Dinuclear Iridium and Rhodium Complexes with Bridging Arylimidazolide- N^3,C^2 Ligands: Synthetic, Structural, Reactivity, Electrochemical and Spectroscopic Studies[†]

Fan He,^a Laurent Ruhlmann,^b Jean-Paul Gisselbrecht,^b Sylvie Choua,^c Maylis Orio,^e Marcel Wesolek,^a Andreas A. Danopoulos,^{*a,d} Pierre Braunstein^{*a}

Deprotonation of 1-arylimidazoles (aryl = mesityl (Mes), 2,6-diisopropylphenyl (Dipp)), with *n*-butyl lithium afforded the corresponding derivatives (1-aryl-1*H*-imidazol-2-yl)lithium (**1a**, Ar = Mes; **1b**, Ar = Dipp) in good yield. Reaction of **1a** with 0.5 equiv. of [Ir(cod){μ-Cl}]₂ yielded two geometrical isomers of a doubly C2,N3-bridged dinuclear complex [Ir(cod){μ-C₃H₂N₂(Mes)-κC2,κN3}]₂ (**3**), **3_{H-H}**, a head-to-head (H-H) isomer of C_s symmetry, and **3_{H-T}**, the thermodynamically preferred head-to-tail (H-T) isomer of C₂ symmetry. The metalated carbon of the 4 electron donor anionic bridging ligands has some carbene character, reminiscent of the situation in N-metalated protic NHC complexes. Displacement of cod ligands from **3_{H-H}** and **3_{H-T}** afforded the tetracarbonyl complexes [Ir(CO)₂{μ-C₃H₂N₂(Mes)-κC2,κN3}]₂ **4_{H-H}** and **4_{H-T}**, respectively. The reaction with PMe₃, which gave only one complex, [Ir(CO)(PMe₃){μ-C₃H₂N₂(Mes)-κC2,κN3}]₂ (**5**), demonstrates that the isomerization of the central core Ir[μ-C₃H₂N₂(Mes)-κC2,κN3]Ir from H-H to H-T on going from **4_{H-H}** to **5** is readily triggered by phosphine substitution under mild conditions. Oxidative-addition of MeI to **5** afforded the formally metal-metal bonded d⁷-d⁷ complex [Ir₂(CO)₂(PMe₃)₂(Me)I{μ-C₃H₂N₂(Mes)-κC2,κN3}]₂ (**6**). The blue [Ir(C₂H₄)₂{μ-C₃H₂N₂(Mes)-κC2,κN3}]₂ (**7**) and purple [Rh(C₂H₄)₂{μ-C₃H₂N₂(Dipp)-κC2,κN3}]₂ (**9**) tetraethylene complexes were also obtained with only a H-T arrangement of the bridging ligands. Although only modestly efficient in alkane dehydrogenation, complex **7** was found to be a more active pre-catalyst than **3_{H-T}**, **4_{H-T}** and **5**, probably because of the favorable lability of the ethylene ligands. From cyclic voltammetry, exhaustive coulometry and spectroelectrochemistry studies, it was concluded that **3_{H-T}** undergoes a metal-based one electron oxidation to generate the mixed-valent Ir(I)/Ir(II) system. The energy of the intervalence band for the orange dirhodium complex [Rh(cod){μ-C₃H₂N₂(Mes)-κC2,κN3}]₂ (**8**) is shifted toward lower energies in comparison with **3_{H-T}**, reflecting the decrease of the energy with the intermetallic distance. It was concluded from the EPR study that the Ir and Rh centres contribute substantially to the experimental magnetic anisotropy and thus to the singly occupied molecular orbital (SOMO) in the mixed-valent Ir(I)/Ir(II) and Rh(I)/Rh(II) systems. The molecular structures of **3_{H-H}**, **3_{H-T}**, **8** and **9** were

determined by X-ray diffraction.

Introduction

The isolation by Arduengo and co-workers of stable N-heterocyclic carbenes (NHCs) of the imidazole type with bulky *N*-substituents,¹ has triggered a fast growing interest for this class of ligands, in particular in organometallic chemistry.² Protic NHCs (pNHCs) are characterised by the presence of a N-bound H atom and have been comparatively much less investigated, despite their strong σ -donor character and the possibility for the NH group to be involved in secondary interactions of potential relevance to bifunctional catalysis,³ substrate recognition⁴ and biological systems.⁵

Different synthetic methodologies allow access to pNHC metal complexes: building the C-bound heterocycle in the metal coordination sphere,⁶ using suitable N-protecting groups that are removed after metal coordination,⁷ or facilitating the kinetic formation of the M–C_{NHC} bond by the oxidative-addition of the C–X bond of halo-imidazoles (X = halide).⁸ Most recently, we found that *N*-arylimine-functionalized pNHC Ir(I) and Ir(III) complexes could be readily obtained from cationic or neutral Ir(I) imidazole complexes using excess TlPF₆ or [Ir(cod)(μ-Cl)]₂, respectively.⁹ Deprotonation of such a pNHC Ir(I) complex was shown to give rise to an equilibrium between a mononuclear complex containing a C-bound ‘anionic’ imidazolide and its dimer in which this moiety binds in a μ-C,N bridging mode (Scheme 1).⁹

Scheme 1 Deprotonation of a protic NHC (pNHC) Ir(I) complex leading to an equilibrium between a mononuclear complex containing a C-bound ‘anionic’ imidazolide and its dimer.⁹

Anionic imidazolides possess interesting properties. Lithium 1-methyl-(4-*t*-butyl)imidazolide was found by Boche and co-workers to have carbene character, as supported by the ¹³C NMR chemical shift of its C2 atom (δ 195.9) and an X-ray diffraction study.¹⁰ Kostyuk and co-workers reported a method to synthesize N-phosphorylated carbenes by the reaction between lithium imidazolides, bearing a bulky N-bound *t*-butyl or adamantyl group, and di(*t*-butyl)chlorophosphine.¹¹ Furthermore, an imidazolide can act as a N,C-bidentate ligand, comparable to a pyrazolide. While dinuclear bis(μ-pyrazolido)iridium(I) complexes have been widely investigated in oxidative addition reactions,¹² substitution chemistry,¹³ kinetic¹⁴ and theoretical studies,¹⁵ no extensive study on dinuclear iridium complexes bearing imidazolides has yet been carried out.¹⁶ A brief report described in 1983 the synthesis of

dinuclear imidazolide Rh(I) complexes by deprotonation with MeLi of a mononuclear imidazole complex.¹⁷ As part of our current investigations on the tautomerism/metallotropism between pNHC and imidazole ligands in iridium complexes (Scheme 2),⁹ we describe herein the synthesis, structural and spectroscopic characterisation, reactivity and electrochemical properties of a series of doubly C,N-bridged dinuclear iridium and rhodium complexes bearing 1-arylimidazolide ligands.

Scheme 2 Tautomerism/metallotropism between pNHC and imidazole ligands.⁹

Results and discussion

Synthesis and characterisation of the di-iridium complexes.

Starting from 1-arylimidazoles (aryl = mesityl (Mes), 2,6-diisopropylphenyl (Dipp)), the corresponding derivatives (1-aryl-1*H*-imidazol-2-yl)lithium (1a, Ar = Mes; 1b, Ar = Dipp) were prepared in good yield by deprotonation with a stoichiometric amount of *n*-butyl lithium in pentane at -30 °C (Scheme 3).

Scheme 3 Synthesis of (1-aryl-1*H*-imidazol-2-yl)lithium (1a,b).

In their NMR spectra in THF-*d*₈, the absence of the ¹H NMR resonance of the proton at C2 and the values of ¹³C{¹H} NMR resonance due to the C2 carbon, at δ 205.8 for (1-mesityl-1*H*-imidazol-2-yl)lithium (1a) and δ 202.3 for (1-(2,6-diisopropylphenyl)-1*H*-imidazol-2-yl)lithium (1b), consistent with the metallation of this carbon.

Scheme 4 Stepwise or direct synthesis of the two isomers of the dinuclear complexes **3_{H-H}** and **3_{H-T}**.

Treatment of **1a** with 0.5 equiv. of $[\text{Ir}(\text{cod})(\mu\text{-Cl})_2]$ at -78°C in THF led to the formation of the doubly C,N-bridged dinuclear complex $[\text{Ir}(\text{cod})\{\mu\text{-C}_3\text{H}_2\text{N}_2(\text{Mes})\text{-}\kappa\text{C}2,\kappa\text{N}3\}]_2$ (**3**) as a red solid in nearly quantitative yield (Scheme 4). Its ^1H and $^{13}\text{C}\{^1\text{H}\}$ NMR spectra in C_6D_6 revealed the presence of a *ca.* 40:60 mixture of two constitutional isomers, **3_{H-H}**, a head-to-head isomer of C_s symmetry, and **3_{H-T}**, a head-to-tail isomer of C_2 symmetry. In the NMR spectra of the mixture in C_6D_6 , each isomer displays one set of mesityl, imidazolide and cod signals. The chemical shifts of the $^{13}\text{C}\{^1\text{H}\}$ NMR resonance due to the C2 carbon (δ 171.3 and 172.0) are considerably upfield-shifted when compared to the value of 205.8 ppm in **1a**. It turned out to be difficult to efficiently separate and isolate each isomer pure out of this mixture because of their similar solubility properties. Another procedure to prepare doubly C,N-bridged dinuclear complexes was found to consist of the deprotonation of 1-mesitylimidazolyl(cycloocta-1,5-diene)iridium(I) chloride $[\text{Ir}(\text{cod})\text{Cl}\{\text{C}_3\text{H}_3\text{N}_2(\text{Mes})\text{-}\kappa\text{N}3\}]$ (**2**) with a stoichiometric amount of potassium bis(trimethylsilyl)amide (KHMDs) in THF at -78°C . According to the NMR spectra, a *ca.* 40:60 mixture of the same two isomers **3_{H-H}** and **3_{H-T}** was again obtained. However, when the reaction using **1a** was repeated in Et_2O ,^{16b} the resulting red suspension was found to consist of a *ca.* 90:10 mixture of **3_{H-H}** and **3_{H-T}**, **after dissolution in toluene and ^1H NMR analysis**. This difference in proportions obtained in THF is likely due to the lower solubility of **3_{H-H}** in Et_2O . After recrystallization from a toluene/ Et_2O solution at -30°C , deep red crystals of one pure isomer were obtained in 80% yield. In its ^1H NMR spectrum (C_6D_6), the C4 and C5 imidazolyl protons positions gave rise to an AX pattern at δ 7.20 (d) and 6.42 (d, $^3J = 1.4$ Hz). In the $^{13}\text{C}\{^1\text{H}\}$ NMR spectrum, the three resonances at δ 171.3, 125.5 and 122.4 are assigned to the C2, C4 and C5 imidazolyl carbons, respectively. However, a definitive assignment of this isomer as H-H or H-T arrangement was impossible on the exclusive basis of the spectroscopic data. Fortunately, its structure was elucidated by X-ray diffraction analysis and established its H-H arrangement. The molecular structure of **3_{H-H}** is shown in Fig. 1, with selected bond lengths and angles. The C_s molecular symmetry of the complex in solution is almost retained in the solid state, as indicated by NMR spectroscopy. The boat conformation of **3_{H-H}** is similar to that of the analogous bridged pyrazolido complex.^{12b} There is no direct iridium-iridium interaction, the separation between the metal atoms being 3.1844(9) Å. The iridium(I) centres adopt an approximate square planar coordination geometry, defined by two olefinic bonds of the 1,5-cyclooctadiene ligand and two carbon atoms (or two nitrogen atoms) from the imidazolide bridging ligands. The latter can be formally considered as 4 electron anionic donors toward Ir(I) centres. The electronic arrangement at the metals is unsymmetrical and Ir(1) is more electron-rich than Ir(2) since it is bound to two carbanionic donors. The C1–N1 [1.35(2) Å] and C21–N3 [1.35(2) Å] (3σ) bond lengths are not significantly shorter than those of C1–N2 [1.38(2) Å] and C21–

N4 [1.39(2) Å]. This is indicative of electronic delocalization between the N1, C1 and N2 atoms (N3, C21 and N4, respectively) and of a carbene character for C1 and C21, respectively (Scheme 5).

Scheme 5 Limiting resonance structures for the diiridium(I) complex **3_{H-H}** emphasising the dipolar nature of this isomer.

Fig. 1 Molecular structure of **3_{H-H}**. H atoms and methyl groups are omitted for clarity. Thermal ellipsoids are at the 30% level. Selected bond lengths (Å) and angles ($^\circ$): Ir1...Ir2 3.1844(9), C1–N1 1.35(2), C1–N2 1.38(2), Ir1–C1 2.05(1), Ir1–C21 2.05(1), Ir1–C13 2.14(1), Ir1–C14 2.18(1), Ir1–C17 2.17(2), Ir1–C18 2.16(2), C13–C14 1.38(2), C17–C18 1.36(3), C21–N3 1.35(2), C21–N4 1.39(2), Ir2–N1 2.07(1), Ir2–N3 2.06(1), Ir2–C33 2.10(1), Ir2–C34 2.09(1), Ir2–C37 2.11(2), Ir2–C38 2.10(2), C33–C34 1.39(3), C37–C38 1.40(3), N1–C1–N2 106(1), N3–C21–N4 105(1), C1–Ir1–C21 87.4(6), C13–Ir1–C14 37.2(6), C14–Ir1–C17 80.6(7), C17–Ir1–C18 36.5(7), C18–Ir1–C13 81.4(6), N1–Ir2–N3 86.5(5), C33–Ir2–C34 38.7(7), C34–Ir2–C37 82.8(6), C37–Ir2–C38 38.7(7), C38–Ir2–C33 81.3(7).

The whole complex **3_{H-H}** can be thermally converted to its isomer **3_{H-T}** upon refluxing a THF solution for 24 h (Scheme 4). In the ^1H NMR spectrum of **3_{H-T}** in C_6D_6 , the protons at the imidazolide backbone carbons C4 and C5 give rise to an AX pattern at δ 7.02 (d) and 6.09 (d, $^3J = 1.6$ Hz). In the $^{13}\text{C}\{^1\text{H}\}$ NMR spectrum, the resonances at δ 125.4 and 121.3 are assigned to C4 and C5, respectively. The $^{13}\text{C}\{^1\text{H}\}$ NMR resonance of the imidazolide C2 carbon (C1 and C21 in Fig. 2) in **3_{H-T}** (δ 172.0) is downfield shifted compared to that in **3_{H-H}** (δ 171.3) (C1 and C21 in Fig. 1). Single crystals of **3_{H-T}** suitable

for X-ray diffraction were obtained by slow diffusion of a layer of Et₂O into a THF solution of **3**_{H-T} at room temperature under argon. The molecular structure of **3**_{H-T} is shown in Fig. 2, with selected bond lengths and angles.

Fig. 2 Molecular structure of **3**_{H-T}. H atoms and methyl groups are omitted for clarity. Thermal ellipsoids are at the 30% level. Selected bond lengths (Å) and angles (°): Ir1...Ir2 3.1407(2), C1–N1 1.349(5), C1–N2 1.373(5), Ir1–C1 2.058(4), Ir1–N4 2.068(3), Ir1–C13 2.121(4), Ir1–C14 2.112(4), Ir1–C17 2.166(4), Ir1–C18 2.158(4), C13–C14 1.409(6), C17–C18 1.390(6), C21–N3 1.378(5), C21–N4 1.335(5), Ir2–N1 2.067(3), Ir2–C21 2.043(4), Ir2–C33 2.135(4), Ir2–C34 2.118(4), Ir2–C37 2.168(4), Ir2–C38 2.159(4), C33–C34 1.404(7), C37–C38 1.395(6); N1–C1–N2 106.1(3), N3–C21–N4 106.7(3), C1–Ir1–N4 86.9(1), C13–Ir1–C14 38.9(2), C14–Ir1–C17 82.0(2), C17–Ir1–C18 37.5(2), C18–Ir1–C13 81.2(2), N1–Ir2–C21 86.6(1), C33–Ir2–C34 38.6(2), C34–Ir2–C37 82.0(2), C37–Ir2–C38 37.6(2), C38–Ir2–C33 81.2(2).

A boat conformation is observed for the structure of **3**_{H-T}, similar to that of its isomer **3**_{H-H}. The distance between two iridium atoms (3.1407(2) Å) is shorter than in **3**_{H-H} but still too long to represent a direct metal-metal interaction. Each iridium atom has a 16 valence electron configuration and adopts an approximate square planar coordination geometry, defined by two olefinic bonds of the 1,5-cyclooctadiene ligand, one carbon atom of one imidazolidine and one nitrogen atom of the other bridging imidazolidine ligand. The C1–N1 distance of

1.349(5) Å is only slightly shorter than C1–N2 1.373(5), likewise for C21–N4 1.335(5) compared to C21–N3 1.378(5), which would be consistent with a more pronounced double bond character for the N–C bond in the bridging part of the ligands (Scheme 6).

Scheme 6 Limiting resonance structures for **3**_{H-T}, with a dominant contribution of the imidazolidine form (right) to the actual structure.

Displacement Reactions of the cod Ligands.

With the original aim to prepare derivatives of **3**_{H-H} and **3**_{H-T} in which replacement of the cod ligands with two-electron donor ligands could modify the redox properties, as monitored by cyclic voltammetry, the tetracarbonyl derivatives [Ir(CO)₂{μ-C₃H₂N₂(Mes)-κC2,κN3}]₂ (**4**_{H-H} and **4**_{H-T}, respectively) were readily synthesized by reaction with carbon monoxide in Et₂O (Scheme 7). While a clear brown Et₂O solution of **4**_{H-T} was obtained, the reaction with **3**_{H-H} led to a yellow suspension. The higher solubility of **4**_{H-T} in Et₂O compared to that of **4**_{H-H} is consistent with their different polarity. Indeed, **4**_{H-T} has a good solubility in nonpolar solvents such as pentane or *n*-hexane. The ¹³C{¹H} NMR spectroscopic data for **4**_{H-H} and **4**_{H-T} in C₆D₆ show for each isomer one set of mesitylimidazolidine and two CO signals, consistent with either a C_s or C₂ molecular symmetry. Compared to the cod precursors (**3**_{H-H} and **3**_{H-T}), the ¹³C{¹H} NMR resonances of the imidazolidine C2 are downfield shifted (δ 172.8 in **4**_{H-H} and δ 175.1 in **4**_{H-T}). The IR spectra of **4**_{H-H} and **4**_{H-T} show three ν(CO) bands at 2060, 2037, 1954 and 2059, 2041, 1968 cm⁻¹, respectively, corresponding to the pattern for a dinuclear, folded tetracarbonyl framework.

Scheme 7 Reactions of **3_{H-H}** and **3_{H-T}** with CO or PMe₃.

The reaction of **4_{H-H}** or **4_{H-T}** with 2.0 equiv. of trimethylphosphine in toluene at room temperature afforded the same red solid [Ir(CO)(PMe₃)₂]₂{μ-C₃H₂N₂(Mes)-κC2,κN3}₂ (**5**), which shows two ν(CO) bands at 2000 and 1911 cm⁻¹ in the infra-red spectrum (Scheme 7). According to the NMR spectra in C₆D₆, this complex contains one set of mesitylimidazolidine, trimethylphosphine and CO signals. The imidazolidine backbone protons at C4 and C5 are observed at δ 6.89 (d) and 6.68 (d, ³J = 0.9 Hz) and the corresponding ¹³C{¹H} NMR resonances at δ 128.3 and 120.1. In the ¹³C{¹H} NMR spectrum, the resonances due to the CO and C_{imidazolidine} carbons are found at δ 181.4 (d, J_{C-P} = 10.0 Hz) and 177.1 (d, J_{C-P} = 112.0 Hz), respectively. The coordinated trimethylphosphine ligands give rise to a ¹H NMR resonance at δ 1.13 (d, ²J_{H-P} = 8.7 Hz), a ¹³C{¹H} NMR signal at δ 17.0 (d, J_{C-P} = 31.6 Hz) and a singlet in ³¹P{¹H} NMR at δ 24.1. All these data are consistent with a C₂ molecular symmetry for **5**, i.e. a H-T arrangement. The isomerization of the central core Ir[μ-C₃H₂N₂(Mes)-κC2,κN3]₂Ir from H-H to H-T on going from **4_{H-H}** to **5** has thus been triggered by phosphine substitution under mild conditions. The preference for the H-T arrangement is consistent with **3_{H-T}** being the thermodynamically favored isomer of **3**.

Oxidative-Addition of MeI.

Treatment of **5** with a slight excess of MeI afforded a yellow product [Ir₂(CO)₂(PMe₃)₂(Me)I]₂{μ-C₃H₂N₂(Mes)-κC2,κN3}₂ (**6**) corresponding to a 1:1 addition product (Scheme 7). The observation in C₆D₆ of two sets of ¹H NMR signals for the mesitylimidazolidine and trimethylphosphine protons and of ¹³C{¹H} NMR signals for the CO ligands is consistent with a non-symmetric system. In the ¹³C{¹H} NMR spectrum, the resonances of the C_{imidazolidine} carbons are significantly upfield shifted (δ 142.8 and 140.8 vs. δ 177.1 in **5**). The ³¹P{¹H} NMR spectrum shows two close resonances at δ -46.6 and -48.9, consistent with similarly bonded but inequivalent phosphine ligands.^{12a} Attempts to crystallize **6** were unsuccessful. The IR spectrum of **6** shows two ν(CO) bands at 2019 and 1952 cm⁻¹,

indicative of a smaller back-bonding from the metal to the CO ligands compared to **5** and consistent with the presence of iridium(II) centres in the formally metal-metal bonded **6**.

Synthesis and Characterisation of Diiridium Tetraethylene Complexes

Treatment of **1a** with 0.5 equiv. [Ir(C₂H₄)₂(μ-Cl)]₂ at -78 °C in Et₂O led to the formation of the doubly C,N-bridged imidazolidine dinuclear complex [Ir(C₂H₄)₂]₂{μ-C₃H₂N₂(Mes)-κC2,κN3}₂ (**7**) as a blue solid in 77% yield (Scheme 8).

Scheme 8 Synthesis of the isolated dinuclear olefinic complexes **7-9**.

The colour of **7** is similar to that of other tetraethylene diiridium complexes reported in the literature.^{13c} Its NMR spectra in C₆D₆ only showed one set of mesitylimidazolidine signals. In the ¹³C{¹H} NMR spectrum, the resonance of the

Cimidazole is observed at δ 171.5. The imidazolid protons at C4 and C5 gave rise to an AX pattern at δ 7.09 (d) and 6.49 (d, $^3J = 1.5$ Hz) and the corresponding $^{13}\text{C}\{^1\text{H}\}$ NMR resonances occurred at δ 124.6 and 122.0, respectively. In the ^1H NMR spectrum, two AA'BB' patterns are anticipated for the chemically-distinct coordinated ethylene ligands (trans to C and trans to N).^{13c,18} The resolution of the spectra did not allow to extract all the corresponding coupling constants. Nevertheless, one AA'BB' pattern with δ_{B} 3.13 and δ_{A} 2.89 and a second AA'BB' pattern with δ_{B} 2.63 and δ_{A} 2.36 were observed.¹⁹ Since the ^1H NMR chemical shifts of the mesityl and imidazolid groups are similar to those of **3**_{H-T}, the arrangement of **7** should also be H-T but attempts to crystallize **7** were unsuccessful.

Synthesis and Characterisation of Dirhodium cod and Tetraethylene Complexes

To extend the scope of the reactivity of **1a**, it was treated with 0.5 equiv. of $[\text{Rh}(\text{cod})(\mu\text{-Cl})_2]$, and the new complex $[\text{Rh}(\text{cod})\{\mu\text{-C}_3\text{H}_2\text{N}_2(\text{Mes})\text{-}\kappa\text{C}2,\kappa\text{N}3\}]_2$ (**8**) was isolated (Scheme 8). As for **8**, the $^{13}\text{C}\{^1\text{H}\}$ NMR spectrum of **8** in C_6D_6 only showed one set of mesitylimidazolyl signals and a doublet due to C2 at δ 176.2 ($J_{\text{C-Rh}} = 50.4$ Hz). The protons at C4 and C5 were observed in the ^1H NMR spectrum at δ 6.96 and 6.51 as two broad singlets (the $^3J_{\text{H-H}}$ coupling was not resolved) and the corresponding $^{13}\text{C}\{^1\text{H}\}$ resonances were found at δ 126.8 and 120.3. Orange single crystals of **8** suitable for X-ray diffraction were grown from a toluene solution at 0 °C under argon. The molecular structure of **8** is shown in Fig. 3, with selected bond lengths and angles. This complex adopts a H-T arrangement and the same boat conformation like its iridium analog. The separation between the two Rh atoms is 3.2117(4) Å, which is too long to represent a direct metal-metal interaction. Each rhodium atom is in a 16 valence electron configuration and adopts an approximate square planar geometry, defined by two olefinic bonds of the 1,5-cyclooctadiene ligand, one carbon atom of one imidazolid and one nitrogen atom of the another bridging imidazolid ligand.

Fig 3 Molecular structure of **8**. H atoms and methyl groups are omitted for clarity. Thermal ellipsoids are at the 30% level. Selected bond lengths (Å) and angles (°): Rh1...Rh2 3.2117(4), C1-N1 1.376(3), C1-N2 1.342(3), Rh1-C1 2.045(2), Rh1-N4 2.079(2), Rh1-C25 2.135(3), Rh1-C26 2.117(3), Rh1-C29 2.188(3), Rh1-C30 2.171(3), C25-C26 1.382(4), C29-C30 1.372(4), C13-N3 1.378(3), C13-N4 1.345(3), Rh2-N2 2.067(3), Rh2-C13 2.043(4), Rh2-C33 2.172(3), Rh2-C34 2.183(3), Rh2-C37 2.118(3), Rh2-C38 2.122(3), C33-C34 1.376(4), C37-C38 1.392(4); N1-C1-N2 106.7(2), N3-C13-N4 106.3(2), C1-Rh1-N4 85.73(9), C25-Rh1-C26 37.9(1), C26-Rh1-C29 82.3(1), C29-Rh1-C30 36.7(1), C30-Rh1-C25 81.4(1), N2-Rh2-C13 86.27(9), C33-Rh2-C34 36.8(1), C34-Rh2-C37 82.1(1), C37-Rh2-C38 38.3(1), C38-Rh2-C33 81.5(1).

The reaction of **1b** with $[\text{Rh}(\text{C}_2\text{H}_4)_2(\mu\text{-Cl})_2]$ at -78 °C in Et_2O afforded $[\text{Rh}(\text{C}_2\text{H}_4)_2\{\mu\text{-C}_3\text{H}_2\text{N}_2(\text{Dipp})\text{-}\kappa\text{C}2,\kappa\text{N}3\}]_2$ (**9**) (Scheme 8). Its NMR spectrum in C_6D_6 only showed one set of Dipp imidazolid signals and a doublet due to C2 at δ 175.1 ($J_{\text{C-Rh}} = 49.0$ Hz). The resonances of the H atoms at the backbone carbons C4 and C5 were observed at δ 7.02 and 6.64, respectively, as two singlets, and the corresponding $^{13}\text{C}\{^1\text{H}\}$ NMR resonances at δ 125.9 and 122.8. In the ^1H NMR spectrum, like in **7**, two AA'BB' patterns are anticipated for the chemically-distinct coordinated ethylene ligands.^{13c,18} However, the resolution of the spectra did not allow extraction of all the corresponding coupling constants. Nevertheless one AA'BB' pattern with δ_{B} 3.65 and δ_{A} 3.58 and a second AA'BB' pattern with δ_{B} 2.86 and δ_{A} 2.62 were observed.¹⁹ Purple single crystals of **9** suitable for X-ray diffraction were grown from *n*-hexane solution at -30 °C under ethylene atmosphere. A similar reaction using **1a** instead of **1b** proceeded similarly (^1H monitoring) although a well-characterised solid product could not be obtained due to limited solubility in hexane from which **9** could be crystallised. The molecular structure of **9** is shown in Fig. 4, with selected bond lengths and angles. The structure of **9** adopts a boat conformation and like in **8**, the arrangement of the bridging ligands is of the H-T type. The separation between two Rh atoms is 3.3146(9) Å, which is again too long to represent a direct bonding interaction. Each 16 electron rhodium atom adopts an approximately square planar geometry, defined by two ethylene ligands, one carbon atom

of one imidazolide and one nitrogen atom of the other bridging imidazolide ligand. Like in **3_{H-T}**, the metrical data indicate a more pronounced double bond character for the N-C bond located in the bridging part of the ligands.

Fig. 4 Molecular structure of **9**. H atoms and isopropyl groups are omitted for clarity. Thermal ellipsoids are at the 30% level. Selected bond lengths (Å) and angles (°): Rh1...Rh2 3.3146(9), C1-N1 1.372(3), C1-N2 1.344(3), Rh1-C1 2.040(3), Rh1-N4 2.081(2), Rh1-C16 2.141(3), Rh1-C17 2.125(3), Rh1-C18 2.208(3), Rh1-C19 2.192(3), C16-C17 1.369(5), C18-C19 1.351(5), C20-N3 1.379(3), C20-N4 1.342(3), Rh2-N2 2.080(2), Rh2-C20 2.041(3), Rh2-C35 2.202(3), Rh2-C36 2.211(3), Rh2-C37 2.129(3), Rh2-C38 2.124(3), C35-C36 1.354(5), C37-C38 1.385(5); N1-C1-N2 106.7(2), N3-C20-N4 106.4(2), C1-Rh1-N4 84.6(1), C16-Rh1-C17 37.4(1), C17-Rh1-C19 89.2(2), C18-Rh1-C19 35.8(1), C16-Rh1-C18 86.9(1), N2-Rh2-C20 84.9(1), C35-Rh2-C36 35.7(1), C36-Rh2-C38 87.0(1), C37-Rh2-C38 38.0(1), C35-Rh2-C37 89.1(2).

Electrochemical investigations.

We have shown above that the oxidative-addition of MeI to the diiridium H-T complex **5** occurred at the dinuclear unit to give formally an Ir(II)-Ir(II) complex rather than involving one metal centre to give a mixed-valence Ir(I)/Ir(III) complex. We thus became interested in studying of the redox behavior of representatives of these dinuclear complexes, in particular, with respect to the two possible H-T or H-H arrangements of the bridging ligands, which lead to a symmetrical or unsymmetrical electronic environment of the metal centres, respectively. An electrochemical investigation of complexes **3_{H-T}** and **8** was carried out by cyclic voltammetry and rotating disk voltammetry in CH₂Cl₂ + 0.1 M [*n*-Bu₄N]PF₆. Cyclic voltammograms of the **3_{H-T}** and **8** with added ferrocene are presented in Figures S1 and S2 (see ESI) and show reversible processes. In contrast, irreversible oxidation was observed by cyclic voltammetry in the case of complex **3_{H-H}** (see Figure Sxxx in ESI)

As shown in Fig. 5 and Table 1, two successive oxidations have been detected in the case of **3_{H-T}**. The first oxidation step occurs at -0.45 V vs. Fc⁺/Fc and corresponds to a reversible

electron transfer, while the second step presents an irreversible oxidation peak at +0.67 V vs. Fc⁺/Fc.

The number of electrons exchanged during the first oxidation step was determined by exhaustive coulometry. During the electrolysis, the oxidation current decreased exponentially with time. When this current reached the residual value measured in the absence of electroactive material, typically after 4 h under the above conditions, the number of electrons transferred was 0.9/molecule of **3_{H-T}**, which strongly suggests that oxidation of only one Ir(I) centre to Ir(II) has occurred, leading to the mixed-valent Ir(I)/Ir(II) intermediate. Attempts to chemically oxidize **3_{H-T}** using AgOTf in CH₂Cl₂ gave intractable mixture of species.

Table 1. Electrochemical data for **3_{H-T}** and **8**.^a

Complex	$E_{1/2}$ V non visible dans le pdf	Fc ^{+/0} non visible dans le pdf
3_{H-T}	-0.45 (64)	+0.67 ^b
8	-0.40 (63)	+0.58 ^b

^a All potentials in V vs. Fc⁺/Fc were obtained from cyclic voltammetry in CH₂Cl₂ containing 0.1 mol/L [*n*-Bu₄N]PF₆. Scan rate = 0.1 V s⁻¹. Working electrode: glassy carbon electrode. The given half-wave potentials in the case of the reversible couple are equal to $E_{1/2} = (E_{pa} - E_{pc})/2$. In bracket: (ΔE_p , peak splitting in mV at a scan rate of 0.1 Vs⁻¹). ^b Irreversible electron transfer.

Fig. 5 Cyclic voltammograms of the **3_{H-T}** (CH₂Cl₂ + 0.1 M [*n*-Bu₄N]PF₆, glassy carbon electrode, scan rate 0.1 Vs⁻¹, vs. Fc⁺/Fc).

In-situ spectroelectrochemical studies have been carried out, under argon atmosphere, to gain further insight into the nature of the electrogenerated species during this first reversible oxidation (Fig. 6).

Fig. 6 A) Time-resolved UV-visible-NIR spectra of **3_{H-T}** for the first oxidation step (transition Ir(I)/Ir(I) to Ir(I)/Ir(II)) in $\text{CH}_2\text{Cl}_2 + 0.1 \text{ M } [n\text{-Bu}_4\text{N}]\text{PF}_6$ (spectra recorded every 5 s). B) UV-visible spectral evolution for the first oxidation step.

For **3_{H-T}**, time resolved UV-Vis-NIR spectroelectrochemistry data were recorded during cyclic voltammetry between -0.70 V and $+0.20 \text{ V}$ vs. Fc^+/Fc (scan rate 20 mVs^{-1}). As seen from the array of spectra depicted in Fig. 6, during the oxidation the generated Ir(I)/Ir(II) species is characterised by low-energy intervalence charge transfer (IVCT) bands in the near infrared region at 1024 nm . On the reverse potential scan, a decrease of the intensity for this IVCT band was observed and the oxidized Ir(I)/Ir(II) system reverted quantitatively to the initial Ir(I)/Ir(I) species.

From the results obtained by cyclic voltammetry (reversible oxidation at -0.45 V vs. Fc^+/Fc), exhaustive coulometry (one-electron process) and spectroelectrochemistry (new NIR band at $\lambda_{\text{max}} = 1024 \text{ nm}$ for the oxidized system), it can be concluded that **3_{H-T}** undergoes a one electron oxidation on the metal generating the mixed-valent Ir(I)/Ir(II) system, in equilibrium with Ir(II)/Ir(I), and giving rise to an IVCT band in the NIR region.

For comparison, we examined a H-T dirhodium complex. Features similar to those for **3_{H-T}** were observed with **8** and the mixed-valent system Rh(I)/Rh(II). The cyclic voltammogram

shows two successive oxidations, the first at -0.40 V vs. Fc^+/Fc corresponds to a reversible electron transfer, while the second step is associated to an irreversible oxidation process at $+0.58 \text{ V}$ vs. Fc^+/Fc (Fig. 7). Again, exhaustive coulometry indicated a number of electrons transferred of $0.9/\text{molecule}$ for **8**, leading to the mixed-valent intermediate Rh(I)/Rh(II).

Fig. 7 Cyclic voltammograms of the **8** ($\text{CH}_2\text{Cl}_2 + 0.1 \text{ M } [n\text{-Bu}_4\text{N}]\text{PF}_6$, Glassy carbon electrode, scan rate 0.1 Vs^{-1} , vs. Fc^+/Fc).

Spectroelectrochemistry measurements at the first oxidation process evidenced a new high-energy intervalence charge transfer (IVCT) band around 1073 nm , which is in good agreement with the formation of a mixed-valent intermediate Rh(I)/Rh(II) (Fig. 8). The new band at 612 nm might correspond to the Rh(II).

For **8** and for **3_{H-T}**, we observed one additional band at 612 nm and 781 nm , respectively. In studies on mixed-valent Ir(I)/Ir(II) or Rh(I)/Rh(II) intermediates, similar bands were also observed, but not at the same wavelength, because of the presence of different ligands.²⁰ Such bands may be attributed to the Ir(II) or Rh(II) component of the complexes.

Fig. 8 A) Time-resolved UV-visible-NIR spectra of **8** for the first oxidation step (transition Rh(I)/Rh(I) to Rh(I)/Rh(II)) in $\text{CH}_2\text{Cl}_2 + 0.1 \text{ M } [n\text{-Bu}_4\text{N}]\text{PF}_6$ (spectra recorded every 5 s). B) Time-resolved UV-visible-NIR differential spectra for the first oxidation step.

For a dinuclear system, the electronic coupling calculated from the Hush equation²¹ decreases with the distance between the metal centers. Hush proposed that the electronic coupling could be extracted from the intervalence band shape according to eq (1):

$$H_{ab} = 0.0206(\epsilon_{\max}\Delta\nu_{1/2}\lambda)^{1/2}/d_{ab} \quad (1)$$

where $\epsilon_{\max}$ ($\text{M}^{-1}\cdot\text{cm}^{-1}$) is the maximum intensity, $\Delta\nu_{1/2}$ (cm^{-1}) is the width at half-height, λ (cm^{-1}) is the energy maximum band (E_{op}), and d_{ab} ($\text{\AA}$) is the diabatic electron-transfer distance. E_{op} occurs at 9823 cm^{-1} ($\lambda_{\text{max}} = 1018 \text{ nm}$) and at 9320 cm^{-1} ($\lambda_{\text{max}} = 1073 \text{ nm}$) for **3_{H-T}** and **8**, respectively. Correspondingly, $\Delta\nu_{1/2}$ are 47393 cm^{-1} and 40486 cm^{-1} . According to eq (1), the corresponding calculated electronic couplings are $H_{\text{Ir-Ir}} = 3960 \text{ cm}^{-1}$ and $H_{\text{Rh-Rh}} = 4746 \text{ cm}^{-1}$. Thus, the energy of the intervalence band for **8** is shifted toward lower energies in comparison with **3_{H-T}**, reflecting the decrease of the energy with the intermetallic distance ($d_{\text{Ir-Ir}} = 3.141 \text{ \AA}$, $d_{\text{Rh-Rh}} = 3.212 \text{ \AA}$).

The transition from charge localized to charge-delocalized (which are also called class II and class III, respectively, in the Robin–Day terminology)²² occurs at $\lambda = 2H_{ab}$, so mixed-valent (MV) compounds with $\lambda > 2H_{ab}$ are charge-localized and those with $\lambda < 2H_{ab}$ are charge-delocalized. In our case:

$$\mathbf{3}_{\text{H-T}}: \lambda (9823 \text{ cm}^{-1}) > 2H_{ab} (2 \times 3960 = 7920 \text{ cm}^{-1})$$

$$\mathbf{8}: \lambda (9320 \text{ cm}^{-1}) < 2H_{ab} (2 \times 4746 = 9492 \text{ cm}^{-1})$$

For **8**, $\lambda (9320 \text{ cm}^{-1})$ is $\sim 2H_{ab}$

These data thus suggest that **3_{H-T}** is a charge-localized while **8** is a charge-delocalized system under the conditions of our room temperature measurements.

EPR measurements.

EPR spectroscopy constitutes a highly suitable tool to evaluate the electronic structure of metal complexes with unpaired electrons, especially on heavy metal centres. At low temperature, the average $\langle g \rangle$ value and the anisotropy (Δg) calculated from the principal values of the g -tensor afford a qualitative estimate of the extent of electron localization over the metal and/or over the ligand.²³ We thus wanted to examine in more detail the electronic structure of the mixed-valent Ir(I)/Ir(II) and Rh(I)/Rh(II) species. The oxidized species were generated at room temperature by electrolysis after consumption of about 0.9 electron/molecule and the resulting solutions were transferred into an EPR tube under argon. The X-band EPR spectrum in frozen CH_2Cl_2 solution of Ir(I)/Ir(II) (the oxidized species of **3_{H-T}**) exhibited a signal with an axial symmetry (Fig. 9) with $g_1 = g_2 = 1.987$ and $g_3 = 2.123$ values (see Table 2). Increasing the temperature to ambient caused the EPR signal to disappear. In the case of the Rh(I)/Rh(II) system obtained by oxidation of **8**, the EPR spectrum at low temperature displayed a rhombic signal (Fig. S7 in ESI). At room temperature, a very weak EPR signal is recorded with only one line centered at around $g = 2.00$ without hyperfine structure. Satisfying simulations were obtained with one or two equivalent ^{103}Rh nucleus ($I = 1/2$ isotopic abundance 100%) and in order to discriminate between the two possibilities DFT calculations were performed. The structure of the Rh(I)/Rh(II) complex was subjected to geometry optimization (Fig. S8) and its electronic structure was investigated (Fig. S9). Mulliken population analysis indicates an equally distributed spin density between the two rhodium atoms with positive spin populations found at Rh(1) (0.49) and Rh(2) (0.49). The spin density of the Rh atoms accounts for 90% of the total spin density and the remaining 10% are spread over the ligands. The Singly Occupied Molecular Orbital (SOMO) of the complex displays 90% Rh character and features the σ antibonding interaction between the Rh $3d_{z^2}$ orbitals. The EPR parameters arising from the spectral simulation for two equivalent ^{103}Rh nuclei are reported in Table 2.

Table 2. EPR parameters of the oxidized complexes

	g_1	g_2	g_3	$\langle g \rangle^a$	Δg^b	$\frac{A_{\text{Ir}}}{A_{\text{Rh}}}$	$\frac{A_{\text{Rh}}}{A_{\text{Ir}}}$	$\frac{A_{\text{Ir}}}{A_{\text{Rh}}}$
Ir(I)/Ir(II)	1.987	1.987	2.123	2.033	0.136	-	-	-
Rh(I)/Rh(II)	1.993	2.031	2.105	2.043	0.112	33	18	27

^a $\langle g \rangle = [(g_1^2 + g_2^2 + g_3^2)/3]^{1/2}$; ^b $\Delta g = g_3 - g_1$

Fig. 9 EPR spectra of the Ir(I)/Ir(II) system electrochemically generated from **3_{H-T}** system electrochemically generated in CH₂Cl₂ at 100 K: a) Experimental spectrum b) Simulated spectrum.

The oxidized forms are characterised by a g anisotropy and the average g values are significantly larger than for the free electron (2.0023). Such features may imply that the Ir and Rh centres contribute substantially to the experimental magnetic anisotropy and thus to SOMO.

Attempted catalytic transfer dehydrogenation of cyclooctane using iridium complexes **3_{H-T}**, **4_{H-T}**, **5** and **7** as precatalysts.

Iridium pincer complexes have shown very promising catalytic properties in alkane dehydrogenation reactions,²⁴ due to their high thermal stability and high efficiency. The synergistic action of two reactive sites in close proximity could be seen as a key element in the design of powerful catalysts. This prompted us to explore the catalytic activity of these dinuclear iridium complexes towards alkane dehydrogenation. The reaction of cyclooctane (COA) and *t*-butylethylene (TBE), as sacrificial olefin, to form cyclooctene (COE) and *t*-butylethane (TBA) catalyzed by the POCOP iridium pincer complex²⁵ was employed in the benchmark reaction.

Table 3. Catalytic transfer dehydrogenation of cyclooctane in the presence of *t*-butylethylene with **3_{H-T}**, **4_{H-T}**, **5** and **7**^a

entry	catalyst	TON ^b	TOF ^c /h ⁻¹
1	3_{H-T}	4.6	0.46
2	4_{H-T}	-	-
3	5	5.8	0.58
4	7	62.4	6.24

^a Reaction conditions: [Ir₂] catalyst (0.010 mmol), COA (4.0 mL, 30.3 mmol), TBE (0.40 mL, 3.1 mmol), 200 °C, 10 h; ^b the number of moles of COA that a mole of [Ir₂] catalyst can convert in 10 h; ^c turnover number per hour.

The results of preliminary experiments on the catalytic transfer dehydrogenation of COA to COE are summarized in Table 3. Using complex **7** as precursor gave better results and 2.06% of the cyclooctane was converted to *cis*-cyclooctene at a TOF of 6.24 h⁻¹. This higher value compared to the other pre-catalysts is probably due to the easier de-coordination of the ethylene ligands from the iridium centres, which facilitates the metal-alkane interactions.

Conclusions

In this work, we have provided a more detailed investigation on dinuclear Ir(I) and Rh(I) complexes containing a bridging 1-arylimidazolid ligand, C2 and N3-bound to the metals.^{16b} Initial deprotonation of 1-arylimidazoles (aryl = mesityl (Mes), 2,6-diisopropylphenyl (Dipp)) by *n*-butyl lithium in pentane at -30 °C was carried out to afford the corresponding derivatives (1-aryl-

1*H*-imidazol-2-yl)lithium (**1a,b**) which were then used to prepare the doubly C,N-bridged dinuclear Ir(I) complexes **3**. These Ir(I) complexes exist in two isomeric forms, **3_{H-H}** which is the head-to-head isomer of *C_s* symmetry, and **3_{H-T}**, the head-to-tail isomer of *C₂* symmetry, which is thermodynamically more stable. The X-ray diffraction data suggest electron delocalisation within the N...C...N system and thus some carbene character for the Ir-bound imidazolidine carbon atom, that is more pronounced in **3_{H-H}**. The metal-bound imidazolidine may be viewed as a deprotonated pNHC system. When the tetracarbonyl derivatives **4_{H-H}** and **4_{H-T}** were reacted with PMe₃, one CO ligand was displaced from each Ir centre and only one isomer was formed, **5**, in which the imidazolidine ligands are bound in a H-T manner. This ligand arrangement was retained in the formally metal-metal bonded, d⁷-d⁷ Ir(II)-Ir(II) complex, **6**, resulting from oxidative-addition of MeI across **5**. From the results obtained by cyclic voltammetry, exhaustive coulometry and spectroelectrochemistry, it was concluded that **3_{H-T}** undergoes a metal-based one electron oxidation to generate the mixed-valent Ir(I)/Ir(II) system, in equilibrium with Ir(II)/Ir(I), characterised by an IVCT band in the NIR region.

EPR studies combined with DFT calculations suggested that the Ir and Rh centres contribute substantially to the experimental magnetic anisotropy in the oxidized species and thus to the SOMO. These data evidenced that both Ir(II)/Ir(I) and Rh(II)/Rh(I) complexes are delocalized mixed-valent species.

The dinuclear iridium complexes were found to be only moderately active pre-catalysts in the reaction of cyclooctane and *t*-butylethylene to form cyclooctene and *t*-butylethane. Whether these results are directly linked to a difficulty to access coordinatively unsaturated and reactive species or to an inhibiting effect of the cod ligands cannot be stated at this stage. In favour of the latter hypothesis is that slightly better performances were obtained with the tetraethylene complex **7**, may be due to the favourable lability of the ethylene ligands.

Experimental

General Considerations

All manipulations involving organometallics were performed under argon in a Braun glove-box or using standard Schlenk techniques. Solvents were dried using standard methods and distilled over sodium/ benzophenone under argon prior use or passed through columns of activated alumina and subsequently purged with argon. The starting materials [Rh(cod)(μ-Cl)]₂,²⁶ [Ir(C₂H₄)₂(μ-Cl)]₂^{12h} and [Rh(C₂H₄)₂(μ-Cl)]₂²⁷ were prepared according to the literature and [Ir(cod)(μ-Cl)]₂ is commercially available from Johnson Matthey PLC. NMR spectra of complexes were recorded on a Bruker 300 MHz, 400 MHz, 500 MHz or 600 MHz instrument at ambient temperature and referenced using the proton (¹H) or carbon (¹³C) resonance of the residual solvent, with downfield shifts reported as positive. Assignments are based on ¹H, ¹H-COSY, ¹H-NOESY, ¹H/¹³C-HSQC, and ¹H/¹³C-HMBC experiments. ³¹P{¹H} NMR spectra were recorded on a Bruker Avance 300 instrument at 121.49 MHz using H₃PO₄ (85% in D₂O) as external standard. IR spectra were recorded in the region 4000–100 cm⁻¹ on a Nicolet 6700 FT-IR spectrometer (ATR mode, diamond crystal). Elemental analyses were performed by the "Service de microanalyses", Université de Strasbourg.

Synthetic procedures

(1-Mesityl-1*H*-imidazol-2-yl)lithium (1a). To a stirred solution of 1-mesitylimidazole (1.49 g, 8.0 mmol) in pentane (30 mL) was added dropwise a solution of *n*-BuLi (1.6 M in *n*-hexane, 5.0 mL, 8.0 mmol) at -78 °C over 2 min. The reaction mixture was stirred for 1 h at -30 °C, then allowed to warm to room temperature and stirred for another 2 h. The resulting clear orange solution was evaporated in vacuo. The residue was washed with pentane (3 × 5 mL) to yield a white powder which was collected by filtration and dried in vacuo (1.08 g, 70%). ¹H NMR (500 MHz, THF-d₈): δ 7.04 (s, 1H, NCHCHN_(mesityl)), 6.83 (s, 2H, aryl-*H*), 6.70 (s, 1H, NCHCHN_(mesityl)), 2.25 (s, 3H, *p*-CH₃(_{mesityl})), 1.95 (s, 6H, *o*-CH₃(_{mesityl})). ¹³C{¹H} NMR (125 MHz, THF-d₈): δ 205.8 (NCN_(mesityl)), 142.3 (C_(mesityl)), 136.5 (C_(mesityl)), 135.5 (C_(mesityl)), 128.3 (CH_(mesityl)), 127.9 (NCHCHN_(mesityl)), 116.8 (NCHCHN_(mesityl)), 20.9 (*p*-CH₃(_{mesityl})), 18.2 (*o*-CH₃(_{mesityl})).

(1-(2,6-Diisopropylphenyl)-1*H*-imidazol-2-yl)lithium (1b). To a stirred solution of 1-(2,6-diisopropylphenyl)-imidazole (1.83 g, 8.0 mmol) in pentane (30 mL) was added dropwise a solution of *n*-BuLi (1.6 M in *n*-hexane, 5.0 mL, 8.0 mmol) at -78 °C over 2 min. Then the reaction mixture was allowed to warm to room temperature and stirred for another 2 h. The precipitate was collected by filtration, washed with pentane and dried in vacuo to obtain a white powder (1.72 g, 92%). ¹H NMR (500 MHz, THF-d₈): δ 7.19 (t, ³J = 7.6 Hz, 1H, *p*-aryl-*H*), 7.11 (d, ³J = 7.6 Hz, 2H, *m*-aryl-*H*), 7.04 (s, 1H, NCHCHN_(Dipp)), 6.81 (s, 1H, NCHCHN_(Dipp)), 2.72 (sept, ³J = 6.9 Hz, 2H, CH(CH₃)₂), 1.04 (d, ³J = 6.9 Hz, 6H, CH(CH₃)₂), 1.03 (d, ³J = 6.9 Hz, 6H, CH(CH₃)₂). ¹³C{¹H} NMR (125 MHz, THF-d₈): δ 202.3 (NCN_(Dipp)), 147.4 (C_(Dipp)), 142.2 (C_(Dipp)), 127.4 (NCHCHN_(Dipp)), 127.1 (CH_(Dipp)), 123.0 (CH_(Dipp)), 119.0 (NCHCHN_(Dipp)), 28.3 (CH(CH₃)₂), 25.1 (CH(CH₃)₂), 24.3 (CH(CH₃)₂).

1-Mesitylimidazolyl(cycloocta-1,5-diene)iridium(I) chloride [Ir(cod)Cl{C₃H₃N₂(Mes)-κN3}] (2). A solution of 1-mesitylimidazole (0.028 g, 0.15 mmol) in THF (2 mL) was added to a stirred solution of [Ir(cod)(μ-Cl)]₂ (0.050 g, 0.074 mmol) in THF (2 mL). The mixture was stirred for 1 h at room temperature and then the volatiles were removed in vacuo. The residue was washed with pentane (3 × 2 mL) and dried under vacuum to give a yellow powder (0.074 g, 0.14 mmol, 94%). ¹H NMR (500 MHz, CD₂Cl₂): δ 8.27 (apparent t, ⁴J = 1.4 Hz, 1H, NCHN), 7.28 (apparent t, ^{3,4}J = 1.4 Hz, 1H, NCHCHN_(mesityl)), 6.99 (s, 2H, aryl-*H*), 6.96 (apparent t, ^{3,4}J = 1.4 Hz, 1H, NCHCHN_(mesityl)), 4.20 (br s, 2H, CH_(cod)), 3.71 (br s, 2H, CH_(cod)), 2.33 (s, 3H, *p*-CH₃(_{mesityl})), 2.27 (m, 4H,

[Rh(C₂H₄)₂{μ-C₃H₂N₂(Dipp)-κC2,κN3}]₂ (9). To a stirred solution of **1b** (0.120 g, 0.51 mmol) in Et₂O (10 mL) was added a solution of [Rh(C₂H₄)₂(μ-Cl)]₂ (0.085 g, 0.25 mmol) in Et₂O (5 mL) at -78 °C. The reaction mixture was allowed to warm to room temperature gradually and was further stirred for 4 h. After removal of the volatiles under vacuum, the residue was extracted with *n*-hexane and the solution was filtered through Celite. The filtrate was concentrated to ca. 4 mL under reduced pressure and then was cooled to -30 °C in an ethylene atmosphere to obtain purple crystals, which were stored at -30 °C (0.135 g, 70%). ¹H NMR (400 MHz, C₆D₆): δ 7.28 (d, ³J = 4.4 Hz, 4H, *m*-aryl-H), 7.08 (t, ³J = 4.4 Hz, 2H, *p*-aryl-H), 7.02 (s, 2H, NCHCHN_(Dipp)), 6.64 (s, 2H, NCHCHN_(Dipp)), 3.65 (B part of a broad poorly resolved AA'BB' spin system, 4H, CH₂(ethylene)) and 3.58 (A part of a broad poorly resolved AA'BB' spin system, 4H, CH₂(ethylene)), 3.25 (sept, ³J = 6.8 Hz, 2H, CH(CH₃)₂), 2.86 (B part of an AA'BB' spin system with |N| ≈ 7.5 Hz and poorly resolved Rhodium coupling, 4H, CH₂(ethylene)) and 2.62 (A part of an AA'BB' spin system with |N| ≈ 7.5 Hz and poorly resolved Rhodium coupling, 4H, CH₂(ethylene)), 2.48 (sept, ³J = 6.8 Hz, 2H, CH(CH₃)₂), 1.73 (d, ³J = 6.8 Hz, 6H, CH(CH₃)₂), 1.16 (d, ³J = 6.8 Hz, 6H, CH(CH₃)₂), 1.06 (d, ³J = 6.8 Hz, 6H, CH(CH₃)₂), 0.80 (d, ³J = 6.8 Hz, 6H, CH(CH₃)₂). ¹³C{¹H} NMR (100 MHz, C₆D₆): δ 175.1 (d, ¹J_{C-Rh} = 49.0 Hz, NCN_(Dipp)), 147.1 (C_(Dipp)), 146.1 (C_(Dipp)), 137.8 (C_(Dipp)), 128.9 (CH_(Dipp)), 125.9 (NCHCHN_(Dipp)), 124.1 (CH_(Dipp)), 123.8 (CH_(Dipp)), 122.8 (NCHCHN_(Dipp)), 78.7 (d, ¹J_{C-Rh} = 6.6 Hz, CH₂(ethylene)), 58.0 (d, ¹J_{C-Rh} = 12.1 Hz, CH₂(ethylene)), 28.8 (CH(CH₃)₂), 28.3 (CH(CH₃)₂), 26.3, 24.9, 24.2 and 23.4 (CH(CH₃)₂). Calcd for C₃₈H₅₄Rh₂N₄ (%): C, 59.07; H, 7.04; N, 7.25. Found: C, 58.63; H, 6.87; N, 7.42.

Catalytic transfer dehydrogenation of cyclooctane.

In a preliminary investigation, a red suspension of complex **3_{H-T}** (9.7 mg, 0.010 mmol) in a mixture of COA (4.0 mL, 30.3 mmol) and TBE (0.40 mL, 3.1 mmol), in a sealed tube under argon, was heated at 200 °C for 10 h (Table 3, entry 1). Gas chromatographic (GC) analysis of the products indicated 0.15% of the cyclooctane was converted to *cis*-cyclooctene at a turnover

frequency (TOF) 0.46 h^{-1} . The formation of TBA, confirmed by GC and ^1H NMR analysis, also indicated that the transfer dehydrogenation reaction did occur. When complex **4_{H-T}** was used as the precatalyst under the same reaction conditions (Table 3, entry 2), no catalytic activity was observed. In the catalytic reaction using complex **5** (Table 3, entry 3), in which two CO ligands of complex **4** are replaced by two molecules of PMe_3 , GC analysis of the products indicated that 0.19% of the cyclooctane was converted to *cis*-cyclooctene at a TOF of 0.58 h^{-1} . Better results were obtained with complex **7** where 2.06% of the cyclooctane was converted to *cis*-cyclooctene at a TOF of 6.24 h^{-1} .

X-ray Data Collection, Structure Solution, and Refinement for All Compounds.

Suitable crystals for the X-ray analysis of all compounds were obtained as described above. Data for **3_{H-H}**, **3_{H-T}** and **8** were collected on an APEX-II CCD (graphite-monochromated Mo-K α radiation, $\lambda = 0.71073\text{ \AA}$) at 173(2) K and data for **9** were collected on a Kappa CCD diffractometer (graphite-monochromated Mo-K α radiation, $\lambda = 0.71073\text{ \AA}$) at 173(2) K. Crystallographic and experimental details for these structures are summarized in Table S1. The structures were solved by direct methods (SHELXS-97²⁸) and refined by full-matrix least-squares procedures (based on F^2 , SHELXL-97) with anisotropic thermal parameters for all the non-hydrogen atoms. The hydrogen atoms were introduced into the geometrically calculated positions (SHELXS-97 procedures). The SQUEEZE instruction in PLATON was applied for **9** and the residual electron density was assigned to half a molecule of disordered *n*-hexane. In **9**, one methyl group (C11) was found disordered over two positions.

Electrochemistry

All compounds were studied in $\text{CH}_2\text{Cl}_2 + 0.1\text{ mM } [n\text{-Bu}_4\text{N}]\text{PF}_6$. $[n\text{-Bu}_4\text{N}]\text{PF}_6$ (Fluka, electrochemical grade) and CH_2Cl_2 (Merck, UVasol[®]) were used as received. The electrochemical measurements were carried out at room temperature ($20\text{ }^\circ\text{C}$) in CH_2Cl_2 containing $0.1\text{ M } [n\text{-Bu}_4\text{N}]\text{PF}_6$ in a classical three-electrode cell. The electrolyte was degassed by bubbling argon through the solution for at least 5 min, and an argon flow was kept over the solution during measurements. The electrochemical cell was connected to a computerized multipurpose electrochemical device (Autolab, Eco Chemie BV, The Netherlands) controlled by a GPES software (v. 4.7) running on a PC computer. The working electrode was a glassy carbon (GC) disk electrode (diameter: 3 mm), used either motionless for cyclic voltammetry (100 mV s^{-1} to 10 V s^{-1}) or as a rotating disk electrode. The auxiliary electrode was a Pt wire, and the pseudo reference electrode a Pt wire. All potentials are given vs. Fc^+/Fc used as internal reference in agreement with the IUPAC recommendation²⁹ and are uncorrected from ohmic drop.

The number of exchanged electrons for the first oxidation step was determined by exhaustive electrolysis. Prior to electrolysis, the corresponding mixtures were stirred and degassed by bubbling argon through the solution for 10 min. Then, the desired working potential was applied. During anodic oxidation, the electrolyzed solution was continuously stirred and maintained under argon. Coulometric measurements were performed in a standard 40 mL cell. The working and the auxiliary electrodes were a platinum wire (o.d. 0.8 mm) of 15 cm length. For the controlled-potential electrolysis, the anodic and cathodic compartments were separated by a fritted glass disk to prevent diffusion of the electrogenerated species.

The reference electrode was a saturated calomel electrode (SCE) that was electrically connected to the studied solution by a junction bridge filled with the corresponding solvent-supporting electrolyte solution.

Spectroelectrochemical experiments were carried out as described elsewhere,³⁰ using a Zeiss MCS 601 UV–vis–NIR diode array spectrometer.

UV-visible-NIR spectroscopy

UV–Vis absorption spectra have been recorded for $4.41 \times 10^{-5}\text{ mol L}^{-1}$ (**3_{H-T}**) and $8.07 \times 10^{-5}\text{ mol L}^{-1}$ (**8**) solutions in CH_2Cl_2 on a Perkin–Elmer Lambda 35 spectrophotometer in quartz cells (1 cm). The UV-visible-NIR absorption spectroscopic measurements were performed in CH_2Cl_2 . The optical absorption spectrum of **3_{H-T}** (Figure S3) was characterised by a band in the visible domain around 525 nm ($\epsilon_{525\text{ nm}} = 3648\text{ dm}^3\text{ mol}^{-1}\text{ cm}^{-1}$). In the case of the **8** (Figure S4), the band was observed at 476 nm ($\epsilon_{476\text{ nm}} = 4585\text{ dm}^3\text{ mol}^{-1}\text{ cm}^{-1}$).

EPR experiments

EPR spectra were recorded with an EMX spectrometer (Bruker) operating at X-band and equipped with a standard HSN cavity and a variable temperature attachment. Computer simulations of the EPR spectra were performed with the help of Easy Spin software.³¹

DFT calculations

All theoretical calculations were performed with the ORCA program package.³² Geometry optimization was carried out using the GGA functional BP86³³ and by taking advantage of the resolution of the identity (RI) approximation in the Split-RI-J³⁴ variant with the appropriate Coulomb fitting sets.³⁵ Increased integration grids (Grid4 and GridX4 in ORCA convention) and tight SCF convergence criteria were used. Solvent effects were accounted for according to the experimental conditions. For that purpose, we used the CH_2Cl_2 ($\epsilon = 9.08$) solvent within the framework of the conductor like screening (COSMO) dielectric continuum approach.³⁶ Electronic structures were

obtained from single-point calculations using the B3LYP³⁷ functional. Scalar relativistic effects were included using the scalar relativistic zero-order regular approximation (ZORA)³⁸ and the scalar relativistically recontracted (SARC)³⁹ version of the def2-TZVP(-f) basis set together with the decontracted def2-TZVP/J Coulomb fitting basis sets for all atoms. Spin density and molecular orbitals were plotted using the orca_plot utility program and visualized with Chemcraft⁴⁰ software.

Acknowledgements

The USIAS, CNRS, UdS, Région Alsace and Communauté Urbaine de Strasbourg are gratefully acknowledged for the award of fellowships and a Gutenberg Excellence Chair (2010–11) to AAD and support. We also thank the ucFRC (www.icfrc.fr) for support and the China Scholarship Council for a PhD grant to F. H., and the Service de Radiocristallographie (Institut de Chimie, Strasbourg) for the determination of the crystal structures.
