On the total variation Wasserstein gradient flow and the TV-JKO scheme

Guillaume Carlier∗ Clarice Poon †

February 28, 2017

Abstract

We study the JKO scheme for the total variation, characterize the optimizers, prove some of their qualitative properties (in particular a sort of maximum principle and the regularity of level sets). We study in detail the case of step functions. Finally, in dimension one, we establish convergence as the time step goes to zero to a solution of a fourth-order nonlinear evolution equation.

Keywords: total variation, Wasserstein gradient flows, JKO scheme, fourth-order evolution equations.

MS Classification: 35G31, 49N15.

1 Introduction

Variational schemes based on total variation are extremely popular in image processing for denoising purposes, in particular the seminal work of Rudin, Osher and Fatemi [27] has been extremely influential and is still the object of an intense stream of research, see [10] and the references therein. Continuous-time counterparts are well-known to be related to the $L^2$ gradient flow of the total variation, see Bellettini, Casselles and Novaga [4] and the mean-curvature flow, see Evans and Spruck [15]. The gradient flow of the total variation for other Hilbertian structures may be natural as well and in

†Centre for Mathematical Sciences, University of Cambridge, Wilberforce Rd, Cambridge CB3 0WA, United Kingdom, Email: C.M.H.S.Poon@maths.cam.ac.uk
particular the $H^{-1}$ case, leads to a singular fourth-order evolution equation studied by Giga and Giga [16], Giga, Kuroda and Matsuoka [17]. In the present work, we consider another metric, namely the Wasserstein one.

Given an open subset $\Omega$ of $\mathbb{R}^d$ and $\rho \in L^1(\Omega)$, recall that the total variation of $\rho$ is given by
\[
J(\rho) := \sup \left\{ \int_{\Omega} \text{div}(z) \rho : z \in C^1_c(\Omega), \|z\|_{L^\infty} \leq 1 \right\}
\] (1.1)
and $\text{BV}(\Omega)$ is by definition the subspace of $L^1(\Omega)$ consisting of those $\rho$’s in $L^1(\Omega)$ such that $J(\rho)$ is finite. The following fourth-order nonlinear evolution equation
\[
\partial_t \rho + \text{div} \left( \rho \nabla \text{div} \left( \frac{\nabla \rho}{|\nabla \rho|} \right) \right) = 0, \text{ on } (0, T) \times \Omega, \rho|_{t=0} = \rho_0,
\] (1.2)
supplemented by the zero-flux boundary condition
\[
\rho \nabla \text{div} \left( \frac{\nabla \rho}{|\nabla \rho|} \right) \cdot \nu = 0 \text{ on } \partial \Omega
\] (1.3)
has been proposed in [7] for the purpose of denoising image densities. Numerical schemes for approximating the solutions of this equation have been investigated in [7, 14, 5]. One should of course interpret the nonlinear term $\text{div} \left( \nabla \rho / |\nabla \rho| \right)$ as the negative of an element of the subdifferential of $J$ at $\rho$.

At least formally, when $\rho_0$ is a probability density on $\Omega$, (1.2)-(1.3) can be viewed as the Wasserstein gradient flow of $J$ (we refer to the textbooks of Ambrosio, Gigli, Savaré [2] and Santambrogio [28], for a detailed exposition). Following the seminal work of Jordan, Kinderlehrer and Otto [18] for the Fokker-Planck equation, it is reasonable to expect that solutions of (1.2) can be obtained, at the limit $\tau \to 0^+$, of the JKO Euler implicit scheme:
\[
\rho^0_0 = \rho_0, \quad \rho^0_{k+1} \in \arg\min \left\{ \frac{1}{2\tau} W^2_2(\rho^k_0, \rho) + J(\rho), \rho \in \text{BV}(\Omega) \cap \mathcal{P}_2(\Omega) \right\}
\] (1.4)
where $\mathcal{P}_2(\Omega)$ is the space of Borel probability measures $\Omega$ with finite second moment and $W^2_2$ is the quadratic Wasserstein distance:
\[
W^2_2(\rho_0, \rho_1) := \inf_{\gamma \in \Pi(\rho_0, \rho_1)} \left\{ \int_{\mathbb{R}^d \times \mathbb{R}^d} |x - y|^2 \text{d}\gamma(x, y) \right\},
\] (1.5)
$\Pi(\rho_0, \rho_1)$ denoting the set of transport plans between $\rho_0$ and $\rho_1$ i.e. the set of probability measures on $\mathbb{R}^d \times \mathbb{R}^d$ having $\rho_0$ and $\rho_1$ as marginals. Our aim is to study in detail the discrete TV-JKO scheme (1.4) as well as its connection.
with (suitable weak solutions) of the PDE (1.2). Although the assertion that (1.2) is the TV Wasserstein gradient flow is central to the numerical schemes described in [7, 14, 5], there has been so far, to the best of our knowledge, no theoretical justification of this fact.

Fourth-order equations which are Wasserstein gradient flows of functionals involving the gradient of $\rho$, such as the Dirichlet energy or the Fisher information, have been studied by McCann, Matthes and Savaré [24] who found a new method the flow interchange technique to prove higher-order compactness estimates, we refer to [19] for a recent reference on this topic. The total variation is however too singular for such arguments to be directly applicable, as far as we know.

The paper is organized as follows. In section 2, we start with the discussion of a few examples. Section 3 is devoted to some properties of solutions of JKO steps and in particular a maximum principle based on a result of [12]. Section 4 establishes optimality conditions for JKO steps thanks to an entropic regularization scheme. Section 5 discusses regularity properties of the boundaries of the level sets of JKO solutions. In section 6, we address in detail the case of step functions in dimension one. Finally, in section 7, we prove convergence of the JKO scheme, as $\tau \to 0^+$, in the case of a strictly positive and bounded initial condition on a bounded interval of the real line.

2 Some examples

We first recall the Kantorovich dual formulation of $W_2^2$:

$$\frac{1}{2} W_2^2(\mu_0, \mu_1) = \sup \left\{ \int_{\mathbb{R}^d} \psi d\mu_0 + \int_{\mathbb{R}^d} \varphi d\mu_1 : \psi(x) + \varphi(y) \leq \frac{|x-y|^2}{2} \right\} \quad (2.1)$$

an optimal pair $(\psi, \varphi)$ for this problem is called a pair of Kantorovich potentials. The existence of Kantorovich potentials is well-known and such potentials can be taken to be conjugates of each other, i.e. such that

$$\varphi(x) = \inf_{y \in \mathbb{R}^d} \{ \frac{1}{2} |x-y|^2 - \psi(y) \}, \quad \psi(y) = \inf_{x \in \mathbb{R}^d} \{ \frac{1}{2} |x-y|^2 - \varphi(x) \};$$

which implies that $\varphi$ and $\psi$ are semi-concave (more precisely $\frac{1}{2}|.|^2 - \varphi$ is convex). If $\mu_1$ is absolutely continuous with respect to the $d$-dimensional Lebesgue measure, $\varphi$ is differentiable $\mu_1$ a.e. and the map $T = \text{id} - \nabla \varphi$ is the gradient of a convex function pushing forward $\mu_1$ to $\mu_0$ which is in fact the optimal transport between $\mu_0$ and $\mu_1$ thanks to Brenier’s theorem [6]. In
such a case, we will simply refer to $\varphi$ as a Kantorovich potential between $\mu_1$ and $\mu_0$. We refer the reader to [30] and [28] for details.

In this section, we will consider some explicit examples which rely on the following sufficient optimality condition (details for a rigorous derivation of the Euler-Lagrange equation for JKO steps will be given in section 4) in the case of the whole space i.e. $\Omega = \mathbb{R}^d$.

**Lemma 2.1.** Let $\rho_0 \in \mathcal{P}_2(\mathbb{R}^d)$, $\tau > 0$ and $\Omega = \mathbb{R}^d$ (so $J$ is the total variation on the whole space), if $\rho_1 \in \text{BV}(\mathbb{R}^d) \cap \mathcal{P}_2(\mathbb{R}^d)$ is such that

$$\frac{\varphi}{\tau} + \text{div}(z) \geq 0, \text{ with equality } \rho_1 \text{-a.e.} \quad (2.2)$$

where $\varphi$ is a Kantorovich potential between $\rho_1$ and $\rho_0$ and $z \in C^1(\mathbb{R}^d)$, with $\|z\|_{L^\infty} \leq 1$, $\text{div}(z) \in L^d$, and

$$J(\rho_1) = \int_{\mathbb{R}^d} \text{div}(z) \rho_1. \quad (2.3)$$

Then, setting

$$\Phi_{\tau,\rho_0}(\rho) := \frac{1}{2\tau} W^2_2(\rho_0, \rho) + J(\rho), \quad \forall \rho \in \text{BV}(\mathbb{R}^d) \cap \mathcal{P}_2(\mathbb{R}^d) \quad (2.4)$$

one has

$$\Phi_{\tau,\rho_0}(\rho_1) \leq \Phi_{\tau,\rho_0}(\rho), \quad \forall \rho \in \text{BV}(\mathbb{R}^d) \cap \mathcal{P}_2(\mathbb{R}^d).$$

**Proof.** For all $\rho \in \text{BV}(\mathbb{R}^d) \cap \mathcal{P}_2(\mathbb{R}^d)$, $J(\rho) \geq \int_{\mathbb{R}^d} \text{div}(z) \rho = J(\rho_1) + \int_{\mathbb{R}^d} \text{div}(z)(\rho - \rho_1)$, and it follows from the Kantorovich duality formula that

$$\frac{1}{2\tau} W^2_2(\rho_0, \rho) \geq \frac{1}{2\tau} W^2_2(\rho_0, \rho_1) + \int_{\mathbb{R}^d} \frac{\varphi}{\tau} (\rho - \rho_1).$$

The claim then directly follows from (2.2). \qed

### 2.1 The case of a characteristic function

A simple illustration of Lemma 2.1 in dimension 1 concerns the case of a uniform $\rho_0$, (here and in the sequel we shall denote by $\chi_A$ the characteristic function of the set $A$):

$$\rho_0 = \rho_{\alpha_0}, \quad \alpha_0 > 0, \quad \rho_{\alpha} := \frac{1}{2\alpha} \chi_{[-\alpha, \alpha]}.$$ 

It is natural to make the ansatz that the minimizer of $\Phi_{\tau,\rho_0}$ defined by (2.4) remains of the form $\rho_1 = \rho_{\alpha_1}$ for some $\alpha_1 > \alpha_0$. The optimal transport
between $\rho_{\alpha_1}$ and $\rho_0$ being the linear map $T = \frac{\alpha_0}{\alpha_1} \text{id}$, a direct computation gives

$$\Phi_{\tau,\rho_0}(\rho_{\alpha_1}) = \frac{1}{\alpha_1} + \frac{1}{6\tau}(\alpha_1 - \alpha_0)^2$$

which is minimal when $\alpha_1$ is the only root in $(\alpha_0, +\infty)$ of

$$\alpha_1^2(\alpha_1 - \alpha_0) = 3\tau. \quad (2.5)$$

To check that this is the correct guess, we shall check that the conditions of Lemma 2.1 are met. First define the Kantorovich potential

$$\varphi(x) = \frac{1}{2\alpha_1}(\alpha_1 - \alpha_0)x^2 - \frac{3\tau}{2\alpha_1} \quad \text{and } \quad z_1$$

by

$$\tau z_1(x) := -\frac{(\alpha_1 - \alpha_0)}{6\alpha_1}x^3 + \frac{3\tau x}{2\alpha_1}, \quad x \in [-\alpha_1, \alpha_1]$$

extended by 1 on $[1, +\infty)$ and $-1$ on $(-\infty, -1)$. Then $-1 \leq z_1 \leq 1$ (use the fact that it is odd and nondecreasing on $[0, \alpha_1]$ thanks to (2.5)), also $z_1'(\pm \alpha_1) = 0$ so that $z_1 \in C^1([\mathbb{R}])$ and $z_1(\alpha_1) = 1, z_1(-\alpha_1) = -1$ hence $J(\rho_1) = -\int_{\mathbb{R}} z_1 D\rho_1 = \int_{\mathbb{R}} z_1' \rho_1$ (here and in the sequel $D\rho_1$ denotes the Radon measure which is the distributional derivative of the BV function $\rho_1$). Moreover $\tau z_1' + \varphi \geq 0$ with an equality on $[-\alpha_1, \alpha_1]$. The optimality of $\rho_1 = \rho_{\alpha_1}$ then directly follows from Lemma 2.1.

Of course, the argument can be iterated so as to obtain the full TV-JKO sequence:

$$\rho_{k+1} = \text{argmin } \Phi_{\tau,\rho_k} = \left(\frac{\alpha_{k+1}^\tau}{\alpha_k^\tau} \text{id}\right) \# \rho_k = \left(\frac{\alpha_k^\tau}{\alpha_0^\tau} \text{id}\right) \# \rho_0$$

where $\alpha_k^\tau$ is defined inductively by

$$(\alpha_{k+1}^\tau - \alpha_k^\tau)(\alpha_{k+1}^\tau)^2 = 3\tau, \quad \alpha_0^\tau = \alpha_0$$

which is nothing but the implicit Euler discretization of the ODE

$$\alpha' \alpha^2 = 3, \quad \alpha(0) = \alpha_0,$$

whose solution is $\alpha(t) = (\alpha_0^3 + 9t)^{\frac{1}{3}}$. Extending $\rho_k^\tau$ in a piecewise constant way: $\rho^\tau(t) = \rho_{k+1}^\tau$ for $t \in (k\tau, (k + 1)\tau]$, it is not difficult to check that $\rho^\tau$ converges (in $L^\infty([0, T), (P_2(\mathbb{R}), W_2)$ and in $L^p((0, T) \times \mathbb{R})$ for any $p \in (1, \infty)$ and any $T > 0$) to $\rho$ given by $\rho(t, .) = \left(\frac{\alpha(t)}{\alpha_0} \text{id}\right) \# \rho_0$. Since $v(t, x) = \frac{\alpha(t)}{\alpha_0} x$ is the velocity field associated to $X(t, x) = \frac{\alpha(t)}{\alpha_0} x$, $\rho$ solves the continuity equation

$$\partial_t \rho + (\rho v)_x = 0.$$
In addition, \( \rho v = -\rho z_{xx} \) where
\[
z(t, x) = \frac{-\alpha'(t)}{6\alpha(t)} x^3 + \frac{3x}{2\alpha(t)}, \quad x \in [-\alpha(t), \alpha(t)],
\]
extended by 1 (respectively \(-1\)) on \([\alpha(t), +\infty)\) (respectively \((-\infty, -\alpha(t)]\)). The function \( z \) is \( C^1 \), \( \| z \|_{L^\infty} \leq 1 \) and \( z \cdot D\rho = -|D\rho| \) (in the sense of measures). In other words the limit \( \rho \) of \( \rho^\tau \) satisfies
\[
\partial_t \rho - (\rho z_{xx})_x = 0
\]
with \( |z| \leq 1 \) and \( z \cdot D\rho = -|D\rho| \) which is the natural weak form of (1.2).

### 2.2 Instantaneous creation of discontinuities

We now consider the case where \( \rho_0(x) = (1 - |x|)_+ \) and will show that the JKO scheme instantaneously creates a discontinuity at the level of \( \rho_1 \), the minimizer of \( \Phi_{\tau,\rho_0} \) when \( \tau \) is small enough. We indeed look for \( \rho_1 \) in the form:
\[
\rho_1(x) = \begin{cases} 
1 - \beta/2 & \text{if } |x| < \beta, \\
(1 - |x|)_+ & \text{if } |x| \geq \beta,
\end{cases}
\]
for some well-chosen \( \beta \in (0, 1) \). The optimal transport map \( T \) between such a \( \rho_1 \) and \( \rho_0 \) is odd and given explicitly by
\[
T(x) = \begin{cases} 
1 - \sqrt{1 - x(2 - \beta)} & \text{if } x \in [0, \beta), \\
x & \text{if } x \geq \beta.
\end{cases}
\]

The Kantorovich potential which vanishes at \( \beta \) (extended in an even way to \( \mathbb{R}_- \)) is then given by
\[
\varphi(x) = \begin{cases} 
\frac{x^2}{2} - x - \frac{(1-x(2-\beta))^{3/2}}{3(1-\beta/2)} + C & \text{if } x \in [0, \beta), \\
0 & \text{if } x > \beta,
\end{cases}
\]
where
\[
C = -\frac{\beta^2}{2} + \beta + \frac{2(1-\beta)^3}{3(2-\beta)}.
\]

Let us now integrate \( \tau z' = -\varphi \) on \([0, \beta]\) with initial condition \( z(0) = 0 \), i.e. for \( x \in [0, \beta] \)
\[
\tau z(x) = -\frac{x^3}{6} + \frac{x^2}{2} - \frac{4}{15(2-\beta)^2}[1 - (1 - 2\beta)x]^{5/2}
+ \left( \frac{\beta^2}{2} - \beta - \frac{2(1-\beta)^3}{3(2-\beta)} \right)x + \frac{4}{15(2-\beta)^2}
\]
6
Note that $z$ is nondecreasing on $[0, \beta]$ (because $\varphi(0) < 0$, $\varphi(\beta) = 0$ and $\varphi$ is convex on $[0, \beta]$ so that $\varphi \leq 0$ on $[0, \beta]$), our aim now is to find $\beta \in (0, 1)$ in such a way that $z(\beta) = 1$ i.e. replacing in the previous formula

$$\tau = \frac{\beta^3}{3} - \frac{\beta^2}{2} + \frac{4(1 - (1 - \beta)^5)}{15(2 - \beta)^2} - \frac{2(1 - \beta)^3\beta}{3(2 - \beta)}$$

the right hand-side is a continuous function of $\beta \in [0, 1]$ taking value 0 for $\beta = 0$ and $\frac{1}{10}$ for $\beta = 1$, hence as soon as $10\tau < 1$ one may find a $\beta \in (0, 1)$ such that indeed $z(\beta) = 1$. Extend then $z$ by 1 on $[\beta, +\infty)$ and to $\mathbb{R}_-$ in an odd way. We then have built a function $z$ which is $C^1$ ($\varphi(\beta) = 0$), such that $|z| \leq 1$, $z \cdot D\rho_1 = -|D\rho_1|$ and such that $z' + \frac{\varphi}{\tau} = 0$. Thanks to Lemma 2.1, we conclude that $\rho_1$ is optimal. This example shows that discontinuities may appear at the very first iteration of the TV-JKO scheme.

### 3 Maximum principle for JKO steps

Throughout this section, we assume that $\Omega$ is a convex open bounded subset of $\mathbb{R}^d$ and denote $\mathcal{P}_{ac}(\Omega)$ the set of Borel probability measures on $\Omega$ that are absolutely continuous with respect to the Lebesgue measure (and will use the same notation for $\mu \in \mathcal{P}_{ac}(\Omega)$ both for the measure $\mu$ and its density). Given $\rho_0 \in \mathcal{P}_{ac}(\Omega)$ and $\tau > 0$, we consider one step of the TV-JKO scheme:

$$\inf_{\rho \in \mathcal{P}_{ac}(\Omega)} \left\{ \frac{1}{2\tau} W_2^2(\rho_0, \rho) + J(\rho) \right\}. \quad (3.1)$$

It is easy by the direct method of the calculus of variations to see that (3.1) has at least one solution, moreover $J$ being convex and $\rho \mapsto W_2^2(\rho, \rho_0)$ being strictly convex whenever $\rho_0 \in \mathcal{P}_{ac}(\Omega)$ (see [28]), the minimizer is in fact unique, and in the sequel we denote it by $\rho_1$. 

Figure 1: The probability density functions $\rho_0$ and $\rho_1$ from section 2.2
3.1 Preliminaries

Our aim is to deduce some bounds on $\rho_1$ from bounds on $\rho_0$. To do so, we shall combine some convexity arguments and a remarkable BV estimate due to De Philippis et al. [12]. First we recall the notion of generalized geodesic from Ambrosio, Gigli and Savaré [2]. Given $\mu, \mu_0$ and $\mu_1$ in $\mathcal{P}_{ac}(\Omega)$, and denoting by $T_0$ (respectively $T_1$) the optimal transport (Brenier) map between $\mu$ and $\mu_0$ (respectively $\mu_1$), the generalized geodesic with base $\mu$ joining $\mu_0$ to $\mu_1$ is by definition the curve of measures:

$$
\mu_t := ((1-t)T_0 + tT_1)_{#} \mu, \ t \in [0,1].
$$

(3.2)

A key property of these curves introduced in [2] is the strong convexity of the squared distance estimate:

$$
W_2^2(\mu, \mu_t) \leq (1-t)W_2^2(\mu, \mu_0) + tW_2^2(\mu, \mu_1) - t(1-t)W_2^2(\mu_0, \mu_1).
$$

(3.3)

It is well-known that if $G : \mathbb{R}_+ \to \mathbb{R} \cup \{+\infty\}$ is a proper convex lower semi-continuous (l.s.c.) internal energy density, bounded from below such that $G(0) = 0$ and which satisfies McCann’s condition (see [25])

$$
\lambda \in \mathbb{R}_+ \to \lambda^d G(\lambda^{-d}) \text{ is convex nonincreasing}
$$

(3.4)

then defining the generalized geodesic curve $(\mu_t)_{t \in [0,1]}$ by (3.2), one has

$$
\int_{\Omega} G(\mu_t(x))dx \leq (1-t)\int_{\Omega} G(\mu_0(x))dx + t\int_{\Omega} G(\mu_1(x))dx.
$$

(3.5)

In particular $L^p$ and uniform bounds are stable along generalized geodesics:

$$
\|\mu_t\|_{L^p} \leq (1-t)\|\mu_0\|_{L^p} + t\|\mu_0\|_{L^p}, \ \|\mu_t\|_{L^\infty} \leq \max(\|\mu_0\|_{L^\infty}, \|\mu_1\|_{L^\infty}),
$$

(3.6)

and

$$
\int_{\Omega} \mu_t(x) \log(\mu_t(x))dx \leq (1-t)\int_{\Omega} \mu_0(x) \log(\mu_0(x))dx + t\int_{\Omega} \mu_1(x) \log(\mu_1(x))dx.
$$

(3.7)

An immediate consequence of (3.3) (see chapter 4 of [2] for general contraction estimates) is the following

**Lemma 3.1.** Let $K$ be a nonempty subset of $\mathcal{P}_{ac}(\Omega)$, let $\mu_0 \in K, \mu_1 \in \mathcal{P}_{ac}(\Omega)$, if $\tilde{\mu}_1 \in \arg\min_{\mu \in K} W_2^2(\mu_1, \mu)$ and if the generalized geodesic with base $\mu_1$ joining $\mu_0$ to $\tilde{\mu}_1$ remains in $K$ then

$$
W_2^2(\mu_0, \mu_1) \leq W_2^2(\mu_0, \mu_1) - W_2^2(\mu_1, \tilde{\mu}_1).
$$

(3.8)
Proof. Since $\mu_t \in K$ we have $W_2^2(\mu_1, \hat{\mu}_1) \leq W_2^2(\mu_1, \mu_t)$, applying (3.3) to the generalized geodesics with base $\mu_1$ joining $\mu_0$ to $\mu_1$ we thus get

$$(1 - t)W_2^2(\mu_1, \hat{\mu}_1) \leq (1 - t)W_2^2(\mu_1, \mu_0) - t(1 - t)W_2^2(\mu_0, \hat{\mu}_1),$$

dividing by $(1 - t)$ and then taking $t = 1$ therefore gives the desired result.

The other result we shall use to derive bounds is a BV estimate of De Philippis et al. [12], which states that given $\mu, \in P_{ac}(\Omega) \cap BV(\Omega)$, and $G : \mathbb{R}_+ \to \mathbb{R} \cup \{+\infty\}$, proper convex l.s.c., the solution of

$$\inf_{\rho \in P_{ac}(\Omega)} \left\{ \frac{1}{2}W_2^2(\mu, \rho) + \int_{\Omega} G(\rho(x))\,dx \right\}$$

is BV with the bound

$$J(\rho) \leq J(\mu).$$

(3.10)

Taking in particular,

$$G(\rho) := \begin{cases} 0 & \text{if } \rho \leq M, \\ +\infty & \text{otherwise,} \end{cases}$$

this implies that the Wasserstein projection of $\mu$ onto the set defined by the constraint $\rho \leq M$ has a smaller total variation than $\mu$.

### 3.2 Maximum and minimum principles

**Theorem 3.2.** Let $\rho_0 \in P_{ac}(\Omega) \cap L^\infty(\Omega)$ and let $\rho_1$ be the solution of (3.1), then $\rho_1 \in L^\infty(\Omega)$ with

$$\|\rho_1\|_{L^\infty(\Omega)} \leq \|\rho_0\|_{L^\infty(\Omega)}. \quad \text{(3.11)}$$

Proof. Thanks to (3.6) the set $K := \{ \rho \in P_{ac}(\Omega) \cap L^p(\Omega) : \rho \leq \|\rho_0\|_{L^\infty(\Omega)} \text{ a.e.} \}$ has the property that the generalized geodesics (with any base) joining two of its points remains in $K$. Let then $\hat{\rho}_1$ be the $W_2$ projection of $\rho_1$ onto $K$ i.e. the solution of $\inf_{\rho \in K} W_2^2(\rho_1, \rho)$. Thanks to Lemma 3.1 we have $W_2^2(\rho_0, \hat{\rho}_1) \leq W_2^2(\rho_0, \rho_1) - W_2^2(\rho_1, \hat{\rho}_1)$ and thanks to Theorem 1.1 of [12], $J(\hat{\rho}_1) \leq J(\rho_1)$. The optimality of $\rho_1$ for (3.1) therefore implies $W_2(\rho_1, \hat{\rho}_1) = 0$ i.e. $\rho_1 \leq \|\rho_0\|_{L^\infty(\Omega)}$. 

Remark 3.3. In section 4, we shall use an approximation of (3.1) with an additional small entropy term, the same bound as in Theorem 3.2 will remain valid in this case. Indeed, consider a proper convex l.s.c. and bounded from below internal energy density $G$ and consider given $h \geq 0$, the variant of (3.1)

$$
\inf_{\rho \in P_{ac}(\Omega)} \left\{ \frac{1}{2\tau} W_2^2(\rho_0, \rho) + J(\rho) + h \int_{\Omega} G(\rho(x)) dx \right\}. \quad (3.12)
$$

Then we claim that the solution $\rho_h$ still satisfies $\rho_h \leq \|\rho_0\|_{L^\infty(\Omega)}$. Indeed, we have seen in the previous proof that the Wasserstein projection $\hat{\rho}_h$ of $\rho_h$ onto the constraint $\rho \leq \|\rho_0\|_{L^\infty(\Omega)}$ both diminishes $J$ and the Wasserstein distance to $\rho_0$. It turns out that it also diminishes the internal energy. Indeed, thanks to Proposition 5.2 of [12], there is a measurable set $A$ such that

$$
\hat{\rho}_h = \chi_A \rho_h + \chi_{\Omega \setminus A} \|\rho_0\|_{L^\infty}.
$$

So, from the convexity of $G$ and Jensen’s inequality,

$$
\int G(\hat{\rho}_h) = \int_A G(\rho_h) + |\Omega \setminus A| G \left( |\Omega \setminus A|^{-1} \int_{\Omega \setminus A} \rho_h \right) \leq \int G(\rho_h),
$$

thus yielding the same conclusion as above.

In dimension one, it turns out that we can similarly obtain bounds from below:

**Proposition 3.4.** Assume that $d = 1$, that $\Omega$ is a bounded interval and that $\rho_0 \geq \alpha > 0$ a.e. on $\Omega$ then the solution $\rho_1$ of (3.1) also satisfies $\rho_1 \geq \alpha > 0$ a.e. on $\Omega$.

**Proof.** The proof is similar to that of Theorem 3.2 but using the Wasserstein projection on the set $K := \{ \rho \in P_{ac}(\Omega) : \rho \geq \alpha \}$, the only thing to check to be able to use Lemma 3.1 is that for any basepoint $\mu$ and any $\mu_0$ and $\mu_1$ in $K$, the generalized geodesic with base point $\mu$ joining $\mu_0$ to $\mu_1$ remains in $K$. The optimal transport maps $T_0$ and $T_1$ from $\mu$ to $\mu_0$ and $\mu_1$ respectively are nondecreasing and continuous and setting $T_t := (1-t)T_0 + tT_1$, one has

$$
\mu = \mu_t(T_t) T_t' = \mu_0(T_0) T_0' = \mu_1 T_1 = (1-t)\mu_0(T_0) T_0' + t\mu_1(T_1) T_1' \geq \alpha T_t'
$$

which is easily seen to imply that $\mu_t \geq \alpha$ a.e.

\[ \square \]

### 4 Euler-Lagrange equation for JKO steps

The aim of this section is to establish optimality conditions for (3.1). Despite the fact that it is a convex minimization problem, it involves two nonsmooth
terms $J$ and $W_2^2(\rho_0, \cdot)$, so some care should be taken of to justify rigorously the arguments. In the next section, we introduce an entropic regularization approximation, the advantage of this strategy is that the minimizer will be positive everywhere, giving some differentiability of the transport term.

### 4.1 Entropic approximation

In this whole section we assume that $\Omega$ is an open bounded connected subset of $\mathbb{R}^d$ with Lipschitz boundary and that $\rho_0 \in P_{ac}(\Omega)$. Given $h > 0$ we consider the following approximation of (3.1):

$$
\inf_{\rho \in P(\Omega)} \left\{ F_h(\rho) := \frac{1}{2\tau} W_2^2(\rho_0, \rho) + J(\rho) + hE(\rho) \right\} \tag{4.1}
$$

where

$$
E(\rho) := \int_{\Omega} \rho(x) \log(\rho(x)) dx.
$$

It is easy to see that (4.1) admits a unique solution $\rho_h$ and since $J(\rho_h)$ is bounded, up to a subsequence of vanishing $h$’s, one may assume that $\rho_h$ converges as $h \to 0$ a.e. and strongly in $L^p(\Omega)$ for every $p \in [1, \frac{d}{d-1})$ to $\rho_1$ the solution of (3.1).

We first have a bound from below on $\rho_h$:

**Lemma 4.1.** There is an $\alpha_h > 0$ such that $\rho_h \geq \alpha_h$ a.e..

**Proof.** Assume on the contrary that $|\rho| \leq \alpha$ for every $\alpha > 0$. For small $\varepsilon \in (0, 1)$ set $\mu_{\varepsilon,h} := \max((1 - \sqrt{\varepsilon})\rho_h + \varepsilon, \rho_h)$ that is $(1 - \sqrt{\varepsilon})\rho_h + \varepsilon$ on $A_{\varepsilon,h} := \{\rho_h \leq \sqrt{\varepsilon}\}$ and $\rho_h$ elsewhere. Define

$$
c_{\varepsilon,h} := \int_{\Omega} (\mu_{\varepsilon,h} - \rho_h)
$$

and observe that $c_{\varepsilon,h} \leq \varepsilon|\Omega| \leq \sqrt{\varepsilon}|\Omega|$. Now chose $M_h > 0$ such that $V_h := \{\rho_h > M_h\}$ has positive Lebesgue measure and finite perimeter (recall that $\rho_h$ is BV) and chose $\varepsilon$ small enough so that

$$
\sqrt{\varepsilon} \leq \frac{M_h|V_h|}{2|\Omega|}. \tag{4.2}
$$

Note that (4.2) implies that $c_{\varepsilon,h} \leq \frac{1}{2}M_h|V_h|$ and $M_h > \sqrt{\varepsilon}$ (so that $A_{\varepsilon,h}$ and $V_h$ are disjoint). Finally, define

$$
\rho_{\varepsilon,h} := \mu_{\varepsilon,h} - c_{\varepsilon,h} \frac{V_h}{|V_h|}.
$$

By construction $\rho_{\varepsilon,h} \in P(\Omega)$ hence $0 \leq F_h(\rho_{\varepsilon,h}) - F_h(\rho_h)$, in this difference we have four terms, namely
• the Wasserstein term, which, using the Kantorovich duality formula (2.1) and the fact that $\Omega$ is bounded can be estimated in terms of $\|\rho_{\varepsilon,h} - \rho_h\|_{L^1} = 2c_{\varepsilon,h}$:

$$\frac{1}{2\tau} W^2_2(\rho_{\varepsilon,h}, \bar{\rho}) - \frac{1}{2\tau} W^2_2(\rho_h, \bar{\rho}) \leq \frac{C}{\tau} c_{\varepsilon,h}. \quad (4.3)$$

for a constant $C$ that depends on $\Omega$ but neither on $\varepsilon$ nor $h$,

• the TV term: $J(\rho_{\varepsilon,h}) - J(\rho_h)$: outside $V_h$ we have replaced $\rho_h$ by a 1-Lipschitz function of $\rho_h$ which decreases the TV semi-norm, on $V_h$ on the contrary we have created a jump of magnitude $c_{\varepsilon,h}/|V_h|$ so

$$J(\rho_{\varepsilon,h}) - J(\rho_h) \leq \frac{\text{Per}(V_h)}{|V_h|} \quad (4.4)$$

where $\text{Per}(V_h) = J(\chi_{V_h})$ denotes the perimeter of $V_h$ (in $\Omega$),

• the entropy variation on $A_{\varepsilon,h}$, on this set both $\rho_{\varepsilon,h}$ and $\rho_h$ are less than $\sqrt{\varepsilon}$ so that $(1 + \log(t)) \leq (1 + \log(\sqrt{\varepsilon}))$ whenever $t \in [\rho_h, \rho_{\varepsilon,h}]$ which by the mean value theorem yields

$$\int_{A_{\varepsilon,h}} (\rho_{\varepsilon,h} \log(\rho_{\varepsilon,h}) - \rho_h \log(\rho_h)) \leq (1 + \log(\sqrt{\varepsilon})) c_{\varepsilon,h} \quad (4.5)$$

• the entropy variation on $V_h$, but on $V_h$, if $\rho_{\varepsilon,h} \geq \frac{1}{e}$ then $(\rho_{\varepsilon,h} \log(\rho_{\varepsilon,h}) - \rho_h \log(\rho_h)) \leq 0$, we then observe that the remaining set $V_h \cap \{\rho_{\varepsilon,h} \leq \frac{1}{e}\} \subset \{\rho_h \leq \frac{1}{e} + \frac{M_h}{2}\}$ so that both $\rho_{\varepsilon,h}$ and $\rho_h$ are bounded away from 0 and infinity on this set so remain in an interval where $t \log(t)$ is Lipschitz with Lipschitz constant at most

$$C_h(M_h) := \max \left\{ \left| 1 + \log(t) \right| : \frac{M_h}{2} \leq t \leq \frac{1}{e} + \frac{M_h}{2} \right\}. \quad (4.6)$$

we thus have

$$\int_{V_h} (\rho_{\varepsilon,h} \log(\rho_{\varepsilon,h}) - \rho_h \log(\rho_h)) \leq C_h(M_h) c_{\varepsilon,h}. \quad (4.7)$$

Putting together (4.3)-(4.4)-(4.5)-(4.7), we arrive at

$$0 \leq \left( \frac{C}{\tau} + \frac{\text{Per}(V_h)}{|V_h|} + hC_h(M_h) + h \log(\sqrt{\varepsilon}) + h \right) c_{\varepsilon,h}$$

12
which for small enough $\varepsilon$ is possible only when $c_{\varepsilon,h} = 0$ i.e. $|A_{\varepsilon,h}| = 0$. More precisely, either we have the lower bound:

$$
    h \log(\rho_h) \geq -\frac{C}{\tau} - hC_h(M_h) - \frac{\text{Per}(V_h)}{|V_h|} - h
$$

(4.8)
or (4.2) is impossible i.e.

$$
    \rho_h \geq \frac{M_h|V_h|}{2|\Omega|}.
$$

(4.9)

We actually also have uniform bounds with respect to $h$:

**Lemma 4.2.** The family $\theta_h := -h \log(\rho_h)$ is (up to a subsequence) uniformly bounded from above. Moreover, $\theta_h$ is bounded in $L^p(\Omega)$ for any $p > 1$.

**Proof.** In view of (4.6), (4.8) and (4.9), it is enough to show that we can find a family $M_h$, bounded and bounded away from 0, such that setting $V_h := \{\rho_h > M_h\}$, $|V_h|$ remains bounded away from 0, and $\text{Per}(V_h)$ is uniformly bounded from above as $h \to 0$. First note that, since $J(\rho_h)$ is bounded, there exists $\rho$ such that $\rho_h \to \rho$ in $L^1$ and a.e. up to a subsequence, note also that $\rho \in \text{BV}$ and $\rho$ is a probability density. Setting $F^h := \{\rho_h > t\}$ and $F_t := \{\rho > t\}$, it is easy to deduce from Fatou’s Lemma that when $s > t$, $\liminf_{h} |F^h_t| \geq |F_t|$, hence choosing $0 < \beta_1 < \beta_2 < \beta$ so that $|F_\beta| > 0$ we have that there exists $h_0 > 0$ and $c_1 > 0$ such that for all $t \in [\beta_1, \beta_2]$

$$
    c_1 \leq |F^h_t| \leq |\Omega|
$$

whenever $0 < h < h_0$. Also, since $J(\rho_h) \leq C$, by the co-area formula

$$
    \int_{\beta_1}^{\beta_2} \text{Per}(F^h_t) dt \leq J(\rho_h) \leq C.
$$

So, there exists $t_h \in [\beta_1, \beta_2]$ such that $\text{Per}(F^h_{t_h}) \leq C/(\beta_2 - \beta_1)$. Therefore, it suffices to choose $M_h = t_h$ and $V_h = F^h_{t_h}$.

We may assume that $\rho_h \leq \phi$ for some $\phi \in L^1$, then by Dominated convergence and since $\log(\max(\phi, 1)) \in L^p(\Omega)$ for every $p > 1$, we have that $\log(\max(\rho_h, 1))$ converges a.e. and in $L^p$, in particular this implies that $\max(0, -\theta_h)$ converges to 0 strongly in $L^p(\Omega)$, and we have just seen that $\max(0, \theta_h)$ is bounded in $L^\infty(\Omega)$.

\[\square\]
Let us also recall some well-known facts (see [9]) about the total variation functional $J$ viewed as a convex l.s.c. and one-homogeneous functional on $L^p(\Omega)$. Define

$$
\Gamma_d := \{ \xi \in L^d(\Omega) : \exists z \in L^\infty(\Omega, \mathbb{R}^d), \|z\|_{L^\infty} \leq 1, \text{ div}(z) = \xi, \ z \cdot \nu = 0 \text{ on } \partial \Omega \} \quad (4.10)
$$

where div($z$) = $\xi$, $z \cdot \nu = 0$ on $\partial \Omega$ are to be understood in the weak sense

$$
\int_{\Omega} \xi u = - \int_{\Omega} z \cdot \nabla u, \ \forall u \in C^1(\Omega).
$$

Note that $\Gamma_d$ is closed and convex in $L^d(\Omega)$ and $J$ is its support function:

$$
J(\mu) = \sup_{\xi \in \Gamma_d} \int_{\Omega} \xi \mu, \ \forall \mu \in L^{\frac{d}{d-1}}(\Omega). \quad (4.11)
$$

As for the Wasserstein term, recalling Kantorovich dual formulation (2.1), the derivative of the Wasserstein term $\rho \mapsto W_2^2(\rho_0, \rho)$ term will be expressed in terms of a Kantorovich potential between $\rho$ and $\rho_0$.

We then have the following characterization for $\rho_h$:

**Proposition 4.3.** There exists $z_h \in L^\infty(\Omega, \mathbb{R}^d)$ such that div($z_h$) $\in L^p(\Omega)$ for every $p \in [1, +\infty)$, $\|z_h\|_{L^\infty} \leq 1$, $z_h \cdot \nu = 0$ on $\partial \Omega$, $J(\rho_h) = \int_{\Omega} \text{div}(z_h)\rho_h$ and

$$
\frac{\varphi_h}{\tau} + \text{div}(z_h) + h \log(\rho_h) = 0, \ a.e. \ in \ \Omega \quad (4.12)
$$

where $\varphi_h$ is the Kantorovich potential between $\rho_h$ and $\rho_0$.

**Proof.** Let $\mu \in L^\infty(\Omega) \cap \text{BV}(\Omega)$ such that $\int_{\Omega} \mu = 0$. Thanks to Lemma 4.1, we know that $\rho_h$ is bounded away from 0 hence for small enough $t > 0$, $\rho_h + t\mu$ is positive hence a probability density. Also, as a consequence of Theorem 1.52 in [28], we have that

$$
\lim_{t \to 0^+} \frac{1}{2t} [W_2^2(\rho_0, \rho_h + t\mu) - W_2^2(\rho_0, \rho_h)] = \int_{\Omega} \varphi_h \mu \quad (4.13)
$$

where $\varphi_h$ is the (unique up to an additive constant) Kantorovich potential between $\rho_h$ and $\rho_0$, in particular $\varphi_h$ is Lipschitz and semi concave ($D^2 \varphi_h \leq \text{id}$ in the sense of measures and $\text{id} - \nabla \varphi_h$ is the optimal transport between $\rho_h$ and $\rho_1$). By the optimality of $\rho_h$ and the fact that $J$ is a semi-norm, we get

$$
J(\mu) \geq J(\rho_h + \mu) - J(\rho_h) \geq \lim_{t \to 0^+} t^{-1}(J(\rho_h + t\mu) - J(\rho_h)) \geq \int_{\Omega} \xi_h \mu, \quad (4.14)
$$

14
where

$$\xi_h := -\frac{\varphi_h}{\tau} - h \log(\rho_h).$$

Since $\varphi_h$ is defined up to an additive constant, we may choose it in such a way that $\xi_h$ has zero mean, doing so, (4.14) holds for any $\mu \in L^\infty(\Omega) \cap BV(\Omega)$ (not necessarily with zero mean). Being Lipschitz, $\varphi_h$ is bounded, also observe that $h(\log(\rho_h))_+ = h \log(\max(1, \rho_h))$ is in $L^p(\Omega)$ for every $p \in [1, +\infty)$ since $\rho_h \in L^\frac{d}{d-1}(\Omega)$ and $h \log(\rho_h)_- = -h \log(\min(1, \rho_h))$ is $L^\infty(\Omega)$ thanks to Lemma 4.1, hence we have $\xi_h \in L^p(\Omega)$ for every $p \in [1, +\infty)$.

By approximation and observing that $\xi_h \in L^d(\Omega)$, (4.14) extends to all $\mu \in L^d(\Omega)$. In particular, we have

$$\sup_{\xi \in \Gamma_d} \int_{\Omega} \xi \mu \geq \int_{\Omega} \xi_h \mu$$

but since $\Gamma_d$ is convex and closed in $L^d(\Omega)$, it follows from Hahn-Banach’s separation theorem that $\xi_h \in \Gamma_d$. Finally, getting back to (4.14) (without the zero mean restriction on $\mu$) and taking $\mu = -\rho_h$ gives $J(\rho_h) \leq \int_{\Omega} \xi_h \rho_h$, and we then deduce that this should be an equality.

4.2 Euler-Lagrange equation

We are now in position to rigorously establish the Euler-Lagrange equation for (3.1):

**Theorem 4.4.** If $\rho_1$ solves (3.1), there exists $\varphi$ a Kantorovich potential between $\rho_0$ and $\rho_1$ (in particular $\text{id} - \nabla \varphi$ is the optimal transport between $\rho_1$ and $\rho_0$), $\beta \in L^\infty(\Omega)$, $\beta \geq 0$ and $z \in L^\infty(\Omega, \mathbb{R}^d)$ such that

$$\frac{\varphi}{\tau} + \text{div}(z) = \beta, \ z \cdot \nu = 0 \text{ on } \partial \Omega, \quad (4.15)$$

and

$$\beta \rho_1 = 0, \quad \|z\|_{L^\infty} \leq 1, \quad J(\rho_1) = \int_{\Omega} \text{div}(z) \rho_1. \quad (4.16)$$

**Proof.** As in section 4.1, we denote by $\rho_h$ the solution of the entropic approximation (4.1). Up to passing to a subsequence (not explicitly written), we may assume that $\rho_h$ converges a.e. and strongly in $L^p(\Omega)$ (for any $p \in [1, \frac{d}{d-1}]$) to $\rho_1$. We then rewrite the Euler-Lagrange equation from Proposition 4.3 as

$$\frac{\varphi_h}{\tau} + \text{div}(z_h) + \beta^+_h = \beta^-_h, \quad (4.17)$$
where $\beta^+_h := h \log(\max(\rho_h, 1))$, $\beta^-_h := -h \log(\min(\rho_h, 1))$, and

$$
\|z_h\|_{L^\infty} \leq 1, \ z_h \cdot \nu = 0 \text{ on } \partial \Omega \text{ and } J(\rho_h) = \int_\Omega \text{div}(z_h)\rho_h.
$$

(4.18)

It is easy to see that $\beta^+_h$ converges to 0 strongly in any $L^q$, $q \in [1, +\infty)$ and it follows from Lemma 4.2 that $\beta^-_h$ is bounded in $L^\infty$. Up to subsequences, we may therefore assume that $z_h$ and $\beta^-_h$ weakly-* converge in $L^\infty$ respectively to some $z$ and $\beta$ with $\|z\|_{L^\infty} \leq 1$, $z \cdot \nu = 0$ on $\partial \Omega$ and $\beta \geq 0$. As for $\varphi_h$, it is an equi-Lipschitz family and $\int_\Omega \varphi_h = \tau \int_\Omega (\beta^-_h - \beta^+_h)$ which remains bounded, hence we may assume that $\varphi_h$ converges uniformly to some potential $\varphi$ and it is well-known (see [28]) that $\varphi$ is a Kantorovich potential between $\rho_1$ and $\rho_0$. Letting $h$ tends to 0 gives (4.15).

Since $\rho_h$ converges strongly in $L^1$ to $\rho_1$ and $\beta^-_h$ converges weakly-* to $\beta$ in $L^\infty$ we have

$$
\int_\Omega \rho_1 \beta = \lim_h \int_\Omega \rho_h \beta^-_h = \lim_h \int_\Omega \rho_h |\log(\min(1, \rho_h))| = 0,
$$

hence $\beta \rho_1 = 0$. Thanks to (4.11), we obviously have $J(\rho_1) \geq \int_\Omega \text{div}(z)\rho_1$, for the converse inequality, it is enough to observe that

$$
J(\rho_1) \leq \liminf_h J(\rho_h) = \liminf_h \int_\Omega \text{div}(z_h)\rho_h
$$

and that $\text{div}(z_h) = -\frac{z_h}{\tau} - \beta^+_h + \beta^-_h$ converges to $\text{div}(z)$ weakly in $L^q$ for every $q \in [1, +\infty)$. Since $\rho_h$ converges strongly to $\rho_1$ in $L^q$ when $q \in [1, \frac{d}{d-1})$ we deduce that $J(\rho_1) = \int_\Omega \text{div}(z)\rho_1$ which completes the proof of (4.16).

Remark 4.5. It is not difficult (since (3.1) is a convex problem) to check that (4.15)-(4.16) are also sufficient optimality conditions. The main point here is that the right hand side $\beta$ in (4.15) which is a multiplier associated with the nonnegativity constraint is better than a measure, it is actually an $L^\infty$ function.

In dimension 1, we can integrate the Euler-Lagrange equation and then deduce higher regularity for the dual variable $z$:

**Corollary 4.6.** Assume that $d = 1$ and $\Omega$ is a bounded interval. If $\rho_1$ solves (3.1) and $z$ is as in Theorem 4.4 then $z \in W^{1,\infty}_0(\Omega)$. If in addition $\rho_0 \geq \alpha > 0$ a.e. on $\Omega$, then $z \in W^{3,\infty}(\Omega)$. 

16
Proof. The first claim is obvious because both $\varphi$ and $\beta$ are bounded hence so is $z'$. As for the second one when $\rho_0 \geq \alpha > 0$, thanks to Proposition 3.4, we also have $\rho_1 \geq \alpha$ hence $\beta = 0$ in (4.15) and in this case $\text{div}(z) = z' = -\frac{x}{r}$ is Lipschitz i.e. $z \in W^{2,\infty}$. One can actually go one step further because $x - \varphi'(x) = T(x)$ where $T$ is the optimal (monotone) transport between $\rho_1$ and $\rho_0$. This map is explicit in terms of the cumulative distribution function of $\rho_1$, $F_1$, and $F_0^{-1}$ the inverse of $F_0$, the cumulative distribution function of $\rho_0$, namely $T = F_0^{-1} \circ F_1$. But $F_1$ is Lipschitz since its derivative is $\rho_1$ which is BV hence bounded and $F_0^{-1}$ is Lipschitz as well since $\rho_0 \geq \alpha > 0$. This gives that $\varphi \in W^{2,\infty}$ hence $z \in W^{3,\infty}$.

5 Regularity of level sets

We discuss in this section how the fact that $\text{div}(z) \in L^\infty$ in Theorem 4.4 allows for conclusions about the regularity of the level sets of $\rho_1$, the solution of (3.1). A first consequence of the high integrability of $\text{div}(z)$ is that one can give a meaning to $z \cdot \nabla u$ for any $u \in \text{BV}(\Omega)$. Indeed, following Anzellotti [3], if $u \in \text{BV}(\Omega)$ and $\sigma \in L^\infty(\Omega, \mathbb{R}^d)$ is such that $\text{div}(\sigma) \in L^d(\Omega)$, one can define the distribution $\sigma \cdot Du$ by

$$\langle \sigma \cdot Du, v \rangle = -\int_{\Omega} \text{div}(\sigma) uv - \int_{\Omega} u \sigma \cdot \nabla v, \forall v \in C^1_c(\Omega).$$

Then $\sigma \cdot Du$ is a Radon measure which satisfies $|\sigma \cdot Du| \leq \|\sigma\|_{L^\infty} |Du|$ (in the sense of measures) hence is absolutely continuous with respect to $|Du|$. Moreover one can also define a weak notion of normal trace of $\sigma$, $\sigma \cdot \nu \in L^\infty(\partial \Omega)$ such that the following integration by parts formula holds

$$\int_{\Omega} \sigma \cdot Du = -\int_{\Omega} \text{div}(\sigma) u + \int_{\partial \Omega} u(\sigma \cdot \nu).$$

We refer to [3] for proofs. These considerations of course apply to $\sigma = z$ and $u = \rho_1 \in \text{BV}(\Omega)$ and in particular enable one to see $z \cdot D\rho_1$ as a measure and to interpret the optimality condition $J(\rho_1) = \int_{\Omega} \text{div}(z)\rho_1$ as $|D\rho_1| = -z \cdot D\rho_1$ in the sense of measures.

It now follows from Proposition 3.3 of [10], that every (not only almost every) level set $F_t = \{\rho_1 > t\}$ with $t > 0$ satisfies

$$\text{Per}(F_t) = \int_{F_t} \text{div}(z) \text{ and } F_t \in \text{argmin}_{G \subset \Omega} \left\{ \text{Per}(G) - \int_G \text{div}(z) \right\}. \quad (5.1)$$

This means that $-\text{div}(z)$ is the variational mean curvature of $F_t$. Indeed, recall, following Gonzalez and Massari [21], that a set of finite perimeter
$E \subset \Omega \subset \mathbb{R}^d$ is said to have variational mean curvature $g \in L^1(\Omega)$ precisely when $E$ minimizes
\[
\min_{F \subset \Omega} \text{Per}(F) + \int_F g. \tag{5.2}
\]

Regularity of sets with an $L^p$ variational mean curvature, in connection with the so-called quasi-minimizers of the perimeter has been extensively studied, see Tamanini [29], Massari [22, 23], Theorem 3.6 of [21] and Maggi’s book [20]. It follows from the results of [29] that if $E$ has variational mean curvature $g \in L^p(\Omega)$ with $p \in (d, +\infty]$, then its reduced boundary (see [1]) $\partial^* E$ is a $(d - 1)$-dimensional manifold of class $C^{1,\frac{d}{2p}}$ and $\mathcal{H}^s((\partial E \setminus \partial^* E) \cap \Omega) = 0$ for all $s > d - 8$. We thus deduce from Theorem 4.4:

**Theorem 5.1.** If $\rho_1$ solves (3.1), then for every $t > 0$, the level set $F_t = \{\rho_1 > t\}$ has the property that its reduced boundary, $\partial^* F_t$ is a $C^{1,\frac{1}{2}}$ hypersurface and $(\partial F_t \setminus \partial^* F_t) \cap \Omega$ has Hausdorff dimension less than $d - 8$.

Finally, the question of whether one can assign a pointwise geometric meaning to $z \cdot D\chi_E$ was addressed by Chambolle, Goldman and Novaga in [11]. In dimensions $d = 2$ and $d = 3$, it is indeed proved in [11] that if $g = -\text{div}(z) \in L^d(\Omega)$ and $E$ minimizes (5.2), then any point $x \in \partial^* E$ is a Lebesgue point of $z$ and $z(x) = \nu_E(x)$ where $\nu_E$ is the unit outward normal to $\partial^* E$.

### 6 The case of step functions

As another illustration of the results of section 4, we have the following result concerning step-functions in dimension one:

**Theorem 6.1.** Let $d = 1$, $\Omega = (a, b)$ and $\rho_0$ be a step function with at most $N$-discontinuities i.e.:
\[
\rho_0 := \sum_{j=0}^N \alpha_j \chi_{[a_j, a_{j+1})}, \quad a_0 = a < a_1 < \cdots < a_N < a_{N+1} = b, \tag{6.1}
\]
then the solution $\rho_1$ of (3.1) is also a step function with at most $N$ discontinuities.

**Proof. Step 1: reduction to the positive case** We first claim that we may reduce ourselves to the case where $\rho_0 \geq \alpha > 0$ (so that $\rho_1 \geq \alpha > 0$ as well by virtue of Proposition 3.4). Indeed, assume that the statement of Theorem 6.1 holds under the additional assumption that $\alpha := \min(\alpha_0, \cdots, \alpha_N) > 0$. 

18
Then, setting for every integer \( n \geq 1 \), \( \rho^n_0 := \frac{1}{n} + (1 - \frac{1}{n})\rho_0 \), the corresponding solution of \((3.1)\), \( \rho^n_1 \) will also be a step function with at most \( N \) discontinuities. It is clear that up to a subsequence, \( \rho^n_1 \) converges strongly in \( L^1 \) as \( n \to \infty \) and a.e. to \( \rho_1 \) which thus also has to be a step function with at most \( N \) discontinuities. We therefore assume from now on that \( \rho_0 \) and \( \rho_1 \) are everywhere positive.

**Step 2 : \( \rho_1 \) is a jump function.** Thanks to Theorem 4.4 and Corollary 4.6, there is a \( z \in W^{3,\infty} \) such that \( z(a) = z(b) = 0, |z| \leq 1 \) and a Kantorovich potential \( \varphi \) such that

\[
z' + \frac{\varphi}{\tau} = 0, \quad \varphi'(x) = x - T(x), \tag{6.2}
\]

where \( T \) is the optimal (monotone nondecreasing) transport between \( \rho_1 \) and \( \rho_0 \):

\[
F_0 \circ T = F_1, \quad F_0(x) := \int_a^x \rho_0, \quad F_1(x) := \int_a^x \rho_1, \tag{6.3}
\]

(note that \( T \) is a bi-Lipschitz homeomorphism) and

\[
J(\rho_1) = \int_a^b z' \rho_1 = -\int_a^b z \cdot D\rho_1 = |D\rho_1|(a,b)
\]

where \( D\rho_1 \) is the (signed measure) distributional derivative of \( \rho_1 \). Observe also that from (6.2) points at which \( z'' \) vanish are fixed points of \( T \).

We then perform a Hahn-Jordan decomposition of \( D\rho_1 \):

\[
D\rho_1 = \mu^+ - \mu^-, \quad \mu^+ \geq 0, \quad \mu^- \geq 0, \quad \mu^+ \perp \mu^- \tag{6.4}
\]

and set

\[
A := \text{spt}(|D\rho_1|) = A^+ \cup A^- \text{ with } A^+ := \text{spt}(\mu^+), \quad A^- := \text{spt}(\mu^-). \tag{6.5}
\]

Next, noting that \( |D\rho_1| = \mu^+ + \mu^- = -z(\mu^+ - \mu^-) \), we deduce that \( z = -1 \) \( \mu^+ \)-a.e and since \( z \) is continuous we should have \( z = -1 \) on \( A^+ = \text{spt}(\mu^+) \).

In a similar way, \( z = 1 \) on \( A^- := \text{spt}(\mu^-) \), it implies in particular that the compact sets \( A^+ \) and \( A^- \) are disjoint so that the distance between \( A^+ \) and \( A^- \) is positive. Note also that since \( z \) is \( C^2 \), minimal on \( A^+ \) and maximal on \( A^- \) we have (also see [10] for a similar discussion):

\[
z' = 0 \text{ on } A, \quad z'' \geq 0 \text{ hence } T \geq \text{id on } A^+, \text{ and } z'' \leq 0 \text{ hence } T \leq \text{id on } A^- \tag{6.6}
\]

Since \( z' = 0 \) on \( A \), it follows from Rolle’s Theorem that if \( a < x < y < b \) with \( x, y \in A \times A \), there exists \( c \in (x, y) \) such that \( z''(c) = 0 \) i.e. \( T(c) = c \). In
particular $T = \text{id}$ on the set of limit points of $A$. We now further decompose $\mu^\pm$ in its purely atomic and nonatomic parts:

$$
\mu^\pm = \sum_{x \in J^\pm} \mu^\pm(\{x\}) \delta_x + \tilde{\mu}^\pm,
$$

(6.7)

where $J^\pm$ is the (finite or countable) set of atoms of $\mu^\pm$ and $\tilde{\mu}^\pm$ has no atom. Our aim is to show that the sets

$$
\tilde{A}^\pm := \text{spt}(\tilde{\mu}^\pm),
$$

(6.8)

are empty. Assume on the contrary that $\tilde{A}^+ \neq \emptyset$, then since all points of $\tilde{A}^+$ are limit points of $A^+$, $T = \text{id}$ on $A^+$. In particular this implies that

$$
\chi_{\tilde{A}^+}\rho_1 = T_#(\chi_{\tilde{A}^+}\rho_1) = \chi_{T(\tilde{A}^+)T_#\rho_1} = \chi_{\tilde{A}^+}\rho_0,
$$

i.e. $\rho_0 = \rho_1$ on $\tilde{A}^+$. Now if $x \in \tilde{A}^+ \setminus \{a_0, \ldots, a_{N+1}\}$, we may find $\delta > 0$ such that $\rho_0$ is constant on $[x - \delta, x + \delta]$ and $[x - \delta, x + \delta] \cap A^- = \emptyset$, so that $\rho_1$ is nondecreasing on $[x - \delta, x + \delta]$. Define then

$$
x_1 := \inf \tilde{A}^+ \cap [x - \delta, x + \delta], \quad x_2 := \sup \tilde{A}^+ \cap [x - \delta, x + \delta],
$$

since both $x_1$ and $x_2$ lie in $\tilde{A}^+$ and $D\rho_1 = \mu^+ \geq \tilde{\mu}^+$ on $[x - \delta, x + \delta]$ we have

$$
\rho_1(x_2) - \rho_1(x_1) = \rho_0(x_2) - \rho_0(x_1) = 0 \geq \tilde{\mu}^+([x_1, x_2]) = \tilde{\mu}^+([x - \delta, x + \delta])
$$

which contradicts $x \in \tilde{A}^+$. This proves that $\mu^+$ (and $\mu^-$ likewise) are purely atomic (i.e. $\rho_1$ is a jump function in the terminology of [1]):

$$
D\rho_1 = \sum_{x \in J^+} \mu^+ (\{x\}) \delta_x - \sum_{x \in J^-} \mu^- (\{x\}) \delta_x.
$$

**Step 3: the jump sets $J^+$ and $J^-$ are finite.** Recall from the previous step that $A^+ = \overline{J^+}$ and $A^- = \overline{J^-}$ are disjoint sets. In particular, there cannot be points which are both limit points of $J^+$ and $J^-$. We argue by contradiction that $J^+$ is a finite set (a similar argument can be applied for $J^-$). Suppose that $J^+$ is not finite so that for some $x \in J^+$, every neighbourhood of $x$ contains an element of $J^+$. Then, there exists $x_1 \in J^+$ with $x_1 \neq x$ ($x_1 > x$ say) such that $[x, x_1] \cap J^- = \emptyset$ (which implies that $F_1$ is convex on $[x, x_1]$). If $x_2 \in (x, x_1) \cap J^+$, then we know from the previous step that $T(x_2) \geq x_2$ and there exist $c_1 \in (x, x_2)$ and $c_2 \in (x_2, x_1)$ which are fixed points of $T$. 

20
We then have
\[ F_1(x_2) - F_1(c_1) = F_0(T(x_2)) - F_0(c_1) \geq F_0(x_2) - F_0(c_1) \]
and similarly
\[ F_1(c_2) - F_1(x_2) = F_0(c_2) - F_0(T(x_2)) \leq F_0(c_2) - F_0(x_2) \]
but since \( \rho_1 \) has an upward jump at \( x_2 \) we have
\[ \frac{F_1(x_2) - F_1(c_1)}{x_2 - c_1} < \frac{F_1(c_2) - F_1(x_2)}{c_2 - x_2} \]
hence
\[ \frac{F_0(x_2) - F_0(c_1)}{x_2 - c_1} < \frac{F_0(c_2) - F_0(c_1)}{c_2 - x_2} \]
implying that \( \rho_0 \) has a discontinuity point in \([c_1, c_2]\) hence in \([x, x_1]\), since there are only finitely many such points this shows that \( J^+ \) is finite.

**Step 4: \( \rho_1 \) has no more than \( N \) jumps.** We know from the previous steps that \( \rho_1 \) can be written as
\[ \rho_1 = \sum_{k=0}^{K} \beta_k \chi_{(b_k, b_{k+1})}, \ b_0 = a < b_1 < \cdots < b_K < b_{K+1} = b, \beta_k \neq \beta_{k+1} \]
If \( \beta_{k+1} > \beta_k \) arguing exactly as in the previous step, we find two fixed-points of \( T, c_k \in (b_k, b_{k+1}) \) and \( c_{k+1} \in (b_{k+1}, b_{k+2}) \) such that \( \rho_0 \) has a discontinuity in \((c_k, c_{k+1})\), the case of a downward jump \( \beta_k > \beta_{k+1} \) can be treated similarly (using \( T(b_{k+1}) \leq b_{k+1} \) in this case). This shows that \( \rho_0 \) has at least \( K \) jumps so that \( N \geq K \).

\[ \Box \]

### 7 Convergence of the TV-JKO scheme in dimension one

We are now interested in the convergence of the TV-JKO scheme to a solution of the fourth-order nonlinear equation (1.2) in dimension 1, as the time step \( \tau \) goes to 0. Throughout this section, we assume that \( \Omega = (0, 1) \) and that the initial condition \( \rho_0 \) satisfies
\[ \rho_0 \in \mathcal{P}_{ac}((0, 1)) \cap BV((0, 1)), \ \rho_0 \geq \alpha > 0 \ a.e. \ on \ (0, 1). \quad (7.1) \]
We fix a time horizon $T$, and for small $\tau > 0$, define the sequence $\rho^\tau_k$ by
\[
\rho^\tau_0 = \rho_0, \quad \rho^\tau_{k+1} \in \text{argmin}\left\{ \frac{1}{2\tau} W^2_2(\rho^\tau_k, \rho) + J(\rho), \quad \rho \in \text{BV} \cap \mathcal{P}_{ac}((0,1)) \right\} \tag{7.2}
\]
for $k = 0, \ldots N_\tau$ with $N_\tau := \left\lfloor \frac{T}{\tau} \right\rfloor$. Thanks to Proposition 3.4, (7.1) ensures that the JKO-iterates $\rho^\tau_k$ defined by (7.2) also remain bounded from below by $\alpha$. We also extend this discrete sequence by piecewise constant interpolation i.e.
\[
\rho^\tau(t,x) = \rho^\tau_{k+1}(x), \quad t \in (k\tau, (k+1)\tau], \quad k = 0, \ldots N_\tau, \quad x \in (0,1). \tag{7.3}
\]
We shall see that $\rho^\tau$ converges to a solution $\rho$ of
\[
\partial_t \rho + \left( \rho \left( \frac{\rho_x}{|\rho_x|} \right) \right)_x = 0, \quad (t,x) \in (0,T) \times (0,1), \quad \rho|_{t=0} = \rho_0, \tag{7.4}
\]
with the no-flux boundary condition
\[
\rho \left( \frac{\rho_x}{|\rho_x|} \right)_x = 0, \quad \text{on} \quad (0,T) \times \{0,1\}. \tag{7.5}
\]
Since $\rho$ is no more than BV in $x$, one has to be slightly cautious in the meaning of $\frac{\rho_x}{|\rho_x|}$ which be conveniently done by interpreting this term as the negative of a suitable $z$ in the subdifferential of $J$ (in the $L^2$ sense for instance):
\[
z \in H^1_0((0,1)), \quad \|z\|_{L^\infty} \leq 1 \quad \text{and} \quad J(\rho) = \int_0^1 z_x \rho. \tag{7.6}
\]
This leads to the following definition

**Definition 7.1.** A weak solution of (7.4)-(7.1) is a $\rho \in L^\infty((0,T), \text{BV}((0,1))) \cap C^0((0,T), (\mathcal{P}, W_2))$ such that there exists $z \in L^\infty((0,T) \times (0,1)) \cap L^2((0,T), H^2 \cap H^1_0((0,1)))$ with
\[
\|z(t,.)\|_{L^\infty} \leq 1 \quad \text{and} \quad J(\rho(t, .)) = \int_0^1 z_x(t,x) \rho(x) \, dx, \quad \text{for a.e. } t \in (0,T), \tag{7.7}
\]
and $\rho$ is a weak solution of
\[
\partial_t \rho - (\rho z_{xx})_x = 0, \quad \rho|_{t=0} = \rho_0, \quad \rho z_{xx} = 0 \quad \text{on} \quad (0,T) \times \{0,1\}. \tag{7.8}
\]
i.e. for every $u \in C^1_0([0,T] \times [0,1])$
\[
\int_0^T \int_0^1 (\partial_t u \rho - (\rho z_{xx})u_x) \, dx \, dt = - \int_0^1 u(0,x) \rho_0(x) \, dx.
\]
We then have

**Theorem 7.2.** If \( \rho_0 \) satisfies (7.1), there exists a vanishing sequence of time steps \( \tau_n \to 0 \) such that the sequence \( \rho^{\tau_n} \) constructed by (7.2)-(7.3) converges strongly in \( L^p((0,T) \times (0,1)) \) for any \( p \in [1, +\infty) \) and in \( C^0((0,T), \mathcal{P}([0,1]), W_2) \) to \( \rho \in L^\infty((0,T), \text{BV}((0,1))) \cap C^0((0,T), (\mathcal{P}([0,1]), W_2)) \), a weak solution of (7.4)-(7.1).

**Proof.** First, \( \rho_0 \) being BV it is bounded on \( (0,1) \) which gives uniform bounds on \( \rho^{\tau_n} \) thanks to Theorem 3.2, moreover we know from (7.1) and Proposition 3.4 that we also have a uniform bound from below

\[
M := \|\rho_0\|_{L^\infty} \geq \rho^\tau(t,x) \geq \alpha, \ t \in [0,T], \ \text{a.e.} \ x \in [0,1]. \tag{7.9}
\]

Moreover by construction of the TV-JKO scheme (7.2), one has

\[
\frac{1}{2\tau} \sum_{k=0}^N W_2^2(\rho_k^\tau, \rho_{k+1}^\tau) \leq J(\rho_0), \quad \sup_{t \in [0,T]} J(\rho^\tau(t,.)) \leq J(\rho_0) \tag{7.10}
\]

By using an Aubin-Lions type compactness Theorem of Savaré and Rossi (Theorem 2 in [26]), the fact that the imbedding of \( \text{BV}((0,1)) \) into \( L^p((0,T) \times (0,1)) \) is compact for every \( p \in [1, +\infty) \) as well as a refinement of Arzèla-Ascoli Theorem (Proposition 3.3.1 in [2]), one obtains (see section 4 of [13] or section 5 of [8] for details) that, up to taking suitable sequence of vanishing times steps \( \tau_n \to 0 \), we may assume that

\[
\rho^\tau \to \rho \ \text{a.e. in} \ (0,T) \times (0,1) \ \text{and in} \ L^p((0,T) \times (0,1)), \forall p \in [1, +\infty) \tag{7.11}
\]

and

\[
\sup_{t \in [0,T]} W_2(\rho^\tau(t,.), \rho(t,.)) \to 0 \ \text{as} \ \tau \to 0, \tag{7.12}
\]

for some limit curve \( \rho \in C^0([0,T], (\mathcal{P}([0,1]), W_2)) \cap L^p((0,T) \times (0,1)) \). From (7.9) and (7.10), one also deduces \( \rho \in L^\infty((0,T), \text{BV}((0,1))) \) and from (7.9) \( M \geq \rho \geq \alpha \).

We deduce from the fact that \( \rho_k^\tau \geq \alpha > 0 \) and Theorem 4.4 that for each \( k = 0, \ldots, N \), there exists \( z_k^\tau \in W^{2,\infty}((0,1)) \) such that

\[
\|z_k^\tau\|_{L^\infty} \leq 1, \ z_k^\tau(0) = z_k^\tau(1) = 0, \ J(\rho_k^\tau) = \int_0^1 (z_k^\tau x) \rho_k^\tau, \tag{7.13}
\]

and the optimal (backward) optimal transport \( T_{k+1}^\tau \) from \( \rho_{k+1}^\tau \) to \( \rho_k^\tau \) is related to \( z_{k+1}^\tau \) by

\[
id - T_{k+1}^\tau = -\tau(z_{k+1}^\tau)_{xx}. \tag{7.14}
\]
We extend \( z_k^\tau \) in a piecewise constant way i.e. set
\[
z^\tau(t, x) = z_{k+1}^\tau(x), \quad t \in (k\tau, (k+1)\tau], \quad k = 0, \ldots, N_\tau, \quad x \in (0, 1).
\] (7.15)

We then observe that
\[
W_2^2(\rho_k^\tau, \rho_{k+1}^\tau) = \int_0^1 (x - T_k^\tau(x))^2 \rho_{k+1}^\tau(x) dx
\]
\[
= \tau^2 \int_0^1 (z_{k+1}^\tau)^2 \rho_{k+1}^\tau(x) dx
\]
\[
\geq \alpha \tau^2 \int_0^1 (z_{k+1}^\tau)^2 xx dx
\]

Thanks to (7.10) we thus get an \( L^2((0, T), H^2((0, 1))) \) bound
\[
\| z^\tau \|_{L^2((0, T), H^2((0, 1)))} \leq C.
\] (7.16)

We may therefore assume (up to further suitable extractions) that there is some \( z \in L^\infty((0, T) \times (0, 1)) \cap L^2((0, T), H^2((0, 1))) \) such that \( z^\tau \) converges weakly * in \( L^\infty((0, T) \times (0, 1)) \) and weakly in \( L^2((0, T), H^2((0, 1))) \) to \( z \).

Of course \( \| z \|_{L^\infty} \leq 1 \) and \( z \in L^2((0, T), H_0^1((0, 1)). \) Note also that \( \rho^\tau z_{xx}^\tau \) converges weakly to \( \rho z_{xx} \) in \( L^1((0, T) \times (0, 1)) \).

The limiting equation can now be derived using standard computations (see the proof of Theorem 5.1 of the seminal work [18], or chapter 8 of [28]): Let \( u \in C_c^1((0, T) \times [0, 1)) \) and observe that
\[
\int_0^T \int_0^1 \partial_t u \rho^\tau dx dt = \sum_{k=1}^{N_\tau} \left( \int_0^1 u(k\tau, x)(\rho_k^\tau(x) - \rho_{k+1}^\tau(x)) dx \right) - \int_0^1 u(0, x)\rho_1^\tau(x) dx.
\]
Recalling that \( \rho_k^\tau = T_{k+1}^\tau \rho_{k+1}^\tau \), and applying Taylor’s theorem, we have
\[
\sum_{k=1}^{N_\tau} \left( \int_0^1 u(k\tau, x)(\rho_k^\tau(x) - \rho_{k+1}^\tau(x)) dx \right)
\]
\[
= \sum_{k=1}^{N_\tau} \left( \int_0^1 ((T_{k+1}^\tau - x)u_x(k\tau, x) + \tilde{R}_\tau(x)) \rho_{k+1}^\tau dx \right)
\]
\[
= \sum_{k=1}^{N_\tau} \left( \int_0^1 (\tau(z_{k+1}^\tau xx u_x(k\tau, x) + \tilde{R}_\tau(x)) \rho_{k+1}^\tau dx \right),
\]
where \( |\tilde{R}_\tau(x)| \leq C \| u_{xx}(k\tau, \cdot) \|_{L^\infty} \| T_{k+1}^\tau(x) - x \|^2 \). Note also that for \( t \in (k\tau, (k+1)\tau) \), \( |u_x(k\tau, \cdot) - u_x(t, \cdot)| \leq \tau \| u_{xt}\|_{L^\infty} \). Therefore,
\[
\int_0^T \int_0^1 (\partial_t u \rho^\tau - \rho^\tau z_{xx}^\tau u_x) dx dt = - \int_0^1 u(0, x)\rho_1^\tau(x) dx + R_\tau(u) \quad (7.17)
\]

24
\[ |R_\tau(u)| \leq C \max\{\|u_{xx}\|_{L^\infty}, \|u_{xt}\|_{L^\infty}\} \sum_{k=0}^{N} W_2^2(\rho_k^\tau, \rho_{k+1}^\tau) \leq C\tau. \]  
(7.18)

Passing to the limit \( \tau \) to 0 in (7.17) yields that \( \rho \) is a weak solution to

\[ \partial_t \rho - (\rho z_{xx})_x = 0, \quad \rho_{t=0} = \rho_0, \quad \rho z_{xx} = 0 \text{ on } (0, T) \times \{0, 1\}. \]

It remains to prove that \( J(\rho(t, .)) \geq \int_0^1 z_x(t, x)\rho(x)dx \), for a.e. \( t \in (0, T) \). The inequality \( J(\rho(t, .)) \geq \int_0^1 z_x(t, x)\rho(x)dx \) is obvious since \( z(t, \cdot) \in H_0^1((0, 1)) \) and \( \|z(t, .)\|_{L^\infty} \leq 1 \). To prove the converse inequality, we use Fatou’s Lemma, the lower semi-continuity of \( J \), (7.13) and the weak-convergence in \( L^1((0, T) \times (0, 1)) \) of \( z^\tau_x\rho^\tau \) to \( z_x\rho \):

\[
\begin{align*}
\int_0^T J(\rho(t, .))dt &\leq \int_0^1 \liminf_{\tau} J(\rho^\tau(t, .))dt \\
&\leq \liminf_{\tau} \int_0^1 J(\rho^\tau(t, .))dt \\
&= \liminf_{\tau} \int_0^T \int_0^1 z^\tau_x(t, x)\rho^\tau(t, x)dxdt \\
&= \int_0^T \int_0^1 z_x(t, x)\rho(t, x)dxdt
\end{align*}
\]

which concludes the proof.

Acknowledgements: The authors wish to thank Vincent Duval and Gabriel Peyrê for suggesting the TV-Wasserstein problem to them as well as for fruitful discussions. They also thank Maxime Laborde and Filippo Santambrogio for helpful remarks in particular regarding the maximum principle.
