Abstract

In this work we propose and analyze a novel Hybrid High-Order discretization of a class of (linear and) nonlinear elasticity models in the small deformation regime which are of common use in solid mechanics. The proposed method is valid in two and three space dimensions, it supports general meshes including polyhedral elements and nonmatching interfaces, enables arbitrary approximation order, and the resolution cost can be reduced by statically condensing a large subset of the unknowns for linearized versions of the problem. Additionally, the method satisfies a local principle of virtual work inside each mesh element, with interface tractions that obey the law of action and reaction. A complete analysis covering very general stress-strain laws is carried out, and optimal error estimates are proved. Extensive numerical validation on model test problems is also provided on two types of nonlinear models.

1 Introduction

In this work we develop and analyze a novel Hybrid High-Order (HHO) method for a class of (linear and) nonlinear elasticity problems in the small deformation regime.

Let $\Omega \subset \mathbb{R}^d$, $d \in \{2, 3\}$, denote a bounded connected open polyhedral domain with Lipschitz boundary $\Gamma := \partial \Omega$ and outward normal $n$. We consider a body that occupies the region $\Omega$ and is subjected to a volumetric force field $f \in L^2(\Omega; \mathbb{R}^d)$. For the sake of simplicity, we assume the body fixed on $\Gamma$ (extensions to other standard boundary conditions are possible). The nonlinear elasticity problem consists in finding a vector-valued displacement field $u : \Omega \to \mathbb{R}^d$ solution of

$$
-\nabla \cdot \sigma(\cdot, \nabla u) = f \quad \text{in } \Omega, $$

$$
u = 0 \quad \text{on } \Gamma,
$$

where $\nabla \cdot$ denotes the symmetric gradient. The stress-strain law $\sigma : \Omega \times \mathbb{R}^{d \times d} \to \mathbb{R}^{d \times d}_{\text{sym}}$ is assumed to satisfy regularity requirements closely inspired by \cite{27}, including conditions on its growth, coercivity, and monotonicity; cf. Assumption 1 below for a precise statement. Problem (1) is relevant, e.g., in modeling the mechanical behavior of soft materials \cite{45} and metal alloys \cite{41}. Examples of stress-strain laws of common use in the engineering practice are collected in Section 2.

The HHO discretization studied in this work is inspired by recent works on linear elasticity \cite{20} (where HHO methods where originally introduced) and Leray–Lions operators \cite{15,16}. It hinges on degrees of freedom (DOFs) that are discontinuous polynomials of degree $k \geq 1$ on the mesh and on the mesh skeleton. Based on these DOFs, we reconstruct discrete counterparts of the symmetric gradient and of the displacement by solving local linear problems inside each mesh element. These reconstruction...
operators are used to formulate a local contribution composed of two terms: a consistency term inspired by the weak formulation of problem (1) with $\nabla_s$ replaced by its discrete counterpart, and a stabilization term penalizing cleverly designed face-based residuals. The resulting method has several advantageous features: (i) it is valid in arbitrary space dimension; (ii) it supports arbitrary polynomial orders $\geq 1$ on fairly general meshes including, e.g., polyhedral elements and nonmatching interfaces; (iii) it satisfies inside each mesh element a local principle of virtual work with numerical tractions that obey the law of action and reaction; (iv) it can be efficiently implemented thanks to the possibility of statically condensing a large subset of the unknowns for linearized versions of the problem (encountered, e.g., when solving the corresponding system of nonlinear algebraic equations by the Newton method). For a numerical comparison between HHO methods and standard conforming finite element methods in the context of scalar diffusion problems see [21]. Additionally, as shown by the numerical tests of Section 6, the method is robust with respect to strong nonlinearities.

In the context of structural mechanics, discretization methods supporting polyhedral meshes and nonconforming interfaces can be useful for several reasons including, e.g., the use of hanging nodes for contact [7, 48] and interface elasticity [32] problems, the simplicity in mesh refinement [43] and coarsening [3] for adaptivity, and the greater robustness to mesh distortion [12] and fracture [36]. The use of high-order methods, on the other hand, can classically accelerate the convergence in the presence of regular exact solutions or when combined with local mesh refinement. Over the last few years, several discretization schemes supporting polyhedral meshes and/or high-order have been proposed for the linear version of problem (1): a non-exhaustive list includes [4, 20, 22, 23, 42, 46, 47]. For the nonlinear version, the literature is more scarce. Conforming approximations on standard meshes have been considered in [30, 31], where the convergence analysis is carried out assuming regularity for the exact displacement field $\mathbf{u}$ and the constraint tensor $\sigma(\cdot, \nabla_s \mathbf{u})$ beyond the minimal regularity required by the weak formulation. Discontinuous Galerkin methods on standard meshes have been considered in [40], where convergence is proved for $d = 2$ assuming $\mathbf{u} \in H^{m+1}(\Omega; \mathbb{R}^2)$ for some $m > 2$, and in [6], where convergence to minimal regularity solutions is proved for stress-strain functions similar to [5]. General meshes are considered, on the other hand, in [5] and [11], where the authors propose a low-order Virtual Element method, whose convergence analysis is carried out for nonlinear elastic problems in the small deformation regime (more general problems are considered numerically). In [5], an energy-norm convergence estimate in $h$ (with $h$ denoting, as usual, the meshsize) is proved when $\mathbf{u} \in H^2(\Omega; \mathbb{R}^d)$ under the assumption that the function $\tau \mapsto \sigma(\cdot, \tau)$ is piecewise $C^1$ with positive definite and bounded differential inside each element. A closer look at the proof reveals that properties essentially analogous to the ones considered in Assumption 12 below are in fact sufficient for the analysis, while $C^1$-regularity is used for the evaluation of the stability constant. Convergence to solutions that exhibit only the minimal regularity required by the weak formulation and for stress-strain functions as in Assumption 1 is proved in [27] for Gradient Schemes [26]. In this case, convergence rates are only proved for the linear case. We note, in passing, that the HHO method studied here fails to enter the Gradient Scheme framework essentially because the stabilization term is not embedded into the discrete symmetric gradient operator; see [18].

We carry out a complete analysis for the proposed HHO discretization of problem (1). Existence of a discrete solution is proved in Theorem 7, where we also identify a strict monotonicity assumption on the stress-strain law which ensures uniqueness. Convergence to minimal regularity solutions $\mathbf{u} \in H^1_0(\Omega; \mathbb{R}^d)$ is proved in Theorem 9 using a compactness argument inspired by [15, 27]. More precisely, we prove for monotone stress-strain laws that (i) the discrete displacement field strongly converges (up to a subsequence) to $\mathbf{u}$ in $L^q(\Omega; \mathbb{R}^d)$ with $1 \leq q < +\infty$ if $d = 2$ and $1 \leq q < 6$ if $d = 3$; (ii) the discrete strain tensor weakly converges (up to a subsequence) to $\nabla_s \mathbf{u}$ in $L^2(\Omega, \mathbb{R}^{d \times d})$. Notice that our results are slightly stronger than [27, Theorem 3.5] (cf. also Remark 3.6 therein) because the HHO discretization is compact as proved in Lemma 18. If, additionally, strict monotonicity holds for $\sigma$, the strain tensor strongly converges and convergence extends to the whole sequence. An optimal energy-norm error estimate in $h^{k+1}$ is then proved in Theorem 14 under the additional conditions of Lipschitz continuity and strong monotonicity on the stress-strain law; cf. Assumption 12. The performance of the method is investigated in Section 6 on a complete panel of model problems using stress-strain laws corresponding to real materials.
The rest of the paper is organized as follows. In Section 2 we formulate the assumptions on the stress-strain function $\sigma$, provide several examples of models relevant in the engineering practice, and write the weak formulation of problem (1). In Section 3 we introduce the notation for the mesh and recall a few known results. In Section 4 we discuss the choice of DOFs, formulate the local reconstructions, and state the discrete problem along with the main results, collected in Theorems 7, 9, and 14. In Section 5 we show that the IHO method satisfies on each mesh element a discrete counterpart of the principle of virtual work, and that interface tractions obey the law of action and reaction. Section 6 contains numerical tests, while the proofs of the main results are given in Section 7. Finally, Appendix A contains the proofs of intermediate technical results. This structure allows different levels of reading. In particular, readers mainly interested in the numerical recipe and results may focus primarily on the material of Sections 2–6.

\section{Setting and examples}

For the stress-strain function, we make the following

**Assumption 1** (Stress-strain function I). The stress-strain function $\sigma : \Omega \times \mathbb{R}_{\text{sym}}^{d \times d} \to \mathbb{R}_{\text{sym}}^{d \times d}$ is a Carathéodory function, namely

- $\sigma(x,\cdot)$ is continuous on $\mathbb{R}_{\text{sym}}^{d \times d}$ for a.e. $x \in \Omega$, \hspace{1cm} (2a)
- $\sigma(\cdot,\tau)$ is measurable on $\Omega$ for all $\tau \in \mathbb{R}_{\text{sym}}^{d \times d}$, \hspace{1cm} (2b)

and it holds $\sigma(\cdot,0) \in L^2(\Omega;\mathbb{R}_{\text{sym}}^{d \times d})$. Moreover, there exist real numbers $\sigma_1, \sigma_2 \in (0,\infty)$ such that, for a.e. $x \in \Omega$, and all $\tau, \eta \in \mathbb{R}_{\text{sym}}^{d \times d}$, the following conditions hold:
- $|\sigma(x,\tau) - \sigma(x,0)|_{d \times d} \leq \mathcal{P} \|	au\|_{d \times d}$, \hspace{1cm} (growth) (2c)
- $\sigma(x,\tau) : \tau \geq \mathcal{G} \|	au\|_{d \times d}^2$, \hspace{1cm} (coercivity) (2d)
- $(\sigma(x,\tau) - \sigma(x,\eta)) : (\tau - \eta) \geq 0$, \hspace{1cm} (monotonicity) (2e)

where $\tau : \eta := \sum_{i,j=1}^d \tau_{i,j} \eta_{i,j}$ and $\|	au\|_{d \times d}^2 := \tau : \tau$.

We next discuss a number of meaningful models that satisfy the above assumptions.

**Example 2** (Linear elasticity). The linear elasticity model corresponds to

$$\sigma(\cdot, \nabla x u) = C(\cdot) \nabla x u,$$

where $C$ is a fourth order tensor. Being linear, the previous stress-strain relation clearly satisfies Assumption 1 provided that $C$ is uniformly elliptic. A particular case of the previous stress-strain relation is the usual linear elasticity Cauchy stress tensor

$$\sigma(\nabla x u) = \lambda \text{tr}(\nabla x u) I_d + 2\mu \nabla x u,$$

where $\text{tr}(\tau) := \tau : I_d$ and $\lambda, \mu \in \mathbb{R}$ are Lamé’s parameters.

**Example 3** (Hencky–Mises model). The nonlinear Hencky–Mises model of [31, 38] corresponds to the stress-strain relation

$$\sigma(\nabla x u) = \hat{\lambda} \text{dev}(\nabla x u) \text{tr}(\nabla x u) I_d + 2\hat{\mu} \text{dev}(\nabla x u) \nabla x u,$$

where $\hat{\lambda}$ and $\hat{\mu}$ are the nonlinear Lamé’s scalar functions and $\text{dev} : \mathbb{R}_{\text{sym}}^{d \times d} \to \mathbb{R}$ defined by $\text{dev}(\tau) = \text{tr}(\tau^2) - \frac{1}{3} \text{tr}(\tau)^2$ is the deviatoric operator. Conditions on $\hat{\lambda}$ and $\hat{\mu}$ such that $\sigma$ satisfies Assumption 1 can be found in [2, 5].

**Example 4** (An isotropic damage model). The isotropic damage model of [10] corresponds to the stress-strain relation

$$\sigma(\cdot, \nabla x u) = (1 - D(\nabla x u))C(\cdot) \nabla x u,$$

where $D : \mathbb{R}_{\text{sym}}^{d \times d} \to \mathbb{R}$ is the scalar damage function. If there exists a continuous and bounded function $f : [0, +\infty) \to [0, b]$ for some $0 < a \leq b$, such that $s \in [0, +\infty) \to sf(s)$ is non-decreasing and, for all $\tau \in \mathbb{R}_{\text{sym}}^{d \times d}$, $D(\tau) = 1 - f(|\tau|)$, the damage model constitutive relation satisfies Assumption 1.
In the numerical experiments of Section 6 we will also consider the following model, relevant in engineering applications, which however does not satisfy Assumption 1 in general.

**Example 5** (The second-order elasticity model). The nonlinear second-order isotropic elasticity model of [14, 34, 35] corresponds to the stress-strain relation

\[
\sigma(\nabla_s u) = \lambda \text{tr}(\nabla_s u) I_d + 2\mu \nabla_s u \\
+ B \text{tr}((\nabla_s u)^2) I_d + 2B \text{tr}(\nabla_s u) \nabla_s u + C \text{tr}(\nabla_s u)^2 I_d + A(\nabla_s u)^2,
\]

where \(\lambda\) and \(\mu\) are the standard Lamé’s parameter, and \(A, B, C \in \mathbb{R}\) are the second-order moduli.

**Remark 6** (Energy density functions). Examples 2, 3, and 5, used in numerical tests of Section 6, can be interpreted in the framework of hyperelasticity. Hyperelasticity is a type of constitutive model for ideally elastic materials in which the stress-strain relation derives from a stored energy density function \(\Psi : \mathbb{R}^{d \times d}_{\text{sym}} \to \mathbb{R}\), namely,

\[
\sigma(\tau) := \frac{\partial \Psi(\tau)}{\partial \tau}.
\]

The stored energy density function leading to the linear Cauchy stress tensor (3) is

\[
\Psi_{\text{lin}}(\tau) := \frac{\lambda}{2} \text{tr}(\tau)^2 + \mu \text{tr}(\tau^2),
\]

while, in the Hencky–Mises model (4), it is defined such that

\[
\Psi_{\text{hm}}(\tau) := \frac{\alpha}{2} \text{tr}(\tau)^2 + \Phi(\text{dev}(\tau)).
\]

Here \(\alpha \in (0, +\infty)\), while \(\Phi : [0, +\infty) \to \mathbb{R}\) is a function of class \(C^2\) satisfying, for some positive constants \(C_1, C_2, \text{ and } C_3,\)

\[
C_1 \leq \Phi(\rho) < \alpha, \quad |\rho\Phi''(\rho)| \leq C_2 \quad \text{and} \quad \Phi(\rho) + 2\rho\Phi''(\rho) \geq C_3 \quad \forall \rho \in [0, +\infty).
\]

Deriving the energy density function (8) yields the stress-strain relation (4) with nonlinear Lamé’s functions \(\hat{\mu}(\rho) := \Phi'(\rho)\) and \(\hat{\lambda}(\rho) := \alpha - \Phi'(\rho)\). Taking \(\alpha = \lambda + \mu\) and \(\Phi(\rho) = \mu \rho\) in (8) leads to the linear case. Finally, the second-order elasticity model (6) is obtained by adding third-order terms to the linear stored energy density function defined in (7):

\[
\Psi_{\text{ssd}}(\tau) := \frac{\lambda}{2} \text{tr}(\tau)^2 + \mu \text{tr}(\tau^2) + \frac{C}{3} \text{tr}(\tau^3) + B \text{tr}(\tau) \text{tr}(\tau^2) + \frac{A}{3} \text{tr}(\tau^3).
\]

The weak formulation of problem (1) that will serve as a starting point for the development and analysis of the HHO method reads

\[
\text{Find } u \in H^1_0(\Omega; \mathbb{R}^d) \text{ such that } a(u, v) = \int_\Omega f \cdot v \quad \forall v \in H^1_0(\Omega; \mathbb{R}^d),
\]

where \(H^1_0(\Omega; \mathbb{R}^d)\) is the zero-trace subspace of \(H^1(\Omega; \mathbb{R}^d)\) and the function \(a : H^1_0(\Omega; \mathbb{R}^d) \times H^1_0(\Omega; \mathbb{R}^d) \to \mathbb{R}\) is such that

\[
a(v, w) := \int_\Omega \sigma(x, \nabla_s v(x)) : \nabla_s w(x) dx.
\]

Throughout the rest of the paper, to alleviate the notation, we omit the dependence on the space variable \(x\) and the differential \(dx\) from integrals.

### 3 Notation and basic results

We consider refined sequences of general polytopal meshes as in [26, Definition 7.2] matching the regularity requirements detailed in [24, Definition 3]. The main points are summarized hereafter. Denote by \(\mathcal{H} \subset \mathbb{R}^+\) a countable set of meshsizes having 0 as its unique accumulation point, and let
Throughout the rest of the paper, for $\Omega$, we denote by $\|\cdot\|_X$ the standard norm in $L^2(X;\mathbb{R})$, with the convention that the subscript is omitted whenever $X = \Omega$. The same notation is used for the vector- and tensor-valued spaces $L^2(X;\mathbb{R}^d)$ and $L^2(X;\mathbb{R}^{d\times d})$.

4 The Hybrid High-Order method

In this section we define the space of DOFs and the local reconstructions, and we state the discrete problem along with the main results (whose proof is postponed to Section 7).
4.1 Degrees of freedom

Let a polynomial degree $k \geq 1$ be fixed. The DOFs for the displacement are collected in the space

$$
\mathcal{U}_T^k := \left( \bigtimes_{T \in \mathcal{T}_h} \mathbb{P}^k(T; \mathbb{R}^d) \right) \times \left( \bigtimes_{F \in \mathcal{F}_h} \mathbb{P}^k(F; \mathbb{R}^d) \right),
$$

see Figure 1. Observe that naming $\mathcal{U}_T^k$ the space of DOFs involves a shortcut: the actual DOFs can be chosen in several equivalent ways (polynomial moments, point values, etc.), and the specific choice does not affect the following discussion. Details concerning the actual choice made in the implementation are given in Section 6 below.

For a generic collection of DOFs in $\mathcal{U}_T^k$, we use the classical HHO underlined notation $v_h := ((v_T)_{T \in \mathcal{T}_h}, (v_F)_{F \in \mathcal{F}_h})$. We also denote by $v_h \in \mathbb{P}^k(\mathcal{T}_h; \mathbb{R}^d)$ and $v_{\Gamma,h} \in \mathbb{P}^k(\mathcal{F}_h^b; \mathbb{R}^d)$ (not underlined) the broken polynomial functions such that

$$(v_h)_{T} = v_T \quad \forall T \in \mathcal{T}_h \quad \text{and} \quad (v_{\Gamma,h})_F = v_F \quad \forall F \in \mathcal{F}_h^b.$$ 

The restrictions of $\mathcal{U}_T^k$ and $v_h$ to a mesh element $T$ are denoted by $\mathcal{U}_T^k$ and $v_T = (v_T, (v_F)_{F \in \mathcal{F}_T})$, respectively. The space $\mathcal{U}_T^k$ is equipped with the following discrete strain semi-norm:

$$
\|v_h\|_{\varepsilon,h} := \left( \sum_{T \in \mathcal{T}_h} \|v_h\|_{\varepsilon,T}^2 \right)^{\frac{1}{2}}, \quad \|v_h\|_{\varepsilon,T}^2 := \|\nabla v_T\|_T^2 + \sum_{F \in \mathcal{F}_T} h_F^{-1} \|v_F - v_T\|^2_F. \quad (14)
$$

The DOFs corresponding to a given function $v \in H^1(\Omega; \mathbb{R}^d)$ are obtained by means of the reduction map $I_k^h : H^1(\Omega; \mathbb{R}^d) \to \mathcal{U}_T^k$ such that

$$
I_k^h v := (\pi_T^k v)_{T \in \mathcal{T}_h}, (\pi_F^k v)_{F \in \mathcal{F}_h}, \quad (15)
$$

where we remind the reader that $\pi_T^k$ and $\pi_F^k$ denote the $L^2$-orthogonal projectors on $\mathbb{P}^k(T; \mathbb{R}^d)$ and $\mathbb{P}^k(F; \mathbb{R}^d)$, respectively. For all mesh elements $T \in \mathcal{T}_h$, the local reduction map $I_k^h : H^1(T; \mathbb{R}^d) \to \mathcal{U}_T^k$ is obtained by a restriction of $I_k^h$, and is therefore such that for all $v \in H^1(T; \mathbb{R}^d)$

$$
I_T^k v = (\pi_T^k v, (\pi_F^k v)_{F \in \mathcal{F}_T}). \quad (16)
$$

4.2 Local reconstructions

We introduce symmetric gradient and displacement reconstruction operators devised at the element level that are instrumental in the formulation of the method.

Let a mesh element $T \in \mathcal{T}_h$ be fixed. The local symmetric gradient reconstruction operator

$$
G_{s,T}^k : \mathcal{U}_T^k \to \mathbb{P}^k(T; \mathbb{R}^{d \times d}_{\text{sym}})
$$

Figure 1: Local DOFs for $k = 1$ (left) and $k = 2$ (right). Shaded DOFs can be locally eliminated by static condensation when solving linearized versions of problem (21).
is obtained by solving the following pure traction problem: For a given local collection of DOFs \( \mathbf{v}_T = (v_T, (v_F)_{F \in F_T}) \in U^k_T \), find \( G^{k}_{s,T} \mathbf{v}_T \in \mathbb{P}^k(T; \mathbb{R}^{d \times d}) \) such that, for all \( \tau \in \mathbb{P}^k(T; \mathbb{R}^{d \times d}) \),

\[
\int_T G^{k}_{s,T} \mathbf{v}_T : \tau = - \int_T v_T \cdot (\nabla \cdot \tau) + \sum_{F \in F_T} \int_F v_F \cdot (\tau n_{TF})
\]

\[
= \int_T \nabla_s v_T : \tau + \sum_{F \in F_T} \int_F (v_F - v_T) \cdot (\tau n_{TF}).
\]

(17a)

(17b)

The right-hand side of (17a) is designed to resemble an integration by parts formula where the role of the function represented by the DOFs in \( v_T \) is played by \( v_T \) inside the volumetric integral and by \( (v_F)_{F \in F_T} \) inside boundary integrals. The reformulation (17b), obtained integrating by parts the first term in the right-hand side of (17a), highlights the fact that our method is nonconforming, as the second addend accounts for the difference between \( v_F \) and \( v_T \).

The definition of the symmetric gradient reconstruction is justified observing that, using the definitions (16) of the local reduction map \( L^k_T \) and (12) of the \( L^2 \)-orthogonal projectors \( \pi^k_T \) and \( \pi^k_F \) in (17a), one can prove the following commuting property: For all \( T \in \mathcal{T}_h \) and all \( \mathbf{v} \in H^1(T; \mathbb{R}^d) \),

\[
G^{k}_{s,T} L^k_F \mathbf{v} = \pi^k_T (\nabla_s \mathbf{v}).
\]

(18)

As a result of (18) and (13), \( G^{k}_{s,T} L^k_F \) has optimal approximation properties in \( \mathbb{P}^k(T; \mathbb{R}^{d \times d}) \).

From \( G^{k}_{s,T} \), one can define the local displacement reconstruction operator

\[
r^{k+1}_T : U^k_T \to \mathbb{P}^{k+1}(T; \mathbb{R}^d)
\]

such that, for all \( \mathbf{v}_T \in U^k_T \), \( \nabla_s r^{k+1}_T \mathbf{v}_T \) is the orthogonal projection of \( \nabla_s G^{k}_{s,T} \mathbf{v}_T \) on \( \nabla_s \mathbb{P}^{k+1}(T; \mathbb{R}^d) \subset \mathbb{P}^k(T; \mathbb{R}^d \times \mathbb{R}^d) \) and rigid-body motions are prescribed according to [20, Eq. (15)]. More precisely, we let \( r^{k+1}_T \mathbf{v}_T \) be such that for all \( w \in \mathbb{P}^{k+1}(T; \mathbb{R}^d) \) it holds

\[
\int_T (\nabla_s r^{k+1}_T \mathbf{v}_T - G^{k}_{s,T} \mathbf{v}_T) : \nabla_s w = 0.
\]

and, denoting by \( \nabla_{ss} \) the skew-symmetric part of the gradient operator, we have

\[
\int_T r^{k+1}_T \mathbf{v}_T = \int_T \mathbf{v}_T, \quad \int_T \nabla_{ss} r^{k+1}_T \mathbf{v}_T = \sum_{F \in F_T} \int_F \frac{1}{2} (n_{TF} \otimes v_F - v_F \otimes n_{TF}).
\]

Notice that, for a given \( \mathbf{v}_T \in \mathbb{P}^k_T \), the displacement reconstruction \( r^{k+1}_T \mathbf{v}_T \) is a vector-valued polynomial function one degree higher than the element-based DOFs \( v_T \). It was proved in [20, Lemma 2] that \( r^{k+1}_T \mathbf{v}_T \) has optimal approximation properties in \( \mathbb{P}^{k+1}(T; \mathbb{R}^d) \).

In what follows, we will also need the global counterparts of the discrete gradient and displacement operators \( G^{k}_{s,h} : U^k_h \to \mathbb{P}^k(\mathcal{T}_h; \mathbb{R}^{d \times d}) \) and \( r^{k+1}_h : U^k_h \to \mathbb{P}^{k+1}(\mathcal{T}_h; \mathbb{R}^d) \) defined setting, for all \( \mathbf{v}_h \in U^k_h \)

\[
(G^{k}_{s,h} \mathbf{v}_h)|T = G^{k}_{s,T} \mathbf{v}_T, \quad (r^{k+1}_h \mathbf{v}_h)|T = r^{k+1}_T \mathbf{v}_T.
\]

(19)

4.3 Discrete problem

We define the following subspace of \( U^k_h \) strongly accounting for the homogeneous Dirichlet boundary condition (1b):

\[
U^k_{h,0} := \left\{ \mathbf{v}_h \in U^k_h \mid v_F = 0 \quad \forall F \in F^k_h \right\},
\]

(20)

and we notice that the map \( \| \cdot \|_{e,h} \) defined by (14) is a norm on \( U^k_{h,0} \). The HHO approximation of problem (11) reads:

Find \( \mathbf{u}_h \in U^k_{h,0} \) such that \( a_h(\mathbf{u}_h, \mathbf{v}_h) := A_h(\mathbf{u}_h, \mathbf{v}_h) + s_h(\mathbf{u}_h, \mathbf{v}_h) = \int_\Omega f : v_h \quad \forall \mathbf{v}_h \in U^k_{h,0} \).

(21)
where the consistency contribution \( A_h : \mathbf{U}_h \times \mathbf{U}_h \to \mathbb{R} \) and the stability contribution \( s_h : \mathbf{U}_h \times \mathbf{U}_h \to \mathbb{R} \) are respectively defined setting

\[
A_h(\mathbf{u}_h, \mathbf{v}_h) := \int_{\Omega} \sigma (\cdot, \mathbf{G}_{s,h}^\tau \mathbf{u}_h) : \mathbf{G}_{s,h}^\tau \mathbf{v}_h, \tag{22}
\]

\[
s_h(\mathbf{u}_h, \mathbf{v}_h) := \sum_{T \in \mathcal{T}_h} s_T(\mathbf{u}_T, \mathbf{v}_T), \quad \text{with} \quad s_T(\mathbf{u}_T, \mathbf{v}_T) := \sum_{F \in \mathcal{F}_T} \frac{\gamma}{h_F} \int_F \mathbf{\Delta}^k_{TF} \mathbf{u}_T : \mathbf{\Delta}^k_{TF} \mathbf{v}_T. \tag{23}
\]

The scaling parameter \( \gamma > 0 \) in (23) can depend on \( \pi \) and \( \rho \) but is independent of the meshsize \( h \).

In the numerical tests of Section 6 we take \( \gamma = 2\mu \) for the linear (3) and second-order (6) models and \( \gamma = 2\overline{\mu}(0) \) for the Hencky–Mises model (4). In \( s_T \), we penalize in a least-square sense the face-based residual \( \mathbf{\Delta}^k_{TF} : \mathbf{U}_h^k \to \mathbb{P}^k(F; \mathbb{R}^d) \) such that, for all \( T \in \mathcal{T}_h \), all \( \mathbf{v}_T \in \mathbf{U}_h^k \), and all \( F \in \mathcal{F}_T \),

\[
\mathbf{\Delta}^k_{TF} \mathbf{v}_T := \pi^k_F (r^k_F \mathbf{u}_T - \mathbf{v}_F) - \pi^k_F (r^{k+1}_F \mathbf{u}_T - \mathbf{v}_F). \tag{24}
\]

This particular choice ensures that \( \mathbf{\Delta}^k_{TF} \) vanishes whenever its argument is of the form \( I^k_F \mathbf{w} \) with \( \mathbf{w} \in \mathbb{P}^{k+1}(T; \mathbb{R}^d) \), a crucial property to obtain an energy-norm error estimate in \( h^{k+1} \); cf. Theorem 14. Additionally, \( s_h \) is stabilizing in the sense that the following uniform norm equivalence holds (the proof is a straightforward modification of [20, Lemma 4]; cf. also Corollary 6 therein): There exists a real number \( \eta > 0 \) independent of \( h \) such that, for all \( \mathbf{v}_h \in \mathbf{U}_{h,0}^k \),

\[
\eta^{-1} \| \mathbf{v}_h \|_{1,h}^2 \leq \| \mathbf{G}_{s,h}^\tau \mathbf{v}_h \|^2 + s_h(\mathbf{v}_h, \mathbf{v}_h) \leq \eta \| \mathbf{v}_h \|_{1,h}^2. \tag{25}
\]

By (2d), this implies the coercivity of \( a_h \).

### 4.4 Main Results

In this section we collect the main results of this paper. The proofs are postponed to Section 7. We start by discussing existence and uniqueness of the discrete solution.

**Theorem 7** (Existence and uniqueness of a discrete solution). Let Assumption 1 hold and let \((\mathcal{T}_h)_{h \in \mathcal{H}}\) be a regular mesh sequence. Then, for all \( h \in \mathcal{H} \), there exists at least one solution \( \mathbf{u}_h \in \mathbf{U}_{h,0}^k \) to problem (21). Additionally, if the stress-strain function \( \sigma \) is strictly monotone (i.e., if the inequality in (26) is strict for \( \tau \neq \eta \)), the solution is unique.

**Proof.** See Section 7.1. \( \square \)

**Remark 8** (Strict monotonicity of the stress-strain function). The strict monotonicity assumption is fulfilled, e.g., by the Hencky–Mises model (4) and by the damage model (5) when \( D(\tau) = 1 - f(|\tau|) \), with \( f \) continuous, bounded, and such that \([0, +\infty) \ni s \mapsto sf(s)\) is strictly increasing. We observe, in passing, that the strict monotonicity is weaker than the strong monotonicity (27b) used in Theorem 14 to prove error estimates.

We then consider the convergence to solutions that only exhibit the minimal regularity required by the variational formulation (11).

**Theorem 9** (Convergence). Let Assumption 1 hold, let \( k \geq 1 \), and let \((\mathcal{T}_h)_{h \in \mathcal{H}}\) be a regular mesh sequence. Further assume the existence of a real number \( C_K > 0 \) independent of \( h \) but possibly depending on \( \Omega, \varrho, \) and on \( k \) such that, for all \( \mathbf{v}_h \in \mathbf{U}_{h,0}^k \),

\[
\| \mathbf{v}_h \| + \| \nabla_h \mathbf{v}_h \| \leq C_K \| \mathbf{v}_h \|_{1,h}, \tag{26}
\]

where \( \nabla_h \) denotes the broken gradient on \( H^1(\mathcal{T}_h; \mathbb{R}^d) \). For all \( h \in \mathcal{H} \), let \( \mathbf{u}_h \in \mathbf{U}_{h,0}^k \) be a solution to the discrete problem (21) on \( \mathcal{T}_h \). Then, for all \( q \) such that \( 1 \leq q < +\infty \) if \( d = 2 \) or \( 1 \leq q < 6 \) if \( d = 3 \), as \( h \to 0 \) it holds, up to a subsequence,

- \( \mathbf{u}_h \to \mathbf{u} \) strongly in \( L^q(\Omega; \mathbb{R}^d) \),
- \( \mathbf{G}_{s,h}^\tau \mathbf{u}_h \to \nabla s \mathbf{u} \) weakly in \( L^2(\Omega; \mathbb{R}^{d \times d}) \),
where \( u \in H^1_\varepsilon(\Omega; \mathbb{R}^d) \) solves the weak formulation (11). Moreover, if we assume strict monotonicity for \( \sigma \) (i.e., the inequality in (26) is strict for \( \tau \neq \eta \)), it holds that

\[
\begin{align*}
&\bullet \quad G_{k,h}^{s}u_h \to \nabla_s u \quad \text{strongly in} \quad L^2(\Omega; \mathbb{R}^{d \times d}).
\end{align*}
\]

Finally, if the solution to (11) is unique, convergence extends to the whole sequence.

**Proof.** See Section 7.2.

**Remark 10** (Existence of a solution to the continuous problem). Notice that a side result of the existence of discrete solutions proved in Theorem 7 together with the convergence results of Theorem 9 is the existence of a solution to the weak formulation (11).

**Remark 11** (Discrete Korn inequality). In Proposition 20 we give a proof of the discrete Korn inequality (26) based on the results of [8], which require further assumptions on the mesh. While we have the feeling that these assumptions could probably be relaxed, we postpone this topic to a future work. Notice that inequality (26) is not required to prove the error estimate of Theorem 14.

In order to prove error estimates, we stipulate the following additional assumptions on the stress-strain function \( \sigma \).

**Assumption 12** (Stress-strain relation II). There exist real numbers \( \sigma^\alpha, \sigma_\ast \in (0, +\infty) \) such that, for a.e. \( x \in \Omega \), and all \( \tau, \eta \in \mathbb{R}^{d \times d} \):

\[
\begin{align*}
&\|\sigma(x, \tau) - \sigma(x, \eta)\|_{d \times d} \leq \sigma^\alpha \|\tau - \eta\|_{d \times d}, \quad \text{(Lipschitz continuity)} 
&\left(\sigma(x, \tau) - \sigma(x, \eta)\right) : (\tau - \eta) \geq \sigma_\ast \|\tau - \eta\|_{d \times d}^2, \quad \text{(strong monotonicity)}
\end{align*}
\]

**Remark 13** (Lipschitz continuity and strong monotonicity). It has been proved in [2, Lemma 4.1] that, under the assumptions (9), the stress-strain tensor function for the Hencky–Mises model is strongly monotone and Lipschitz-continuous, namely Assumption 12 holds. Also the isotropic damage model satisfies Assumption 12 if the damage function in (5) is, for instance, such that \( D(|\tau|) = 1 - (1 + |\tau|)^{-\frac{1}{2}} \).

**Theorem 14** (Error estimate). Let Assumptions 1 and 12 hold, and let \((\mathcal{T}_h)_{h \in \mathcal{H}}\) be a regular mesh sequence. Let \( u \) be the unique solution to (1). Let a polynomial degree \( k \geq 1 \) be fixed, and, for all \( h \in \mathcal{H} \), let \( u_h \) be the unique solution to (21) on the mesh \( \mathcal{T}_h \). Then, under the additional regularity \( u \in H^{k+2}(\mathcal{T}_h; \mathbb{R}^d) \) and \( \sigma(\cdot, \nabla_s u) \in H^{k+1}(\mathcal{T}_h; \mathbb{R}^{d \times d}) \), it holds

\[
\|\nabla_s u - G_{k,h}^{s}u_h\| + s_h(u_h, u_h)^{1/2} \leq C k^{b+1} \left(\|u\|_{H^{k+2}(\mathcal{T}_h; \mathbb{R}^d)} + \|\sigma(\cdot, \nabla_s u)\|_{H^{k+1}(\mathcal{T}_h; \mathbb{R}^{d \times d})}\right),
\]

where \( C \) is a positive constant depending only on \( \Omega, k, \) the mesh regularity parameter \( \varrho \), the real numbers \( \sigma, \sigma_\ast, \sigma^\alpha, \sigma_\ast \) appearing in (2) and in (27), and an upper bound of \( \|f\| \).

**Proof.** See Section 7.3.

**Remark 15** (Locking-free error estimate). The proposed scheme, although different from the one of [20], is robust in the quasi-incompressible limit. The reason is that, as a result of the commuting property (18), we have \( \pi_f^{y}(\nabla \cdot v) = \text{tr}(G_{k+1}^{y}v) \). Thus, considering, e.g., the linear elasticity stress-strain relation (3), we can proceed as in [20, Theorem 8] in order to prove that, when \( u \in H^{k+2}(\mathcal{T}_h; \mathbb{R}^d) \) and \( \nabla u \in H^{k+1}(\mathcal{T}_h; \mathbb{R}^d) \), and choosing \( \gamma = 2\mu \), it holds

\[
(2\mu)^{1/2} \|\nabla_s u - G_{k,h}^{s}u_h\| \leq C k^{b+1} \left(2\mu\|u\|_{H^{k+2}(\mathcal{T}_h; \mathbb{R}^d)} + \lambda\|\nabla u\|_{H^{k+1}(\mathcal{T}_h; \mathbb{R}^d)}\right),
\]

with real number \( C > 0 \) is independent of \( h, \mu \) and \( \lambda \). The previous bound leads to a locking-free estimate; see [20, Remark 9]. Note that the locking-free nature of polyhedral element methods has also been observed in [46] for the Weak Galerkin method and in [4] for the Virtual Element method.
5 Local principle of virtual work and law of action and reaction

We show in this section that the solution of the discrete problem (21) satisfies inside each element a local principle of virtual work with numerical tractions that obey the law of action and reaction. This property is important from both the mathematical and engineering points of view, and it can simplify the derivation of a posteriori error estimators based on equilibrated tractions; see, e.g., [1, 39]. It is worth emphasizing that local equilibrium properties on the primal mesh are a distinguishing feature of hybrid (face-based) methods: the derivation of similar properties for vertex-based methods usually requires to perform reconstructions on a dual mesh.

Define, for all $T \in \mathcal{T}_h$, the space

$$D^k_{\mathcal{T}} := \bigoplus_{F \in \mathcal{F}_T} \mathbb{P}^k(F; \mathbb{R}^d),$$

as well as the boundary difference operator $\delta^k_{\mathcal{T}} : U^k_T \rightarrow D^k_{\mathcal{T}}$ such that, for all $v_T \in U^k_T$,

$$\delta^k_{\mathcal{T}} v_T = (\delta_F v_T)_{F \in \mathcal{F}_T} := (v_F - v_T)_{F \in \mathcal{F}_T}.$$  

The following proposition shows that the stabilization can be reformulated in terms of boundary differences.

**Proposition 16 (Reformulation of the local stabilization bilinear form).** For all mesh element $T \in \mathcal{T}_h$, the local stabilization bilinear form $s_T$ defined by (23) satisfies, for all $u_T, v_T \in U^k_T$,

$$s_T(u_T, v_T) = s_T((0, \delta^k_{\mathcal{T}} u_T), (0, \delta^k_{\mathcal{T}} v_T)).$$

**(Proof.** Let a mesh element $T \in \mathcal{T}_h$ be fixed. Using the fact that $r_T^{k+1} L_T^k v_T = v_T$ for all $v_T \in \mathbb{P}^k(T; \mathbb{R}^d)$ (this because $r_T^{k+1} L_T^k$ is a projector on $\mathbb{P}^{k+1}(T; \mathbb{R}^d)$, cf. [20, Eq. (20)]) together with the linearity of $r_T^{k+1}$, it is inferred that, for all $F \in \mathcal{F}_T$, the face-based residual defined by (24) satisfies

$$\Delta^k_{TF} := \pi_T^F(r_T^{k+1} (0, \delta^k_{\mathcal{T}} v_T) - \delta^k_{TF} v_T) - \pi_T^F r_T^{k+1} (0, \delta^k_{TF} v_T) = \Delta^k_{TF} (0, \delta^k_{TF} v_T)$$

for all $v_T \in U^k_T$. Plugging this expression into (23) yields the assertion. \)

**Define now the boundary residual operator $R^k_{\mathcal{T}} : U^k_T \rightarrow D^k_{\mathcal{T}}$ such that, for all $v_T \in U^k_T$, $R^k_{TF} v_T := (R^k_{TF} v_T)_{F \in \mathcal{F}_T}$ satisfies**

$$- \sum_{F \in \mathcal{F}_T} \int_F R^k_{TF} v_T \alpha_F = s_T((0, \delta^k_{\mathcal{T}} v_T), (0, \alpha_{\mathcal{T}})) \quad \forall \alpha_{\mathcal{T}} \in D^k_{\mathcal{T}}.$$  

**(30)**

Problem (30) is well-posed, and computing $R^k_{TF} v_T$ requires to invert the boundary mass matrix.

**Lemma 17 (Local principle of virtual work and law of action and reaction).** Denote by $u_h \in U^k_{h,0}$ a solution of problem (21) and, for all $T \in \mathcal{T}_h$ and all $F \in \mathcal{F}_T$, define the numerical traction

$$T_{TF}(u_T) := -\pi_T^F \sigma(\cdot, G^k_{s,T} u_T) n_{TF} + R^k_{TF} u_T.$$  

Then, for all $T \in \mathcal{T}_h$ we have the following discrete principle of virtual work: For all $v_T \in \mathbb{P}^k(T; \mathbb{R}^d)$,

$$\int_T \sigma(\cdot, G^k_{s,T} u_T) : \nabla v_T + \sum_{F \in \mathcal{F}_T} \int_F T_{TF}(u_T) \cdot v_T = \int_T f \cdot v_T,$$

**(31)**

and, for any interface $F \in \mathcal{F}_{T_1} \cap \mathcal{F}_{T_2}$, the numerical tractions satisfy the law of action and reaction:

$$T_{T_1 F}(u_{T_1}) + T_{T_2 F}(u_{T_2}) = 0.$$

**(32)**
Proof. For all $T \in \mathcal{T}_h$, use the definition (17) of $G^k_{s,T}v_T$ with $\boldsymbol{\tau} = \pi_T^s \sigma(G^k_{s,T}u_T)$ in $A_h$ and the rewriting (29) of $s_T$ together with the definition (30) of $R^k_{TF}$ to infer that it holds, for all $v_h \in \mathcal{U}^k_h$,\[
abla \cdot v_h = A_h(u_h, v_h) + s_h(u_h, v_h) = \sum_{T \in \mathcal{T}_h} \left( \int_T \sigma(\cdot, G^k_{s,T}u_T) : \nabla s v_T + \sum_{F \in \mathcal{F}_T} \int_F (\pi^k_T \sigma(\cdot, G^k_{s,T}u_T)n_{TF} - R^k_{TF}u_T) \cdot (v_F - v_T) \right),\]
where to cancel $\pi^k_T$ inside the first integral in the second line we have used the fact that $\nabla s v_T \in \mathbb{P}^{k-1}(T; \mathbb{R}^{d \times d})$ for all $T \in \mathcal{T}_h$. Selecting $v_h$ such that $v_T = 0$ for all $T \in \mathcal{T}_h \setminus \{T\}$ and $v_{\partial} = 0$ for all $F \in \mathcal{F}_h$, we obtain (31). On the other hand, selecting $v_h$ such that $v_T = 0$ for all $T \in \mathcal{T}_h$, $v_{\partial}$ spans $\mathbb{P}^k(F; \mathbb{R}^d)$ for a selected interface $F \in \mathcal{F}_T \cap \mathcal{F}_{T'}$, and $v_{\partial'} = 0$ for all $F' \in \mathcal{T}_h \setminus \{F\}$ yields (32). \[\square\]

6 Numerical results

In this section we present a comprehensive set of numerical tests to assess the properties of our method using the models of Examples 2, 3, and 5 (cf. also Remark 6). Note that an important step in the implementation of HHO methods consists in selecting a basis for each of the polynomial spaces that appear in the construction. In the numerical tests of the present section, for all $T \in \mathcal{T}_h$, we take as a basis for $\mathbb{P}^k(T; \mathbb{R}^d)$ the Cartesian product of the monomials in the translated and scaled coordinates $(h_T^{-1}(x_i - x_T)), 1 \leq i \leq d'$ where $x_T$ is the barycenter of $T$. Similarly, for all $F \in \mathcal{F}_h$, we define a basis for $\mathbb{P}^k(F; \mathbb{R}^d)$ by taking the monomials with respect to a local frame scaled using the face diameter $h_F$ and the middle point of $F$. Further details on implementation aspects are given in [20, Section 6.1].

6.1 Convergence for the Hencky–Mises model

In order to check the error estimates stated in Theorem 14, we first solve a manufactured two-dimensional hyperelasticity problem. We consider the Hencky–Mises model with $\Phi(\rho) = \mu(e^{-\rho} + 2\rho)$ and $\alpha = \lambda + \mu$ in (8), so that conditions (9) is satisfied. This choice leads to the following stress-strain relation:
\[
\sigma(\nabla u) = ((\lambda - \mu) + \mu e^{-\text{dev}(\nabla u)}) \text{tr}(\nabla u) I_d + \mu(2 - e^{-\text{dev}(\nabla u)}) \nabla u.
\]
We consider the unit square domain $\Omega = (0, 1)^2$ and take $\mu = 2$, $\lambda = 1$, and an exact displacement $u$ given by
\[
u(x) = (\sin(\pi x_1) \sin(\pi x_2), \sin(\pi x_1) \sin(\pi x_2)).
\]
The volumetric load $f = -\nabla \sigma(\nabla u)$ is inferred from the exact solution $u$. In this case, since the selected exact displacement vanishes on $\Gamma$, we simply consider homogeneous Dirichlet conditions. We consider the triangular, hexagonal, Voronoi, and nonmatching quadrangular mesh families depicted in Figure 2 and polynomial degrees $k$ ranging from 1 to 4. The nonmatching mesh is simply meant
to show that the method supports nonconforming interfaces: refining in the corner has no particular
meaning for the selected solution. The initialization of our iterative linearization procedure (Newton
scheme) is obtained solving the linear elasticity model. This initial guess leads to a 40% reduction of
the number of iterations with respect to a null initial guess. The energy-norm orders of convergence
(OCV) displayed in the third column of Tables 1–4 are in agreement with the theoretical predictions.
In particular, it is observed that the optimal convergence in $h^{k+1}$ is reached for the triangular,
nonmatching Cartesian, and hexagonal meshes for $1 \leq k \leq 3$, whereas for $k = 4$ the asymptotic
convergence order does not appear to have been reached in the last mesh refinement. It can also
be observed in Table 2 that the convergence rate exceeds the estimated one on the locally refined
Cartesian mesh for $k = 1$ and $k = 2$. For the sake of completeness, we also display in the fourth
column of Tables 1–4 the $L^2$-norm of the error defined as the difference between the $L^2$-projection $\pi_h u$ of the
exact solution on $\mathbb{P}_k^h(\mathbb{T}_h; \mathbb{R}^d)$ and the broken polynomial function $u_h$ obtained from element-based
DOFs, while in the fifth column we display the corresponding observed convergence rates. In this
case, orders of convergence up to $h^{k+2}$ are observed.

6.2 Tensile and shear test cases

![Figure 3: Tensile test description and resulting stress components for the linear case. Values in $10^5$Pa](image)

![Figure 4: Shear test description and resulting stress components for the linear case. Values in $10^5$Pa](image)

We next consider the two test cases schematically depicted in Figures 3 and 4. On the unit square
domain $\Omega$, we solve problem (1) considering three different models of hyperelasticity (see Remark 6):

(i) **Linear.** The linear model corresponding to the stored energy density function (7) with Lamé’s
parameters

\[
\lambda = 11 \times 10^5 \text{Pa}, \quad \mu = 82 \times 10^4 \text{Pa}. \tag{34}
\]

(ii) **Hencky–Mises.** The Hencky–Mises model (4) obtained by taking $\Phi(\rho) = \mu(\frac{\rho}{2} + (1 + \rho)^{1/2})$ and

$\alpha = \lambda + \mu$ in (8), with $\lambda, \mu$ as in (34) (also in this case conditions (9) hold). This choice leads to

\[
\sigma(\nabla_s u) = ((\lambda + \frac{\mu}{2}) - \frac{\mu}{2}(1 + \text{dev}(\nabla_s u))^{-1/2}) \text{tr}(\nabla_s u) I_d + \mu(1 + \text{dev}(\nabla_s u))^{-1/2} \nabla_s u. \tag{35}
\]
The Lamé’s functions of the previous relation are inspired from those proposed in [5, Section 5.1]. In particular, the function $\hat{\mu}(\rho) = \mu(1 + (1 + \text{dev}(\nabla u))^2)$ corresponds to the Carreau law for viscoplastic materials.

(iii) **Second-order.** The second-order model (6) with Lamé’s parameter as in (34) and second-order moduli

$$A = 11 \times 10^6 \text{Pa}, \quad B = -48 \times 10^5 \text{Pa}, \quad C = 13.2 \times 10^5 \text{Pa}.$$  

These values correspond to the estimates provided in [34] for the Armco Iron. We recall that the second-order elasticity stress-strain relation does not satisfy in general the assumptions under which we are able to prove the convergence and error estimates. In particular, we observe that the stored energy density function defined in (10) is not convex.

The bottom part of the boundary of the domain is assumed to be fixed, the normal stress is equal to zero on the two lateral parts, and a traction is imposed at the top of the boundary. So, mixed boundary conditions are imposed as follows

$$u = 0 \quad \text{on} \quad \{x \in \Gamma, x_1 = 0\}, \quad \text{(36a)}$$

$$\sigma n = T \quad \text{on} \quad \{x \in \Gamma, x_2 = 1\}, \quad \text{(36b)}$$

$$\sigma n = 0 \quad \text{on} \quad \{x \in \Gamma, x_1 = 0\}, \quad \text{(36c)}$$

$$\sigma n = 0 \quad \text{on} \quad \{x \in \Gamma, x_1 = 1\}. \quad \text{(36d)}$$

For the tensile case, we impose a vertical traction at the top of the boundary equal to $T = (0, 3.2 \times 10^5 \text{Pa})$. This type of boundary conditions produces large normal stresses (i.e., the diagonal components of $\sigma$) and minor shear stresses (i.e., the off-diagonal components of $\sigma$). It can be observed in Figure 3, where the components of the stress tensor are depicted for the linear case. In Figure 5 we plot the stress norm on the deformed domain obtained for the three hyperelasticity models. The results of Fig. 3, 4, 5, and 6 are obtained on a mesh with 3584 triangles (corresponding to a typical mesh-size of $3.84 \times 10^{-3}$) and with polynomial degree $k = 2$. Obviously, the symmetry of the results is visible, and we observe that the three displacement fields are very close. This is motivated by the fact that, with our choice of the parameters in (34) and in (35), the linear model exactly corresponds to the linear approximation at the origin of the nonlinear ones. The maximum value of the stress concentrates on the two bottom corners due to the homogeneous Dirichlet condition that totally locks the displacement when $x_1 = 0$. The repartition of the stress on the domain with the second-order model is visibly different from those obtained with the linear and Hencky–Mises models. At the energy level, we also have a higher difference between the second-order model and the linear one since $|E_{\text{lin}} - E_{\text{hm}}|/E_{\text{lin}} = 0.44\%$ while $|E_{\text{lin}} - E_{\text{snd}}|/E_{\text{lin}} = 4.45\%$, where $E_\bullet$ is the total elastic energy obtained by integrating over the domain the strain energy density functions defined by (7), (8), and (10):

$$E_\bullet := \int_\Omega \Psi_\bullet, \quad \text{with} \quad \bullet \in \{\text{lin, hm, snd}\}.$$
The reference values for the total energy, used in Figure 7 in order to assess convergence, are obtained on a fine Cartesian mesh having a mesh-size of $1.95 \times 10^{-3}$ and $k = 3$.

For the shear case, we consider an horizontal traction equal to $T = (4.5 \times 10^3 \text{Pa}, 0)$ which induces the stress pattern illustrated in Figure 4. The computed stress norm on the deformed domain is depicted in Figure 6, and we can see that the displacement fields associated with the three models are very close as for the tensile test case. Here, the maximum values of the stress are localized in the lower part of the domain near the lateral parts. Unlike the tensile test, the difference between the three models is tiny as confirmed by the elastic energy equal to 3180 J, 3184 J, and 3190 J respectively. The decreasing of the energy difference in comparison with the previous test can be explained by the fact that the value of the Neumann boundary data on the top is divided by a factor 7 in order to obtain maximum displacements roughly equal to 15%.

7 Analysis

We collect here the proofs of the results stated in Section 4.4. To alleviate the notation, from this point on we abridge into $a \lesssim b$ the inequality $a \leq C b$ with real number $C > 0$ independent of $h$.

7.1 Existence and uniqueness

Proof of Theorem 7. 1) Existence. We follow the argument of [13, Theorem 3.3]. If $(E, \langle \cdot, \cdot \rangle_E, \| \cdot \|_E)$ is a Euclidean space and $\Phi : E \to E$ is a continuous map such that $\frac{\langle u(x), x \rangle_E}{\| x \|_E} \to +\infty$, as $\| x \|_E \to +\infty$, then $\Phi$ is surjective. We take $E = U_{k,0}^h$, endowed with the inner product

$$
(\mathbf{v}_h, \mathbf{w}_h)_{c,h} := \sum_{T \in \mathcal{T}_h} \left( \int_T \nabla \mathbf{v}_T : \nabla \mathbf{w}_T + \sum_{F \in \mathcal{F}_T} \frac{1}{|F|} \int_F (\mathbf{v}_F - \mathbf{v}_T) \cdot (\mathbf{w}_F - \mathbf{w}_T) \right),
$$

and we define $\Phi : U_{k,0}^h \to U_{k,0}^h$ such that, for all $\mathbf{v}_h \in U_{k,0}^h$, $(\Phi(\mathbf{v}_h), \mathbf{w}_h)_{c,h} = a_h(\mathbf{v}_h, \mathbf{w}_h)$ for all $\mathbf{w}_h \in U_{k,0}^h$. The coercivity (2d) of $\sigma$ together with the norm equivalence (25) yields $(\Phi(\mathbf{v}_h), \mathbf{w}_h)_{c,h} \geq \min \{1, \sigma \} |\mathbf{v}_h|_{1,c}^2 |\mathbf{w}_h|_{1,c}^2$ for all $\mathbf{v}_h \in U_{k,0}^h$, so that $\Phi$ is surjective. Let now $\mathbf{y}_h \in U_{k,0}^h$ be such that $(\mathbf{y}_h, \mathbf{w}_h)_{c,h} = \int_T f \cdot \mathbf{w}_h$ for all $\mathbf{w}_h \in U_{k,0}^h$. By the surjectivity of $\Phi$, there exists $\mathbf{u}_h \in U_{k,0}^h$ such that $\Phi(\mathbf{u}_h) = \mathbf{y}_h$. By definition of $\Phi$ and $\mathbf{y}_h$, $\mathbf{u}_h$ is a solution to the problem (21).

2) Uniqueness. Let $\mathbf{u}_{h,1}, \mathbf{u}_{h,2} \in U_{k,0}^h$ solve (21). We assume $\mathbf{u}_{h,1} \neq \mathbf{u}_{h,2}$ and proceed by contradiction. Subtracting (21) for $\mathbf{u}_{h,2}$ from (21) for $\mathbf{u}_{h,1}$, it is inferred that $a_h(\mathbf{u}_{h,1}, \mathbf{u}_{h,1}) - a_h(\mathbf{u}_{h,2}, \mathbf{u}_{h,1}) = 0$ for all $\mathbf{v}_h \in U_{k,0}^h$. Hence in particular, taking $\mathbf{v}_h = \mathbf{u}_{h,1} - \mathbf{u}_{h,2}$ we obtain that

$$
a_h(\mathbf{u}_{h,1}, \mathbf{u}_{h,1} - \mathbf{u}_{h,2}) - a_h(\mathbf{u}_{h,2}, \mathbf{u}_{h,1} - \mathbf{u}_{h,2}) = 0
$$

Figure 6: Shear test case: Stress norm on the deformed domain. Values in $10^3 \text{Pa}$
Figure 7: Energy vs $h$, tensile and shear test cases
On the other hand, owing to the strict monotonicity of $\varphi$ and to the fact that the bilinear form $s_h$ is positive semidefinite, we have that

$$a_h(\mathbf{u}_{h,1}, \mathbf{u}_{h,1} - \mathbf{u}_{h,2}) - a_h(\mathbf{u}_{h,2}, \mathbf{u}_{h,1} - \mathbf{u}_{h,2}) = \int_{\Omega} (\varphi(\cdot, G_{s,h}^k\mathbf{u}_{h,1}) - \varphi(\cdot, G_{s,h}^k\mathbf{u}_{h,2})) : G_{s,h}^k(\mathbf{u}_{h,1} - \mathbf{u}_{h,2}) + s_h(\mathbf{u}_{h,1} - \mathbf{u}_{h,2}, \mathbf{u}_{h,1} - \mathbf{u}_{h,2}) > 0.$$ 

Hence, $\mathbf{u}_{h,1} = \mathbf{u}_{h,2}$ and the conclusion follows. \qed

### 7.2 Convergence

This section contains the proof of Theorem 9 preceded by a discrete Rellich–Kondrachov Lemma (cf. [9, Theorem 9.16]) and a proposition showing the approximation properties of the discrete symmetric gradient $G_{s,h}^k$.

**Lemma 18** (Discrete compactness). *Let the assumptions of Theorem 9 hold. Let $(v_h)_{h \in H} \in (\mathcal{U}_h^k)_{h \in H}$, and assume that there is a real number $C > 0$ such that

$$\|v_h\|_{L^\infty} \leq C \quad \forall h \in H.$$ \hspace{1cm} (37)

Then, for all $q$ such that $1 \leq q < +\infty$ if $d = 2$ or $1 \leq q \leq 6$ if $d = 3$, the sequence $(v_h)_{h \in H} \in (\mathcal{P}(\mathcal{T}_h; \mathbb{R}^d))_{h \in H}$ is relatively compact in $L^q(\Omega; \mathbb{R}^d)$. As a consequence, there is a function $v \in L^q(\Omega; \mathbb{R}^d)$ such that as $h \to 0$, up to a subsequence, $v_h \to v$ strongly in $L^q(\Omega; \mathbb{R}^d)$.

**Proof.** In the proof we use the same notation for functions in $L^2(\Omega; \mathbb{R}^d) \subset L^1(\Omega; \mathbb{R}^d)$ and for their extension by zero outside $\Omega$. Let $(v_h)_{h \in H} \in (\mathcal{U}_h^k)_{h \in H}$ be such that (37) holds. Define the space of integrable functions with bounded variation $BV(\mathbb{R}^d) := \{v \in L^1(\mathbb{R}^d; \mathbb{R}^d) : \|v\|_{BV} < +\infty\}$, where

$$\|v\|_{BV} := \sum_{i=1}^d \sup \left\{ \int_{\mathbb{R}^d} v \cdot \partial_i \phi \mid \phi \in C^c(\mathbb{R}^d; \mathbb{R}^d), \|\phi\|_{L^\infty(\mathbb{R}^d)} \leq 1 \right\}.$$ 

Here, $\partial_i \phi$ denotes the $i$-th column of $\nabla \phi$. Let $\phi \in C_c^\infty(\mathbb{R}^d; \mathbb{R}^d)$ with $\|\phi\|_{L^\infty(\mathbb{R}^d)} \leq 1$. Integrating by parts and using the fact that $\sum_{T \in T_h} \sum_{F \in F_T} \int_F (v_F \cdot \phi) n_T = 0$, we have that

$$\int_{\mathbb{R}^d} v_h \cdot \partial_i \phi = \sum_{T \in T_h} \int_T ((\nabla \phi)^T v_T)_i = - \sum_{T \in T_h} \left( \int_T (\nabla v_T)^T \phi_i + \sum_{F \in F_T} \int_F (v_F \cdot \phi - v_T \cdot \phi)(n_T F) \right),$$

$$\leq \sum_{T \in T_h} \left( \int_T \sum_{j=1}^d |(\nabla v_T)_{ji}| + \sum_{F \in F_T} \int_F \sum_{j=1}^d |(v_F - v_T)(n_T F)| \right),$$

where, in order to pass to the second line, we have used $\|\phi\|_{L^\infty(\mathbb{R}^d)} \leq 1$. Therefore, summing over $i \in \{1, \ldots, d\}$, observing that, for all $T \in T_h$ and all $F \in F_T$, we have $\sum_{i=1}^d |(n_T F)|_i \leq d^{1/2}$, and using the Lebesgue embeddings arising from the Hölder inequality on bounded domain, leads to

$$\|v_h\|_{BV} \lesssim \sum_{T \in T_h} \left( |T|^{1/2}_d |\nabla v_T|_T + \sum_{F \in F_T} |F|^{1/2}_{d-1} |v_F - v_T|_F \right),$$

where $|.|_d$ denotes the $d$-dimensional Hausdorff measure. Moreover, using the Cauchy–Schwarz inequality together with the geometric bound $|F|_{d-1} h_F \lesssim |T|_d$, we obtain that

$$\|v_h\|_{BV} \lesssim \Omega^{1/2}_d \left( \sum_{T \in T_h} |\nabla v_T|_T^2 + \sum_{F \in F_T} h_T^{-1} |v_F - v_T|_F^2 \right)^{1/2}.$$ 

Thus, using the discrete Korn inequality (26), it is readily inferred that

$$\|v_h\|_{BV} \lesssim \|v_h\|_{L^\infty} \lesssim 1.$$ \hspace{1cm} (38)
Therefore, up to a subsequence, if Sobolev embeddings \( \sigma \) and \( \tau \) commute, then
\[
\|v_h\|_{L^q(\Omega; R^d)} \lesssim \left( \sum_{T \in \mathcal{T}_h} \left[ \|\nabla v_T\|_T^2 + \sum_{F \in \mathcal{F}_T} h_F^{-1} \|v_F - v_T\|_F^2 \right] \right)^{1/2} \lesssim 1,
\]

Thus, we can complete the proof by means of the interpolation inequality [9, Remark 2 p. 93]. For all \( h, h' \in \mathcal{H} \) we have with \( \theta := \frac{r - q}{d(r - 1)} \in (0, 1) \),
\[
\|v_h - v_{h'}\|_{L^q(\Omega; R^d)} \lesssim \|v_h - v_{h'}\|_{L^q(\Omega; R^d)}^{\theta} \|v_h - v_{h'}\|_{L^q(\Omega; R^d)}^{1-\theta} \lesssim \|v_h - v_{h}\|_{L^q(\Omega; R^d)}^{\theta}.
\]

Therefore, up to a subsequence, \( (v_h)_{h \in \mathcal{H}} \) is a Cauchy sequence in \( L^q(\Omega; R^d) \), so it converges.

The following consistency properties of the symmetric gradient operator \( \mathcal{G}_{s,T}^k \) defined by \( (19) \) play a fundamental role in the proof of Theorem 9.

**Proposition 19** (Consistency of the discrete symmetric gradient operator). Let \( (T_h)_{h \in \mathcal{H}} \) be a regular mesh sequence, and let \( \mathcal{G}_{s,T}^k \) be as in \( (19) \) with \( \mathcal{G}_{s,T}^k \) defined by \( (17) \) for all \( T \in \mathcal{T}_h \).

1) Strong consistency. For all \( \mathbf{v} \in H^1(\Omega; R^d) \) with \( \mathbf{I}_k^T \) defined by \( (15) \), it holds as \( h \to 0 \)
\[
\mathcal{G}_{s,T}^k \mathbf{I}_k^T \mathbf{v} \to \nabla \mathbf{v} \quad \text{strongly in} \quad L^2(\Omega; R^{d \times d}).
\]

2) Sequential consistency. For all \( h \in \mathcal{H} \) and all \( \mathbf{v} \in H^1(\Omega; R^{d \times d}) \), denoting by \( \gamma_m(\tau) \) the normal trace of \( \tau \) on \( \Gamma \), it holds
\[
\lim_{h \to 0} \left( \max_{\mathbf{v}_h \in \mathcal{U}_k^h | \mathcal{U}_k^h, \|h\|_{\mathcal{H}} = 1} \left[ \int_{\Omega} \mathcal{G}_{s,T}^k \mathbf{v}_h : \mathbf{v} + \mathbf{v}_h \cdot (\nabla \cdot \mathbf{v}) - \int_{\Gamma} \mathbf{v}_h \cdot \gamma_m(\mathbf{v}) \right] \right) = 0.
\]

**Proof.** 1) Strong consistency. We first assume that \( \mathbf{v} \in H^2(\Omega; R^d) \). Owing to the commutativity property \( (18) \) and the approximation property \( (13a) \) with \( m = 1 \) and \( s = 2 \), it is inferred that \( \|\mathcal{G}_{s,T}^k \mathbf{I}_k^T \mathbf{v} - \nabla \mathbf{v}\|_{\mathcal{H}(T; R^d)} \lesssim h\|\mathbf{v}\|_{H^2(T; R^d)} \). Squaring, summing over \( T \in \mathcal{T}_h \), and taking the square root of the resulting inequality gives
\[
\|\mathcal{G}_{s,T}^k \mathbf{I}_k^T \mathbf{v} - \nabla \mathbf{v}\| \lesssim h\|\mathbf{v}\|_{H^2(\Omega; R^d)}.
\]

If \( \mathbf{v} \in H^1(\Omega; R^d) \) we reason by density, namely we take a sequence \( (\mathbf{v}_\epsilon)_{\epsilon > 0} \subset H^2(\Omega; R^d) \) that converges to \( \mathbf{v} \) in \( H^1(\Omega; R^d) \) as \( \epsilon \to 0 \) and, using twice the triangular inequality, we write
\[
\|\mathcal{G}_{s,T}^k \mathbf{I}_k^T \mathbf{v} - \nabla \mathbf{v}\| \lesssim \|\mathcal{G}_{s,T}^k \mathbf{I}_k^T (\mathbf{v} - \mathbf{v}_\epsilon)\| + \|\mathcal{G}_{s,T}^k \mathbf{I}_k^T \mathbf{v}_\epsilon - \nabla \mathbf{v}_\epsilon\| + \|\nabla \mathbf{v}(\mathbf{v} - \mathbf{v}_\epsilon)\|.
\]

By \( (41) \), the second term in the right-hand side tends to 0 as \( h \to 0 \). Moreover, owing to the compactness property \( (18) \) and the \( H^1 \)-boundedness of \( \pi_T^k \), one has
\[
\|\mathcal{G}_{s,T}^k \mathbf{I}_k^T (\mathbf{v} - \mathbf{v}_\epsilon)\| = \left( \sum_{T \in \mathcal{T}_h} \|\pi_T^k \nabla \mathbf{v}_\epsilon\|_{L^2}^2 \right)^{1/2} \lesssim \left( \sum_{T \in \mathcal{T}_h} \|\nabla \mathbf{v}_\epsilon\|_{L^2}^2 \right)^{1/2} \lesssim \|\nabla \mathbf{v}_\epsilon\| \lesssim \|\mathbf{v}_\epsilon\|.
\]

Therefore, taking the supremum limit as \( h \to 0 \) and then the supremum limit as \( \epsilon \to 0 \), concludes the proof of \( (39) \) (notice that the order in which the limits are taken is important).
2) Sequential consistency. In order to prove (40) we observe that, by the definitions (19) of $G_{s,h}$ and (17b) of $G_{s,T}^k$ one has, for all $\tau \in H^1(\Omega;\mathbb{R}^{d \times d})$ and all $v_h \in U_h$,

\[
\int_{\Omega} G_{s,T}^k v_h : \tau = \sum_{T \in \mathcal{T}_h} \int_T G_{s,T}^k v_T : \tau
\]

= \sum_{T \in \mathcal{T}_h} \int_T \left( G_{s,T}^k v_T - \nabla_s v_T \right) : (\tau - \pi_T^0 \tau) + \sum_{T \in \mathcal{T}_h} \int_T \left( G_{s,T}^k v_T - \nabla_s v_T \right) : \pi_T^0 \tau + \sum_{T \in \mathcal{T}_h} \int_T \nabla_s v_T : \tau
\]

= \Sigma_1 + \sum_{T \in \mathcal{T}_h} \sum_{F \in F_T} \int_F (v_F - v_T) \cdot (\pi_T^0 \tau) n_{TF} + \sum_{T \in \mathcal{T}_h} \int_T \nabla_s v_T : \tau
\]

= \Sigma_1 + \sum_{T \in \mathcal{T}_h} \sum_{F \in F_T} \int_F (v_F - v_T) \cdot (\pi_T^0 \tau - \tau) n_{TF} - \sum_{T \in \mathcal{T}_h} \int_T v_T \cdot (\nabla \tau) + \sum_{F \in F_h} \int_F v_F \cdot (\tau n_{TF})
\]

= \Sigma_1 + \Sigma_2 - \int_{\Omega} v_h \cdot (\nabla \tau) + \int_{\Gamma} v_{\Gamma,h} \cdot \gamma_\tau(\tau). \tag{43}
\]

In the fourth line, we used an element-wise integration by parts together with the relation

\[
\sum_{T \in \mathcal{T}_h} \sum_{F \in F_T} \int_F v_F \cdot (\tau n_{TF}) = \sum_{F \in F_h} \int_F v_F \cdot (\tau n_{TF} + \tau n_{T_2F}) = 0,
\]

where for all $F \in F_h$, $T_1, T_2 \in \mathcal{T}_h$ are such that $F \subset \partial T_1 \cap \partial T_2$. Owing to (43), the conclusion follows once we prove that $|\Sigma_1 + \Sigma_2| \lesssim h^2 \|v_h\|_{\mathcal{C}_h} \|\tau\|_{H^1(\Omega;\mathbb{R}^{d \times d})}$. By (13a) (with $m = 0$ and $s = 1$) we have $|\tau - \pi_T^0 \tau| \lesssim h^2 |\tau|_{H^1(\Omega;\mathbb{R}^{d \times d})}$ and thus, using the Cauchy–Schwarz and triangle inequalities followed by the norm equivalence (25),

\[
|\Sigma_1| \lesssim \left( \sum_{T \in \mathcal{T}_h} \|G_{s,T}^k v_T - \nabla_s v_T\|^2 \right)^{1/2} \left( \sum_{T \in \mathcal{T}_h} \|\tau - \pi_T^0 \tau\|^2 \right)^{1/2}
\]

\[
\lesssim h \left( \|G_{s,T}^k v_h - \nabla_s v_h\|^2 + \|v_h\|^2_{\mathcal{C}_h} \right)^{1/2} \|\tau\|_{H^1(\Omega;\mathbb{R}^{d \times d})} \lesssim h^2 \|v_h\|_{\mathcal{C}_h} \|\tau\|_{H^1(\Omega;\mathbb{R}^{d \times d})}. \tag{44}
\]

In a similar way, we obtain an upper bound for $\Sigma_2$. By (13b) (with $m = 0$ and $s = 1$), for all $F \in \mathcal{F}_T$, we have $|\tau - \pi_T^0 \tau|_F \lesssim h^{1/2} |\tau|_{H^1(\Omega;\mathbb{R}^{d \times d})} \lesssim h^{1/2} |\tau|_{H^1(\Omega;\mathbb{R}^{d \times d})}$ and thus, using the Cauchy–Schwarz inequality,

\[
|\Sigma_2| \lesssim \sum_{T \in \mathcal{T}_h} \sum_{F \in \mathcal{F}_T} h^{1/2} \|v_F - v_T\|_F |\tau|_{H^1(\Omega;\mathbb{R}^{d \times d})} \lesssim h \|v_h\|_{\mathcal{C}_h} \|\tau\|_{H^1(\Omega;\mathbb{R}^{d \times d})}. \tag{45}
\]

Owing to (44) and (45), the triangle inequality $|\Sigma_1 + \Sigma_2| = |\Sigma_1| + |\Sigma_2|$ yields the conclusion.

We are now ready to prove convergence.

Proof of Theorem 9. The proof is subdivided into four steps: in Step 1 we prove a uniform a priori bound on the solutions of the discrete problem (21); in Step 2 we infer the existence of a limit for the sequence of discrete solutions and investigate its regularity; in Step 3 we show that this limit solves the continuous problem (11); finally, in Step 4 we prove strong convergence.

Step 1: A priori bound. We start by showing the following uniform a priori bound on the sequence of discrete solutions:

\[
\|u_h\|_{\mathcal{C}_h} \lesssim C \|f\|, \tag{46}
\]

where the real number $C > 0$ only depends on $\Omega, \alpha, \gamma, \beta,$ and $k$. Making $v_h = u_h$ in (21) and using the coercivity property (24) of $\sigma$ in the left-hand side together with the Cauchy–Schwarz inequality in the right-hand side yields

\[
\sum_{T \in \mathcal{T}_h} \frac{1}{2} \|G_{s,T}^k u_T\|^2_T + \sum_{F \in \mathcal{F}_h} \frac{\gamma_F}{h_F} \|\Delta_{TF}^k u_T\|^2_F \leq \|f\| \|u_h\|.
\]
Owing to the norm equivalence (25), and using the discrete Korn inequality (26) to estimate the right-hand side of the previous inequality, it is inferred that

\[ \eta^{-1} \min(1, C) \|u_h\|_{c,h}^2 \leq \|f\|_c \leq C_K \|f\| \|u_h\|_{c,h}. \]

Dividing by \(\|u_h\|_{c,h}\) yields (46) with \(C = \eta \min(1, C)\).

**Step 2: Existence of a limit and regularity.** Let \(1 \leq q < +\infty\) if \(d = 2\) or \(1 \leq q < 6\) if \(d = 3\). Owing to the a priori bound (46) and the norm equivalence (25), the sequences \(\|u_h\|_{c,h}\) and \(\{(G_{s,h}u_h)\}_{h \in H}\) are uniformly bounded. Therefore, Lemma 18 and the Kakutani theorem [9, Theorem 3.17] yield the existence of \(u \in L^q(\Omega; \mathbb{R}^d)\) and \(G_{s,h}u_h \rightharpoonup G\) weakly in \(L^2(\Omega; \mathbb{R}^{d \times d})\) such that as \(h \to 0\), up to a subsequence,

\[ u_h \to u \text{ strongly in } L^q(\Omega; \mathbb{R}^d) \text{ and } G_{s,h}u_h \rightharpoonup G \text{ weakly in } L^2(\Omega; \mathbb{R}^{d \times d}). \] (47)

This together with the fact that \(u_{h,\Gamma} = 0\) on \(\Gamma\), shows that, for any \(\tau \in H^1(\Omega; \mathbb{R}^{d \times d})\),

\[
\left| \int_{\Omega} G : \tau + u \cdot (\nabla \tau) \right| = \lim_{h \to 0} \left( \int_{\Omega} G_{s,h}u_h : \tau + u_h \cdot (\nabla \tau) - \int_{\Gamma} u_h,_{\Gamma} \cdot \gamma_n(\tau) \right) \leq \lim_{h \to 0} \left( \|u_h\|_{c,h} \max_{\Sigma \in \mathbb{L}^2, \|\Sigma\|_{\mathbb{L}^2} \leq 1} \left| \int_{\Omega} G_{s,h}u_h : \tau + v_h \cdot (\nabla \tau) - \int_{\Gamma} v_h,_{\Gamma} \cdot \gamma_n(\tau) \right| \right) = 0. \] (48)

To infer the previous limit we have used the uniform bound (46) on \(\|u_h\|_{c,h}\) and the sequential consistency (40) of \(G_{s,h}^k\). Applying (48) with \(\tau \in C_c^\infty(\Omega; \mathbb{R}^{d \times d})\) leads to \(\int_{\Omega} G : \tau + u \cdot (\nabla \tau) = 0\), thus \(G = \nabla u\) in the sense of distributions on \(\Omega\). As a result, owing to the isomorphism of Hilbert spaces between \(H^1(\Omega; \mathbb{R}^d)\) and \(\{v \in L^2(\Omega; \mathbb{R}^d) | \nabla \cdot v \in L^2(\Omega; \mathbb{R}^{d \times d})\}\) proved in [28, Theorem 3.1], we have \(u \in H^1(\Omega; \mathbb{R}^d)\). Using again (48) with \(\tau \in H^1(\Omega; \mathbb{R}^{d \times d})\) and integrating by parts, we obtain \(\int_{\Gamma} \gamma(u) \cdot \gamma_n(\tau) = 0\) with \(\gamma(u)\) denoting the trace of \(u\). As the set \(\{\gamma_n(\tau) : \tau \in H^1(\Omega; \mathbb{R}^{d \times d})\}\) is dense in \(L^2(\Gamma; \mathbb{R}^d)\), we deduce that \(\gamma(u) = 0\) on \(\Gamma\). In conclusion, with convergences up to a subsequence,

\[ u \in H^1_0(\Omega; \mathbb{R}^d), \ u_h \to u \text{ strongly in } L^q(\Omega; \mathbb{R}^d), \text{ and } G_{s,h}u_h \rightharpoonup \nabla u \text{ weakly in } L^2(\Omega; \mathbb{R}^{d \times d}). \]

**Step 3: Identification of the limit.** Let us now prove that \(u\) is a solution to (11). The growth property (2c) on \(\sigma\) and the bound on \(\{(G_{s,h}u_h)\}_{h \in H}\) ensure that the sequence \((\sigma(\cdot, G_{s,h}u_h))_{h \in H}\) is bounded in \(L^2(\Omega; \mathbb{R}^{d \times d})\). Hence, there exists \(\eta \in L^2(\Omega; \mathbb{R}^{d \times d})\) such that, up to a subsequence as \(h \to 0\),

\[ \sigma(\cdot, G_{s,h}u_h) \to \eta \text{ weakly in } L^2(\Omega; \mathbb{R}^{d \times d}). \] (49)

Plugging into (21) \(u_h = \Gamma^k \phi\), with \(\phi \in C_c^\infty(\Omega; \mathbb{R}^d)\), gives

\[ \int_{\Omega} \sigma(\cdot, G_{s,h}u_h) : G_{s,h}^k \phi = \int_{\Omega} f \cdot \pi^k_h \phi - s_h(u_h, \Gamma^k \phi), \] (50)

with \(\pi^k_h\) denoting the \(L^2\)-projector on the broken polynomial spaces \(P^k(\mathbb{T}_h; \mathbb{R}^d)\) and \(s_h\) defined by (23). Using the Cauchy–Schwarz inequality followed by the norm equivalence (25) to bound the first factor, we infer

\[ |s_h(u_h, \Gamma^k \phi)| \leq s_h(u_h, u_h)^{1/2} s_h(\Gamma^k \phi, \Gamma^k \phi)^{1/2} \leq \|u_h\|_{c,h} s_h(\Gamma^k \phi, \Gamma^k \phi)^{1/2}. \] (51)

It was proved in [20, Eq. (35)] using the optimal approximation properties of \(\nu_{T}^k F^k_T\) that it holds for all \(h \in H\), all \(T \in \mathbb{T}_h\), all \(v \in H^{k+2}(T; \mathbb{R}^d)\), and all \(F \in F_T\) that

\[ h_F^{1/2} \|\Delta_T^k F^k_T v\|_F \leq h_T^{k+1} \|v\|_{H^{k+2}(T; \mathbb{R}^d)}, \] (52)

19
with \( \Delta_{f,p}^k \) defined by (24). As a consequence, recalling the definition (23) of \( s_h \), we have the following convergence result:
\[
\forall v \in H^1(\Omega; \mathbb{R}^d) \cap H^2(\mathcal{T}_h; \mathbb{R}^d), \quad \lim_{h \to 0} s_h(L_h^k v, L_h^k v) = 0. \tag{53}
\]
Recalling the a priori bound (46) on the discrete solution and the convergence property (53), it follows from (51) that \( |s_h(u_h, L_h^k \phi)| \to 0 \) as \( h \to 0 \). Additionally, by the approximation property (13a) of the \( L^2 \)-projector, one has \( \pi_h^k \phi \to \phi \) strongly in \( L^2(\Omega; \mathbb{R}^d) \) and, by virtue of Proposition 19, that \( G_{s,h}^k L_h^k \phi \to \nabla \phi \) strongly in \( L^2(\Omega; \mathbb{R}^{d \times d}) \). Thus, we can pass to the limit \( h \to 0 \) in (50) and obtain
\[
\int_{\Omega} \eta : \nabla \phi = \int_{\Omega} f \cdot \phi. \tag{54}
\]
By density of \( C_c^\infty(\Omega; \mathbb{R}^d) \) in \( H_0^1(\Omega; \mathbb{R}^d) \), this relation still holds if \( \phi \in H_0^1(\Omega; \mathbb{R}^d) \). On the other hand, plugging \( \psi_h = \psi_h \) into (21) and using the fact that \( s_h(u_h, u_h) \geq 0 \), we obtain
\[
\mathcal{F}_h := \int_{\Omega} \sigma(\cdot, G_{s,h}^k u_h) : G_{s,h}^k u_h \leq \int_{\Omega} f \cdot u_h.
\]
Thus, using the previous bound, the strong convergence \( u_h \to u \), and (54), it is inferred that
\[
\lim_{h \to 0} \mathcal{F}_h \leq \int_{\Omega} f \cdot u = \int_{\Omega} \eta : \nabla \phi. \tag{55}
\]
We now use the monotonicity assumption on \( \sigma \) and the Minty trick [37] to prove that \( \eta = \sigma(\cdot, \nabla \phi) \). Let \( \Lambda \in L^2(\Omega; \mathbb{R}^{d \times d}) \) and write, using the monotonicity (2e) of \( \sigma \), the convergence (49) of \( \sigma(\cdot, G_{s,h}^k u_h) \), and the bound (55),
\[
0 \leq \lim_{h \to 0} \left( \int_{\Omega} \sigma(\cdot, G_{s,h}^k u_h) - \sigma(\cdot, \Lambda) : (G_{s,h}^k u_h - \Lambda) \right) \leq \int_{\Omega} (\eta - \sigma(\cdot, \Lambda)) : (\nabla \phi - \Lambda). \tag{56}
\]
Applying the previous relation with \( \Lambda = \nabla \phi + t \nabla \phi \), for \( t > 0 \) and \( v \in H_0^1(\Omega; \mathbb{R}^d) \), and dividing by \( t \), leads to
\[
0 \leq \pm \int_{\Omega} (\eta - \sigma(\cdot, \nabla \phi + t \nabla \phi)) : \nabla \phi v.
\]
Owing to the growth property (2c) and the Caratheodory property (2a) of \( \sigma \), we can let \( t \to 0 \) and pass the limit inside the integral and then inside the argument of \( \sigma \). In conclusion, for all \( v \in H_0^1(\Omega; \mathbb{R}^d) \), we infer
\[
\int_{\Omega} \sigma(\cdot, \nabla \phi) : \nabla \phi v = \int_{\Omega} \eta : \nabla \phi v = \int_{\Omega} f \cdot v,
\]
where we have used (54) with \( \phi = v \) in order to obtain the second equality. The above equation shows that \( \eta = \sigma(\cdot, \nabla \phi) \) and that \( \eta \) solves (11).

**Step 4: Strong convergence.** We prove that if \( \sigma \) is strictly monotone then \( G_{s,h}^k u_h \to \nabla \phi \) strongly in \( L^2(\Omega; \mathbb{R}^{d \times d}) \). We define the function \( D_h : \Omega \to \mathbb{R} \) such that
\[
D_h := (\sigma(\cdot, G_{s,h}^k u_h) - \sigma(\cdot, \nabla \phi)) : (G_{s,h}^k u_h - \nabla \phi).
\]
For all \( h \in \mathcal{H} \), the function \( D_h \) is non-negative as a result of the monotonicity property (2e) and, by (56) with \( \Lambda = \nabla \phi \), it is inferred that \( \lim_{h \to 0} \int_{\Omega} D_h = 0 \). Hence, \( (D_h)_{h \in \mathcal{H}} \) converges to 0 in \( L^1(\Omega) \) and, therefore, also almost everywhere on \( \Omega \) up to a subsequence. Let us take \( \bar{\eta} \in \Omega \) such that the above mentioned convergence hold at \( \bar{\eta} \). Developing the products in \( D_h \) and using the coercivity and growth properties (2d) and (2e) of \( \sigma \), one has
\[
D_h(\bar{\eta}) \geq \sigma(G_{s,h}^k u_h(\bar{\eta})) \|G_{s,h}^k u_h(\bar{\eta})\|_{d \times d} - 2\sigma\|G_{s,h}^k u_h(\bar{\eta})\|_{d \times d} \|\nabla \phi(\bar{\eta})\|_{d \times d} + \sigma\|\nabla \phi(\bar{\eta})\|_{d \times d}^2.
\]

20
Since the right hand side is quadratic in \( |G_{s,h}^k u_h(x)|_{d \times d} \) and \( (\mathcal{D}_h(x))_{h \in H} \) is bounded, we deduce that also \( (G_{s,h}^k u_h(x))_{h \in H} \) is bounded. Passing to the limit in the definition of \( \mathcal{D}_h(x) \) yields
\[
\sigma(\mathbf{f}, \mathbf{L}_x) - \sigma(\mathbf{f}, \nabla s \mathbf{u}(\mathbf{x})) : (\mathbf{L}_x - \nabla s \mathbf{u}(\mathbf{x})) = 0,
\]
where \( \mathbf{L}_x \) is an adherence value of \( (G_{s,h}^k u_h(x))_{h \in H} \). The strict monotonicity assumption forces \( \mathbf{L}_x = \nabla s \mathbf{u}(\mathbf{x}) \) to be the unique adherence value of \( (G_{s,h}^k u_h(x))_{h \in H} \), and therefore the sequence converges to this value. As a result,
\[
G_{s,h}^k u_h \to \nabla s \mathbf{u} \text{ a.e. on } \Omega.
\]
Using (55) together with Fatou’s Lemma, we see that
\[
\lim_{h \to 0} \int_{\Omega} \sigma(\cdot, G_{s,h}^k u_h) : G_{s,h}^k u_h = \int_{\Omega} \sigma(\cdot, \nabla s \mathbf{u}) : \nabla s \mathbf{u}.
\]
Moreover, owing to (57), \( (\sigma(\cdot, G_{s,h}^k u_h) : G_{s,h}^k u_h)_{h \in H} \) is a non-negative sequence converging almost everywhere on \( \Omega \). Using [25, Lemma 8.4] we see that this sequence also converges in \( L^1(\Omega) \) and, therefore, it is equi-integrable in \( L^1(\Omega) \). Thus, the coercivity (2d) of \( \sigma \) ensures that \( (G_{s,h}^k u_h)_{h \in H} \) is equi-integrable in \( L^2(\Omega; \mathbb{R}^{d \times d}) \) and Vitali’s theorem shows that
\[
G_{s,h}^k u_h \to \nabla s \mathbf{u} \text{ strongly in } L^2(\Omega; \mathbb{R}^{d \times d}).
\]

### 7.3 Error estimate

**Proof of Theorem 14.** For the sake of conciseness, throughout the proof we let \( \mathbf{u}_h := I^T_h \mathbf{u} \) and use the following abridged notations for the constraint field and its approximations:
\[
\varsigma := \sigma(\cdot, \nabla s \mathbf{u}) \text{ and, for all } T \in T_h, \varsigma_T := \sigma(\cdot, G_{s,T}^k \mathbf{u}_T) \text{ and } \hat{\varsigma}_T := \sigma(\cdot, G_{s,T}^k \hat{\mathbf{u}}_T).
\]
First we want to show that (28) holds assuming that
\[
\|\mathbf{u}_h - \mathbf{u}\|_{\epsilon,h} \leq h^{k+1 \choose 2} \left( \|\mathbf{u}\|_{H^{k+2}(T_h; \mathbb{R}^d)} + \|\varsigma\|_{H^{k+1}(T_h; \mathbb{R}^{d \times d})} \right).
\]
Using the triangle inequality, we obtain
\[
\|G_{s,h}^k \mathbf{u}_h - \nabla s \mathbf{u}\| + s_h(\mathbf{u}_h, \mathbf{u}_h)^{1/2} \leq \|G_{s,h}^k (\mathbf{u}_h - \hat{\mathbf{u}}_h)\| + s_h(\mathbf{u}_h - \hat{\mathbf{u}}_h, \mathbf{u}_h - \hat{\mathbf{u}}_h)^{1/2} + \|G_{s,h}^k \hat{\mathbf{u}}_h - \nabla s \mathbf{u}\| + s_h(\hat{\mathbf{u}}_h, \hat{\mathbf{u}}_h)^{1/2}.
\]
Using the norm equivalence (25) followed by (58) we obtain for the terms in the first line of (59)
\[
\|G_{s,h}^k (\mathbf{u}_h - \hat{\mathbf{u}}_h)\| + s_h(\mathbf{u}_h - \hat{\mathbf{u}}_h, \mathbf{u}_h - \hat{\mathbf{u}}_h)^{1/2} \leq h^{k+1 \choose 2} \left( \|\mathbf{u}\|_{H^{k+2}(T_h; \mathbb{R}^d)} + \|\varsigma\|_{H^{k+1}(T_h; \mathbb{R}^{d \times d})} \right).
\]
For the terms in the second line, using the approximation properties of \( G_{s,h}^k \), resulting from (18) together with (13a) for the first addend and (52) for the second, we get
\[
\|G_{s,h}^k \hat{\mathbf{u}}_h - \nabla s \mathbf{u}\| + s_h(\hat{\mathbf{u}}_h, \hat{\mathbf{u}}_h)^{1/2} \leq h^{k+1} \|\mathbf{u}\|_{H^{k+2}(T_h; \mathbb{R}^d)}.
\]
It only remains to prove (58), which we do in two steps: in **Step 1** we prove a basic estimate in terms of a conformity error, which is then bounded in **Step 2**.

**Step 1: Basic error estimate.** Using for all \( T \in T_h \) the strong monotonicity (27b) with \( \mathbf{\tau} = G_{s,T}^k \mathbf{u}_T \) and \( \eta = G_{s,T}^k \hat{\mathbf{u}}_T \), we infer
\[
\|G_{s,h}^k (\hat{\mathbf{u}}_h - \mathbf{u}_h)\|^2 \leq \sum_{T \in T_h} \int_T (\hat{\varsigma}_T - \varsigma_T) : G_{s,T}^k (\hat{\mathbf{u}}_T - \mathbf{u}_T).
\]
Owing to the norm equivalence (25) and the previous bound, we get
\[
\frac{1}{\epsilon,h} \left\| \hat{u}_h - u_h \right\|_{\epsilon,h}^2 \leq \sum_{T \in T_h} \int_T \varepsilon_T : G_{\epsilon,T}^h (\hat{u}_T - u_T) + s_h (\hat{u}_h - u_h, \hat{u}_h - u_h)
\]
\[
= a_h (\hat{u}_h, \hat{u}_h) - \int_{\Omega} f \cdot (\hat{u}_h - u_h).
\]
where we have used the discrete problem (21) to conclude. Hence, dividing by \(\|\hat{u}_h - u_h\|_{\epsilon,h}\) and passing to the supremum in the right-hand side, we arrive at the following error estimate:
\[
\frac{1}{\epsilon,h} \left\| \hat{u}_h - u_h \right\|_{\epsilon,h} \leq \sup_{v_h \in U_{\epsilon,h}^h} \mathcal{E}_h (v_h),
\]
with conformity error such that, for all \(v_h \in U_{\epsilon,h}^h\),
\[
\mathcal{E}_h (v_h) := \sum_{T \in T_h} \int_T \varepsilon_T : G_{\epsilon,T}^h v_T - \int_{\Omega} f \cdot v_h + s_h (\hat{u}_h, v_h).
\]

**Step 2: Bound of the conformity error.** We bound the quantity \(\mathcal{E}_h (v_h)\) defined above for a generic \(v_h \in U_{\epsilon,h}^h\). Denote by \(\mathcal{T}_1, \mathcal{T}_2,\) and \(\mathcal{T}_3\) the three addends in the right-hand side of (61).

Using for all \(T \in T_h\) the definition (17) of \(G_{\epsilon,T}^h\) with \(\tau = \pi_T^h \varepsilon_T\), we have that
\[
\mathcal{T}_1 = \sum_{T \in T_h} \left( \int_T \varepsilon_T : \nabla_s v_T + \sum_{F \in F_T} \int_F \pi_T^h \varepsilon_T n_{TF} \cdot (v_F - v_T) \right),
\]
where we have used the fact that \(\nabla_s v_T \in \mathbb{R}^{k-1}(T; \mathbb{R}^{d \times d})\) together with the definition (12) of the orthogonal projector to cancel \(\pi_T^h\) in the first term.

On the other hand, using the fact that \(f = -\nabla \cdot s\) a.e. in \(\Omega\) and integrating by parts element by element, we get that
\[
\mathcal{T}_2 = - \sum_{T \in T_h} \left( \int_T \varepsilon : \nabla_s v_T + \sum_{F \in F_T} \int_F \varepsilon n_{TF} \cdot (v_F - v_T) \right),
\]
where we have additionally used that \(\varepsilon_{|T}, n_{TF} + \varepsilon_{|T} n_{TF}, F = 0\) for all interfaces \(F \subset \partial T_1 \cap \partial T_2\) and that \(v_F\) vanishes on \(F\) (cf. (20)) to insert \(v_F\) into the second term.

Summing (62) and (63), taking absolute values, and using the Cauchy–Schwarz inequality to bound the right-hand side, we infer that
\[
|\mathcal{T}_1 + \mathcal{T}_2| \leq \left( \sum_{T \in T_h} (\|s - \varepsilon_T\|_{T}^2 + h_T \|s - \pi_T^h \varepsilon_T\|_{T}^2) \right)^{1/2} |v_h|_{\epsilon,h}.
\]
It only remains to bound the first factor. Let a mesh element \(T \in T_h\) be fixed. Using the Lipschitz continuity (27a) with \(\tau = G_{\epsilon,T}^h u_T\) and \(\eta = \nabla_s u\) and the optimal approximation properties of \(G_{\epsilon,T}^h I_T^h\) resulting from (18) together with (13a) with \(m = 1\) and \(s = k + 2\), leads to
\[
|s - \varepsilon_T|_T \leq \|\nabla_s u - G_{\epsilon,T}^h u_T\|_T \leq h^{k+1} |u|_{H^{k+2}(T; \mathbb{R}^d)},
\]
which provides an estimate for the first term inside the summation in the right-hand side of (64).

To estimate the second term, we use the triangle inequality, the discrete trace inequality of [19, Lemma 1.46], and the boundedness of \(\pi_T^h\) to write
\[
h_T^{1/2} \|s - \pi_T^h \varepsilon_T\|_{\mathcal{E}^d} \leq |\pi_T^h (s - \varepsilon_T)|_T + h_T^{1/2} \|s - \pi_T^h \varepsilon_T\|_{\mathcal{E}^d} \leq |s - \varepsilon_T|_T + h_T^{1/2} \|s - \pi_T^h \varepsilon_T\|_{\mathcal{E}^d}.
\]
The first term in the right-hand side is bounded by (65). For the second, using the approximation properties (13b) of $\pi^k_h$ with $m = 0$ and $s = k + 1$, we get $h^{1/2}_T |\chi - \pi^k_T |_{\mathcal{E}_h} \leq h^{k+1} |\chi|_{H^{k+1}(\mathcal{T}; \mathbb{R}^d)}$ so that, in conclusion,

$$h^{1/2}_T |\chi - \pi^k_T |_{\mathcal{E}_h} \leq h^{k+1} ( \|u\|_{H^{k+2}(\mathcal{T}; \mathbb{R}^d)} + \|\chi\|_{H^{k+1}(\mathcal{T}; \mathbb{R}^d)}) .$$  \hspace{1cm} (66)

Plugging the estimates (65) and (66) into (64) finally yields

$$|\mathcal{S}_1 + \mathcal{S}_2| \leq h^{k+1} ( \|u\|_{H^{k+2}(\mathcal{T}_h; \mathbb{R}^d)} + \|\chi\|_{H^{k+1}(\mathcal{T}_h; \mathbb{R}^d)}) \|\mathcal{S}_h\|_{\mathcal{E}_h}.$$  \hspace{1cm} (67)

It only remains to bound $\mathcal{S}_3 = s_h(\hat{u}_T, v_h)$. Using the Cauchy–Schwarz inequality, the definition (23) of $s_h$, the approximation property (52) of $\Delta^k_T \mathcal{F}$, and the norm equivalence (25), we infer

$$|\mathcal{S}_3| \leq \left( \sum_{T \in \mathcal{T}_h} \sum_{F \in \mathcal{F}_h} \frac{\gamma}{h_F} |\Delta^k_T \mathcal{F}_{\hat{u}_T}|^2 \right)^{1/2} s_h(\hat{u}_T, v_h)^{1/2} \leq h^{k+1} \|u\|_{H^{k+2}(\mathcal{T}_h; \mathbb{R}^d)} \|\mathcal{S}_h\|_{\mathcal{E}_h}.$$  \hspace{1cm} (68)

Using (67) and (68), we finally get that, for all $\mathcal{S}_h \in \mathcal{U}^k_h$,

$$\mathcal{E}_h(\mathcal{S}_h) \leq h^{k+1} ( \|u\|_{H^{k+2}(\mathcal{T}_h; \mathbb{R}^d)} + \|\chi\|_{H^{k+1}(\mathcal{T}_h; \mathbb{R}^d)}) \|\mathcal{S}_h\|_{\mathcal{E}_h}.$$  \hspace{1cm} (69)

Thus, using (69) to bound the right-hand side of (60), (58) follows. 

\[ \square \]

**A  Technical results**

This appendix contains the proof of the discrete Korn inequality (26).

**Proposition 20** (Discrete Korn inequality). Assume that the mesh further verifies the assumption of [8, Theorem 4.2] if $d = 2$ and [8, Theorem 5.2] if $d = 3$. Then, the discrete Korn inequality (26) holds.

**Proof.** Using the broken Korn inequality [8, Eq. (1.22)] on $H^1(\mathcal{T}_h; \mathbb{R}^d)$ followed by the Cauchy–Schwarz inequality, one has

$$\|v_h\|^2 + \|\nabla_h v_h\|^2 \leq \|\nabla_h v_h\|^2 + \sum_{F \in \mathcal{F}_h} h^{-1}_F \|v_h\|^2_F + \sup_{m \in \mathbb{R}} \left( \int_{\mathcal{T}} \gamma(v_h) \cdot \gamma(m) \right)^2$$

$$\leq \|\nabla_h v_h\|^2 + \sum_{F \in \mathcal{F}_h} h^{-1}_F \|v_h\|^2_F + \sum_{F \in \mathcal{F}_h} \|v_h\|^2_F .$$  \hspace{1cm} (70)

For an interface $F \in \mathcal{F}_h \cap \mathcal{F}_h^b$, we have introduced the jump $[v_h]_F := v_T - v_T^b$. Thus, using the triangle inequality, we get $\|v_h\|^2_F \leq \|v_T - v_T^b\|^2_F + \|v_F - v_T\|^2_F$. For a boundary face $F \in \mathcal{F}_h^b$ such that $F \in \mathcal{F}_h \cap \mathcal{F}_h^b$ for some $T \in \mathcal{T}_h$ we have, on the other hand, $\|v_h\|^2_F = \|v_T - v_T\|^2_F$ since $v_F \equiv 0$ (cf. (20)). Using these relations in the right-hand side of (70) and rearranging the sums leads to

$$\|v_h\|^2 + \|\nabla_h v_h\|^2 \leq \sum_{T \in \mathcal{T}_h} \left( \|\nabla_h v_T\|^2_T + \sum_{F \in \mathcal{F}_h} h^{-1}_F \|v_F - v_T\|^2_F \right) + h \sum_{F \in \mathcal{F}_h^b} h^{-1}_F \|v_F - v_T\|^2_F$$

$$\leq \max\{1, d_\Omega\} \sum_{T \in \mathcal{T}_h} \left( \|\nabla_h v_T\|^2_T + \sum_{F \in \mathcal{F}_h} h^{-1}_F \|v_F - v_T\|^2_F \right),$$

where $d_\Omega$ denotes the diameter of $\Omega$. Owing to the definition (14) of the discrete strain seminorm, the latter yields the assertion.  \[ \square \]
