for the content matching a query (documents or propositions) are displayed in tabs on the right panel. The AgreeDisagree view provides an overview of keyphrases and concepts from propositions where selected actors agree or disagree. Simultaneous access on the UI to the corpus and the annotations helps researchers validate results.

The implementation framework is Django, with Solr search. We’re working on allowing the user export results and edit the model’s actors and predicates.
5. Evaluation

It is important to assess whether the system can help domain-experts gain insights they would not have otherwise obtained, e.g. detect previously unnoticed generalizations (see e.g. Berry, 2012). This type of evaluation is ongoing; we are collaborating with political scientists, whose initial feedback on the tool has been positive. User validation of the interface is also ongoing.

The system’s NLP components were evaluated in literature cited above. Results are state-of-the-art or competitive, and available on our project’s website (sites.google.com/site/nlp4climate).

To evaluate the model and analysis rules that create domain-relevant propositions, we have manually annotated a set of corpus sentences with propositions. Details about the test-set, evaluation metrics and results are on the website. We consider the results satisfactory.

6. Outlook

A useful feature would be an annotation confidence score, that users could employ to establish priorities in manual result revision. A useful application of the propositions extracted would be creating network graphs with different types of edges representing support and opposition among parties, and between parties and issues.

6.1. Acknowledgements

We thank Tommaso Venturini, Audrey Baneyx, Kari de Pryck and Diégo Antolinos-Basso from the Sciences Po médialab in Paris for domain-expert feedback on the system. Pablo Ruiz is supported by a PhD grant from Région Ile-de-France.
