Analytic Hadamard states, Calderón projectors and Wick rotation near analytic Cauchy surfaces

Christian GÉRARD & Michał WROCHNA

ABSTRACT. We consider the Klein-Gordon equation on analytic spacetimes with an analytic Cauchy surface. In this setting, we prove the existence of pure analytic Hadamard states. The proof is based on considering an elliptic operator obtained by Wick rotating the Klein-Gordon operator in a neighborhood of a Cauchy hypersurface. The Cauchy data of Hadamard two-point functions are constructed as Calderón projectors (suitably generalized if the hypersurface is non-compact) for the elliptic operator.

1. INTRODUCTION & SUMMARY

1.1. Analytic Hadamard condition. In Quantum Field Theory on curved spacetimes, the *Hadamard condition* plays a key role as a mean to select physically relevant states and as an ingredient in the renormalization of a priori ill-defined products of quantum fields. In the setup of the linear Klein-Gordon equation, it amounts to a condition on the C^∞ wave front set of certain bi-solutions: the field's *two-point functions*.

Presently, many techniques to construct two-point functions satisfying the Hadamard condition are available. This includes abstract proofs of existence on arbitrary globally hyperbolic spacetimes [FNW, GW1], as well as more explicit constructions on classes of spacetimes with good behavior at spatial infinity [Ju, JS, GW1, GOW] and various other additional assumptions [Ol, BT]. Furthermore, other strategies have been developed for spacetimes with specific asymptotic structures, in which case it is possible to have distinguished candidates for Hadamard two-point functions [Mo, DMP1, DMP2, BJ, Sa2, GW3, VW], or to use global arguments [BF, VW] (cf. [GHV, GW4] for the related problem of constructing Feynman generalized inverses).

The situation is however dramatically different if one requires an analogue of the Hadamard condition with the C^∞ wave front set replaced by the *analytic wave front set* WF_a (see Def. 5.1), assuming that the spacetime is analytic. The *analytic Hadamard condition* was introduced by Strohmaier, Verch and Wollenberg, who have shown that whenever satisfied, it has remarkable consequences for the quantum field theory, as it implies the *Reeh-Schlieder property* [SVW]. This means that any vector in the Hilbert space can be approximated arbitrarily well by acting on the vacuum with operations performed in any prescribed open region (see Subsect. 2.4). Unfortunately, only few examples of two-point functions were shown to satisfy

Key words and phrases. Quantum Field Theory on curved spacetimes, Hadamard states, Calderón projector, Wick rotation.

the analytic Hadamard condition, namely the *ground* and *KMS states* on analytic stationary spacetimes with an analytic Killing vector field [SVW]. Moreover, the methods developed for the C^∞ case do not seem to be directly useful in that respect, outside of the stationary case, as they rely on ingredients specific to the C^∞ setting, such as spacetime deformation or variants of Hörmander's pseudodifferential calculus.

In the present work we fill this gap by providing a construction of analytic Hadamard two-point functions without assuming any symmetries of the spacetime. In the language of algebraic QFT, we construct *analytic Hadamard* (quasi-free) *states* (see Sect. 2.1–2.3 for the relevant definitions), which are more precisely *pure* ones (see Prop. 2.1 for a criterion formulated in terms of two-point functions). In this terminology, the main result can be stated as follows.

Let us recall that a hypersurface in a spacetime is *Cauchy* if it is intersected by every inextendible, causal (i.e. non-spacelike) curve exactly once.

Theorem 1.1. *Let (M, g) be an analytic spacetime with an analytic space-like Cauchy hypersurface. Suppose P is a differential operator of the form $P = -\square_g + V$, where $V : M \rightarrow \mathbb{R}$ is real analytic. Then there exists a pure analytic Hadamard state for P .*

1.2. Outline of proof. The main steps in the proof of Thm. 1.1 can be summarized as follows.

First, we show that the problem can be reduced to a situation where the spacetime is replaced by a neighborhood of a Cauchy surface Σ and the Lorentzian metric is of the form $-dt^2 + h_t(y)dy^2$. Moreover, we argue that $t \mapsto h_t$ can be assumed without loss of generality to be a real analytic family of metrics on Σ such that h_0 is complete. In this setup, the Klein-Gordon operator reads

$$P = \partial_t^2 + r(t, y)\partial_t + a(t, y, \partial_y),$$

where a is an elliptic differential operator of order 2.

Next, we perform the *Wick rotation* in t , i.e. by means of the substitution $t =: is$ we get an elliptic operator

$$K = -\partial_s^2 - ir(is, y)\partial_s + a(is, y, \partial_y)$$

defined on a neighborhood of $\{0\} \times \Sigma$. After possibly choosing a smaller neighborhood Ω , we associate to K a closed operator K_Ω by imposing Dirichlet boundary conditions on the boundary of Ω and we prove that K_Ω is invertible.

The construction is then an adaptation of a recent idea from [Gé], which consists in considering the *Calderón projectors* of K_Ω on the hypersurface $\{s = 0\}$. While the Calderón projectors belong to the standard toolbox of elliptic problems on manifolds with boundary (see e.g. [Gr, H3]), their use in QFT in [Gé] and in the present work is new. In addition to what can be found in the literature, here we also need to cope with issues related to the fact that K is in general not formally self-adjoint, and the hypersurface $\{s = 0\}$ might not be compact.

The rough idea is that for solutions of $K_\Omega u = 0$ in $\Omega^\pm = \{\Omega \cap \pm s > 0\}$, one can consider their Cauchy data

$$\gamma^\pm u = \begin{pmatrix} u|_\Sigma \\ -\partial_s u|_\Sigma \end{pmatrix},$$

where the trace on Σ is understood as a limit from $\Omega^\pm$.

Supposing for the moment that Σ is compact, the space of all such data can be characterized as the range of a projector $C_\Omega^\pm$. It is well-known that these projectors can be constructed using the formula

$$(1.1) \quad C_\Omega^\pm := \mp \gamma^\pm K_\Omega^{-1} \gamma^* S,$$

where S is a suitable 2×2 matrix of multiplication operators and

$$\gamma^* f = \delta(s) \otimes f_0 + \delta'(s) \otimes f_1, \quad f = \begin{pmatrix} f_0 \\ f_1 \end{pmatrix} \in C_c^\infty(\Sigma)^2.$$

Now, while $C_\Omega^\pm$ are constructed in the Wick-rotated elliptic setting, we use them as the Cauchy data of bi-solutions $\Lambda^\pm$ for the original hyperbolic problem. The key property which allows us to conclude the analytic Hadamard condition for $\Lambda^\pm$ is:

$$(1.2) \quad \forall f \in \mathcal{E}'(\Sigma)^2, \quad \text{WF}_a(U_\Sigma C_\Omega^\pm f) \subset \{\pm \tau \geq 0\},$$

where τ is the covariable dual to t and $U_\Sigma C_\Omega^\pm f$ is the unique solution of $Pu = 0$ with Cauchy data on Σ equal to $C_\Omega^\pm f$. The general strategy in the proof of (1.2) is based on ideas due to Pierre Schapira and is to a large degree a special case of the analysis in [Sch]. In our setting, the main step, (forgetting the space variables $x \in \Sigma$), consists in constructing the analytic continuation of the function $(-K_\Omega^{-1} \gamma^* S f)(s)$, and proving that the so-obtained holomorphic function has a boundary value which is precisely the distribution $(U_\Sigma C_\Omega^+ f)(t)$. Using propagation of singularities theorems we show that it is sufficient to do so locally, and we give such local construction basing on theorems on representations of distributions as sums of boundary values of holomorphic functions.

To show that the pair of operators $C_\Omega^\pm$ can be used to define a state, one needs to check that it satisfies the identity (well-known in the compact case)

$$(1.3) \quad C_\Omega^+ + C_\Omega^- = \mathbb{1},$$

and a positivity condition (see Thm. 4.5 for the precise statement). It turns out that the latter can be proved by an argument reminiscent of *reflection positivity* in Euclidean QFT.

Finally, still supposing that Σ is compact, the purity statement in Thm. 1.1 is merely a direct corollary of the operators $C_\Omega^\pm$ being projections.

The case of Σ non-compact is technically more involved. We show that formula (1.1) still makes sense without the need of making extra assumptions on the geometry at spatial infinity, and (1.2)-(1.3) remain valid. However, purity is more subtle because it is not a priori clear if there is a suitable space on which $C_\Omega^\pm$ are projections. Using an approximation argument we show instead that $C_\Omega^\pm$ satisfy a weaker condition, which implies the purity statement nevertheless. The approximation argument is also used in the proof of the positivity properties of $C_\Omega^\pm$ in the non-compact case.

1.3. Discussion and outlook. Once the Wick rotation is performed on the geometric level and the (sufficiently small) neighborhood Ω of $\{0\} \times \Sigma$ is chosen, our construction provides a canonical choice of analytic Hadamard two-point functions. Thus, in situations where a Cauchy surface is chosen and where the size of Ω is immaterial or under control, the construction assigns unambiguously a pair of Hadamard two-point functions to the space-time. While that assignment is not expected to be locally covariant in the sense of [BFV], it could be of practical interest in the study of semi-classical Einstein equations nevertheless.

An interesting issue is the relation of the present work to the construction of Hadamard states by pseudo-differential techniques in [Ju, JS, GW1, GOW]. We expect that an alternative proof of (1.2) could be given using a ‘Wick-rotated’ version of the parametrix in [GOW]. Here, we chose not to use such arguments in order to avoid any assumptions on the geometry of the Cauchy surface at infinity. It is however worth stressing that the present work was triggered by the observation¹ that the parametrix construction from [GOW] is reminiscent of parametrices for Calderón projectors in elliptic problems.

The construction in the present paper is also expected to preserve some symmetries that are not directly under control in techniques developed for the general C^∞ case [FNW, GW1]. This could be of particular merit e.g. in gauge theories.

It is worth pointing out that if the spacetime has special symmetries, an analogous construction with different boundary conditions can be particularly useful. This is for instance the case on spacetimes with a bifurcate Killing horizon, where a Calderón projector corresponding to periodic boundary conditions can be used to construct the Hartle-Hawking-Israel state [Gé].

An interesting perspective would be the extension of the present construction to setups where the spacetime has a boundary. This would require a good understanding of Calderón projectors on manifolds with corners.

1.4. Plan of the paper. The main part of the paper is structured as follows.

In Sect. 2 we review standard definitions and results on Hadamard states and analytic Hadamard states. In Sect. 3 we perform the Wick rotation and study various properties of the elliptic operator K_Ω . The associated (generalized) Calderón projectors $C_\Omega^\pm$ are defined and analyzed in Sect. 4. We prove in particular that they can be used to define *pure* quasi-free states. We also briefly discuss the special case of an ultra-static metric. Sect. 5 is devoted to the proof of the analytic Hadamard condition; it includes an introduction to the analytic wave front set and its basic properties. An auxiliary lemma is deferred to the appendix.

1.5. Notation. Throughout the paper we adopt the following notations and conventions.

- We write $A \Subset B$ if A is relatively compact in B .

¹This observation was kindly communicated to us by Francis Nier, to whom we are very grateful.

- If X, Y are sets and $f : X \rightarrow Y$ we write $f : X \xrightarrow{\sim} Y$ if f is bijective. If X, Y are equipped with topologies, we write $f : X \rightarrow Y$ if the map is continuous, and $f : X \xrightarrow{\sim} Y$ if it is a homeomorphism.
- The domain of a closed, densely defined operator a will be denoted by $\text{Dom } a$.

2. QUANTUM KLEIN-GORDON FIELDS

2.1. Klein-Gordon fields. In this section we review classical results about quasi-free states for free Klein-Gordon quantum fields on a globally hyperbolic spacetime, see e.g. [BGP, DG, KM, HW] for textbook accounts and recent reviews. We will use the complex formalism, based on charged fields.

2.1.1. Bosonic quasi-free states. Let $\mathcal{V}$ be a complex vector space, $\mathcal{V}^*$ its anti-dual and let us denote by $L_h(\mathcal{V}, \mathcal{V}^*)$ the space of hermitian sesquilinear forms on $\mathcal{V}$. We denote by $\bar{v}_1 \cdot q v_2$ the evaluation of $q \in L(\mathcal{V}, \mathcal{V}^*)$ on $v_1, v_2 \in \mathcal{V}$.

A pair $(\mathcal{V}, q)$ consisting of a complex vector space $\mathcal{V}$ and a non-degenerate hermitian form q on $\mathcal{V}$ will be called a *phase space*. Denoting by $\mathcal{V}_{\mathbb{R}}$ the real form of $\mathcal{V}$, i.e. $\mathcal{V}$ considered as a real vector space, $(\mathcal{V}_{\mathbb{R}}, \text{Im } q)$ is a real symplectic space.

The *CCR $*$ -algebra* $\text{CCR}(\mathcal{V}, q)$ is the abstract $*$ -algebra generated by $\mathbb{1}$ and elements $\psi(v), \psi^*(v)$ for $v \in \mathcal{V}$, subject to relations:

$$\begin{aligned} \psi(v + \lambda w) &= \psi(v) + \bar{\lambda} \psi(w), \\ \psi^*(v + \lambda w) &= \psi^*(v) + \lambda \psi^*(w), \\ [\psi(v), \psi(w)] &= [\psi^*(v), \psi^*(w)] = 0, \quad [\psi(v), \psi^*(w)] = \bar{v} q w \mathbb{1}, \\ \psi(v)^* &= \psi^*(v), \quad \lambda \in \mathbb{C}, v, w \in \mathcal{V}. \end{aligned}$$

Equivalently, $\text{CCR}(\mathcal{V}, q)$ is generated by $\mathbb{1}$ and $\phi(v)$ for $v \in \mathcal{V}$, where the (abstract) *real fields* $\phi(v)$ are defined by

$$\phi(v) := \frac{1}{\sqrt{2}}(\psi(v) + \psi^*(v)),$$

and

$$[\phi(v_1), \phi(v_2)] = i v_1 \cdot \text{Im } q v_2, \quad v_1, v_2 \in \mathcal{V}.$$

A (gauge invariant) quasi-free state ω on $\text{CCR}(\mathcal{V}, q)$ is entirely characterized by its *complex covariances* $\Lambda^{\pm} \in L_h(\mathcal{V}, \mathcal{V}^*)$ defined by

$$(2.1) \quad \bar{v} \cdot \Lambda^+ w := \omega(\psi(v) \psi^*(w)), \quad \bar{v} \cdot \Lambda^- w := \omega(\psi^*(w) \psi(v)), \quad v, w \in \mathcal{V},$$

since gauge invariance implies that

$$\omega(\psi(v) \psi(w)) = \omega(\psi^*(v) \psi^*(w)) = 0, \quad v, w \in \mathcal{V}.$$

Note that $\Lambda^{\pm} \geq 0$ and $\Lambda^+ - \Lambda^- = q$ by the canonical commutation relations. Conversely if $\Lambda^{\pm}$ are Hermitian forms on $\mathcal{V}$ such that

$$(2.2) \quad \Lambda^+ - \Lambda^- = q, \quad \Lambda^{\pm} \geq 0,$$

then there is a unique (gauge invariant) quasi-free state ω such that (2.1) holds, see e.g. [DG, Sect. 17.1]. One can associate to ω the pair of operators $c^{\pm} \in L(\mathcal{V})$:

$$(2.3) \quad c^{\pm} := \pm q^{-1} \circ \Lambda^{\pm}.$$

The properties (2.2) become then:

$$(2.4) \quad c^+ + c^- = \mathbb{1}, \quad c^{\pm*}q = qc^{\pm}, \quad \pm qc^{\pm} \geq 0.$$

In the real formalism one has:

$$\omega(\phi(v_1)\phi(v_2)) = v_1 \cdot \eta v_2 + \frac{i}{2} v_1 \operatorname{Im} q v_2,$$

where the symmetric form $\eta \in L_s(\mathcal{V}, \mathcal{V}^\#)$ is called the *real covariance* of ω .

We recall a well-known characterization of *pure states* (see e.g. [KW] in the real case and [GOW, Prop. 7.1] for another equivalent characterization).

Proposition 2.1. *The state ω with covariances $\Lambda^\pm$ is pure iff:*

$$(2.5) \quad \bar{v}_1 \cdot (\Lambda^+ + \Lambda^-) v_1 = \sup_{v_2 \in \mathcal{V}, v_2 \neq 0} \frac{|\bar{v}_1 \cdot q v_2|^2}{\bar{v}_2 \cdot (\Lambda^+ + \Lambda^-) v_2}, \quad \forall v_1 \in \mathcal{V}.$$

Proof. Consider $\mathcal{V}$ as a real vector space, equipped with the symplectic form $\sigma = \operatorname{Im} q$. Then from [GW1, Subsect. 2.3] we know that the real covariance of ω is $\eta = \frac{1}{2} \operatorname{Re}(\Lambda^+ + \Lambda^-)$. From [KW] we know that ω is a pure state iff

$$v_1 \cdot \eta v_1 = \frac{1}{4} \sup_{v_2 \neq 0} \frac{|v_1 \cdot \operatorname{Im} q v_2|^2}{v_2 \cdot \eta v_2}.$$

Using that $\eta = \frac{1}{2} \operatorname{Re}(\Lambda^+ + \Lambda^-)$ and that q is sesquilinear, this is equivalent to (2.5). $\square$

2.1.2. Klein-Gordon fields. We adopt the convention that a *spacetime* is a Hausdorff, paracompact, connected, time orientable smooth Lorentzian manifold equipped with a time orientation.

Let (M, g) be a globally hyperbolic spacetime, i.e. a spacetime possessing a smooth spacelike Cauchy hypersurface, and let

$$P = -\nabla^a \nabla_a + V(x), \quad V \in C^\infty(M, \mathbb{R})$$

be a Klein-Gordon operator on (M, g) .

We denote by $G_{\text{ret/adv}}$ the retarded/advanced inverses for P (see e.g. [BGP]) and by $G := G_{\text{ret}} - G_{\text{adv}}$ the Pauli-Jordan commutator. We set

$$(2.6) \quad (u|v)_M := \int_M \bar{u} v \, d\operatorname{vol}_g, \quad u, v \in C_c^\infty(M),$$

and we will use $(\cdot|\cdot)_M$ to identify sesquilinear forms on $C_c^\infty(M)$ with linear operators from $C_c^\infty(M)$ to $C^\infty(M)$. We set:

$$(2.7) \quad \mathcal{V} := \frac{C_c^\infty(M)}{PC_c^\infty(M)}, \quad [\bar{u}] \cdot Q[v] := i(u|Gv)_M.$$

It is well-known that $(\mathcal{V}, Q)$ is a phase space.

Let now Σ be a smooth spacelike Cauchy hypersurface for (M, g) and $\mathcal{V}_\Sigma = C_c^\infty(\Sigma; \mathbb{C}^2)$. We equip $\mathcal{V}_\Sigma$ with the scalar product

$$(2.8) \quad (f|g)_\Sigma := \int_\Sigma \bar{f}_0 g_0 + \bar{f}_1 g_1 \, d\sigma_\Sigma,$$

and again, we use $(\cdot|\cdot)_\Sigma$ to identify sesquilinear forms on $C_c^\infty(\Sigma; \mathbb{C}^2)$ with linear operators from $C_c^\infty(\Sigma; \mathbb{C}^2)$ to $C^\infty(\Sigma; \mathbb{C}^2)$. Let us set

$$\rho_\Sigma u := \begin{pmatrix} u|_\Sigma \\ i^{-1} \partial_n u|_\Sigma \end{pmatrix},$$

where n is the future unit normal to Σ and:

$$(2.9) \quad q_\Sigma = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}$$

It is well known that the map:

$$\rho_\Sigma G : (\mathcal{V}, Q) \rightarrow (\mathcal{V}_\Sigma, q_\Sigma)$$

is pseudo-unitary, i.e.

$$\overline{\rho_\Sigma G u} \cdot q_\Sigma \rho_\Sigma G v = \overline{[u]} \cdot Q[v], \quad u, v \in C_c^\infty(M).$$

One can use equivalently either of the two above phase spaces. The CCR $*$ -algebra associated to either $(\mathcal{V}, Q)$ or $(\mathcal{V}_\Sigma, q_\Sigma)$ will be simply denoted by $\text{CCR}(P)$.

2.1.3. Spacetime two-point functions. We will use for the moment the phase space $(\mathcal{V}, Q)$ defined in (2.7). Let us introduce the conditions:

$$(2.10) \quad \begin{aligned} i) \quad & \Lambda^\pm : C_c^\infty(M) \rightarrow C^\infty(M), \\ ii) \quad & \Lambda^\pm \geq 0 \text{ for } (\cdot|\cdot)_M \text{ on } C_c^\infty(M), \\ iii) \quad & \Lambda^+ - \Lambda^- = iG, \\ iv) \quad & P\Lambda^\pm = \Lambda^\pm P = 0, \\ v) \quad & (u|\Lambda^\pm u)_M \geq 0, \quad \forall u \in C_c^\infty(M). \end{aligned}$$

As explained above, we set with a slight abuse of notation:

$$\overline{[u]} \cdot \Lambda^\pm[v] := (u|\Lambda^\pm v)_M, \quad [u], [v] \in \frac{C_c^\infty(M)}{PC_c^\infty(M)}.$$

If (2.10) hold, then $\Lambda^\pm$ define a pair of complex covariances on the phase space $(\mathcal{V}, Q)$ defined in (2.7), hence define a unique quasi-free state on $\text{CCR}(P)$.

Definition 2.2. A pair of maps $\Lambda^\pm : C_c^\infty(M) \rightarrow C^\infty(M)$ satisfying (2.10) will be called a pair of spacetime two-point functions.

2.1.4. Cauchy surface two-point functions. We will need a version of two-point functions acting on Cauchy data for P instead of test functions on M .

Let us introduce the assumptions:

$$(2.11) \quad \begin{aligned} i) \quad & \lambda_\Sigma^\pm : C_c^\infty(\Sigma; \mathbb{C}^2) \rightarrow C^\infty(\Sigma; \mathbb{C}^2), \\ ii) \quad & \lambda_\Sigma^\pm \geq 0 \text{ for } (\cdot|\cdot)_\Sigma, \\ iii) \quad & \lambda_\Sigma^+ - \lambda_\Sigma^- = q_\Sigma. \end{aligned}$$

Definition 2.3. A pair of maps $\lambda_\Sigma^\pm$ satisfying (2.11) will be called a pair of Cauchy surface two-point functions.

The following proposition is shown in [GW2] in a more general situation.

Proposition 2.4. *The maps:*

$$\lambda_{\Sigma}^{\pm} \mapsto \Lambda^{\pm} := (\rho_{\Sigma} G)^* \lambda_{\Sigma}^{\pm} (\rho_{\Sigma} G),$$

$$\Lambda^{\pm} \mapsto \lambda_{\Sigma}^{\pm} := (\rho_{\Sigma}^* q_{\Sigma})^* \Lambda^{\pm} (\rho_{\Sigma}^* q_{\Sigma})$$

are bijective and inverse from one another. Furthermore, $\lambda_{\Sigma}^{\pm}$ are Cauchy surface two-point functions iff $\Lambda^{\pm}$ are spacetime two-point functions.

2.2. The Hadamard condition. We now recall the celebrated *Hadamard condition* in its microlocal formulation.

We start by recalling some standard notation.

- For $x \in M$ we denote by $V_{x\pm} \subset T_x M$ the future/past solid lightcones and by $V_{x\pm}^* \subset T_x^* M$ the dual cones $V_{x\pm}^* = \{\xi \in T_x^* M : \xi \cdot v > 0, \forall v \in V_{x\pm}, v \neq 0\}$. We write

$$\xi \triangleright 0 \text{ (resp. } \xi \triangleleft 0) \text{ if } \xi \in V_{x+}^* \text{ (resp. } V_{x-}^*).$$

- We denote by o the zero section of T^*M .
- For $X = (x, \xi) \in T^*M \setminus o$ we denote by $p(X) = \xi \cdot g^{-1}(x)\xi$ the principal symbol of P and by $\mathcal{N} = p^{-1}(0) \cap T^*M \setminus o$ the characteristic manifold of P . If H_p is the Hamiltonian vector field of p , integral curves of H_p in $\mathcal{N}$ are called *bicharacteristics*. $\mathcal{N}$ splits into the *upper/lower energy shells*

$$\mathcal{N} = \mathcal{N}^+ \cup \mathcal{N}^-, \quad \mathcal{N}^{\pm} = \mathcal{N} \cap \{\pm \xi \triangleright 0\}.$$

- If $\Gamma \subset T^*M \times T^*M$ we set

$$\Gamma' = \{((x_1, \xi_1), (x_2, \xi_2)) : ((x_1, \xi_1), (x_2, -\xi_2)) \in \Gamma\}.$$

- If $u \in \mathcal{D}'(M)$, the *wave front set* of u is denoted by $\text{WF}(u)$ and is a closed conic subset of $T^*M \setminus o$.

By the Schwartz kernel theorem, we can identify $\Lambda^{\pm}$ with a pair of distributions $\Lambda^{\pm}(x, x') \in \mathcal{D}'(M \times M)$. One is especially interested in the subclass of *Hadamard states*, which are subject to a condition on the *wave front set* of $\Lambda^{\pm}(x, x')$.

Definition 2.5. *A quasi-free state ω on $\text{CCR}(P)$ is a Hadamard state if its covariances $\Lambda^{\pm}$ satisfy $\Lambda^{\pm} : C_c^{\infty}(M) \rightarrow C^{\infty}(M)$ and*

$$(2.12) \quad \text{WF}(\Lambda^{\pm})' \subset \mathcal{N}^{\pm} \times \mathcal{N}^{\pm}.$$

This form of the Hadamard condition is taken from [SV, Ho]. The original formulation in terms of wave front sets is due to Radzikowski [R1], who showed its equivalence with older definitions [KW].

A fundamental result is the following existence theorem of Hadamard states, which was proved by Fulling, Narcovich and Wald in [FNW]:

Theorem 2.6 ([FNW]). *Let P be a Klein-Gordon operator on a globally hyperbolic spacetime (M, g) . Then there exist pure, quasi-free Hadamard states for P .*

The proof of this result proceeds by constructing an interpolating metric $\tilde{g}$ and a Klein-Gordon operator $\tilde{P}$ which equal g, P in the far future of some Cauchy surface Σ and equal $g_{\text{us}}, P_{\text{us}}$ in the far past of Σ , where g_{us} is some ultrastatic metric and P_{us} is the associated Klein-Gordon operator with a

constant mass. Transporting the vacuum state for g_{us} to the far future of Σ by the evolution of $\tilde{P}$ yields a state for P . The Hadamard condition on g is then concluded from the Hadamard property of the vacuum state for g_{us} using the propagation of singularities theorem and the time-slice property of Klein-Gordon fields.

2.3. The analytic Hadamard condition. In [SVW], Strohmaier, Verch and Wollenberg introduced the notion of *analytic Hadamard states*, obtained from Def. 2.5 by replacing the C^∞ wave front set WF by the *analytic wave front set* WF_a .

The definition of the analytic wave front set $\text{WF}_a(u)$ of a distribution $u \in \mathcal{D}'(N)$, for N a real analytic manifold, will be recalled in Subsect. 5.2.

The basic results of microlocal analysis, such as microlocal ellipticity or propagation of singularities theorems, require to consider differential operators with analytic coefficients when one wants to study for example the analytic wave front set of solutions.

Therefore the notion of analytic Hadamard states is restricted to *analytic spacetimes* (M, g) , i.e. real analytic manifolds M equipped with a real analytic Lorentzian metric g . The Klein-Gordon operator P is now

$$(2.13) \quad P = -\nabla^a \nabla_a + V(x), \text{ where } V : M \rightarrow \mathbb{R} \text{ is real analytic.}$$

We will call a Klein-Gordon operator as above an *analytic Klein-Gordon operator*.

Definition 2.7. A quasi-free state on $\text{CCR}(P)$ is an analytic Hadamard state if its spacetime covariances $\Lambda^\pm$ satisfy

$$(2.14) \quad \text{WF}_a(\Lambda^\pm)' \subset \mathcal{N}^\pm \times \mathcal{N}^\pm.$$

In [SVW] the analytic Hadamard condition is also defined for more general states on $\text{CCR}(P)$ by extending the microlocal spectrum condition of Brunetti, Fredenhagen and Köhler [BFK] on the n -point functions to the analytic case.

It is shown in [SVW, Prop. 6.2] that for quasi-free states, the analytic microlocal spectrum condition is equivalent to the following real version of (2.14).

Let $\phi(u) = \frac{1}{\sqrt{2}}(\psi(u) + \psi^*(u))$ for $u \in C_c^\infty(M)$ real, and let $\omega_2 \in \mathcal{D}'(M \times M)$ be the (real) two-point function of ω defined by

$$\omega(\phi(u)\phi(v)) = \langle \omega_2, u \otimes v \rangle, \quad u, v \in C_c^\infty(M; \mathbb{R}).$$

Then the C^∞ (resp. analytic) Hadamard condition is equivalent to:

$$(2.15) \quad \text{WF}(\omega_2)' \text{ (resp. } \text{WF}_a(\omega_2)') \subset \mathcal{N}^+ \times \mathcal{N}^+.$$

In [GW1, Remark 3.3] it is shown that for the C^∞ wave front set (2.15) is equivalent to (2.12). The same argument is valid for the analytic wave front set.

It has been shown by Radzikowski [R1] that the covariances of any two Hadamard states coincide modulo a smooth kernel. The same is true for analytic Hadamard states:

Proposition 2.8. Let $\omega, \tilde{\omega}$ be two analytic Hadamard states for some analytic Klein-Gordon operator P . Then $\Lambda^\pm - \tilde{\Lambda}^\pm$ have analytic kernels.

Proof. Let $R^\pm = \Lambda^\pm - \tilde{\Lambda}^\pm$. Since $\Lambda^+ - \Lambda^- = \tilde{\Lambda}^+ - \tilde{\Lambda}^- = iG$, we have $R^+ = -R^-$. On the other hand from (2.14) we have $\text{WF}_a(R^\pm)' \subset \mathcal{N}^\pm \times \mathcal{N}^\pm$ hence $\text{WF}_a(R^+)' \cap \text{WF}_a(R^-)' = \emptyset$. Since $R^- = -R^+$ this implies that $\text{WF}_a(R^\pm)' = \emptyset$ hence $R^\pm$ have analytic kernels. $\square$

2.4. The Reeh-Schlieder property. In [SVW], Strohmaier, Verch and Wollenberg proved an important consequence of the analytic Hadamard condition.

Theorem 2.9 ([SVW]). *An analytic Hadamard state on $\text{CCR}(P)$ satisfies the Reeh-Schlieder property.*

We first recall how the Reeh-Schlieder property is defined. If ω is a state on $\text{CCR}(P)$ we denote by $(\mathcal{H}_\omega, \pi_\omega, \Omega_\omega)$ the GNS triple associated to ω .

Definition 2.10. *A state ω on $\text{CCR}(P)$ satisfies the Reeh-Schlieder property if for any open set $U \subset M$ the space*

$$\text{Vect}\left\{\pi_\omega\left(\prod_1^p \psi^*(u_i) \prod_1^q \psi(v_j)\right)\Omega_\omega : p, q \in \mathbb{N}, u_i, v_j \in C_c^\infty(U)\right\}$$

is dense in $\mathcal{H}_\omega$.

The proof of Thm. 2.9 in [SVW] relies on two ingredients: the first is the use of wave front set for Hilbert space valued distributions. The second is the fact that the analytic wave front set $\text{WF}_a(u)$ of $u \in \mathcal{D}'(M)$ has deep relations with the support $\text{supp } u$. An example of such a relation is the *Kashiwara-Kawai theorem*, which we state below for illustration, and which plays a key role in [SVW].

If $F \subset M$ is a closed set, the *normal set* $N(F) \subset T^*M \setminus o$ is the set of (x^0, ξ^0) such that $x^0 \in F$, $\xi^0 \neq 0$, and there exists a real function $f \in C^2(M)$ such that $df(x^0) = \xi^0$ or $df(x^0) = -\xi^0$ and $F \subset \{x : f(x) \leq f(x^0)\}$. Note that $N(F) \subset T_{\partial F}^*M$.

The *Kashiwara-Kawai theorem* (see e.g. [H2, Thm. 8.5.6']) states that

$$(2.16) \quad N(\text{supp } u) \subset \text{WF}_a(u) \quad \forall u \in \mathcal{D}'(M).$$

2.5. Existence of analytic Hadamard states on analytic spacetimes.

It is not an easy task to construct analytic Hadamard states. The main problem is that the Fulling-Narowich-Wald deformation argument [FNW] used to prove Thm. 2.6 does not apply anymore as the interpolating metric $\tilde{g}$ is not real analytic (though at least a weaker form of the Reeh-Schlieder property can be obtained, and an abstract existence argument can be given for states satisfying the full Reeh-Schlieder property, see [Sa1]).

The only examples of analytic Hadamard states known so far are the *vacua* (ground states) and *KMS states* on analytic, stationary spacetimes with an analytic Killing vector field, see [SVW, Thm. 6.3].

Our main result, Thm. 1.1, provides a general existence proof for any analytic Klein-Gordon operator P on an analytic spacetime with an analytic, spacelike Cauchy hypersurface.

Before introducing the main new ingredients of our construction, let us recall two standard facts which are useful to construct Hadamard states, both in the C^∞ and analytic case, the first one relying on propagation of singularities and the second on conformal transformations.

Proposition 2.11. *Let (M, g) be a globally hyperbolic analytic spacetime, P an analytic Klein-Gordon operator on (M, g) , ω a quasi-free state for P and Σ a Cauchy hypersurface for (M, g) .*

If its covariances $\Lambda^\pm$ satisfy the analytic Hadamard condition (2.14) over some neighborhood U of Σ then they satisfy (2.14) everywhere.

Proof. Let ϕ_s , $s \in \mathbb{R}$ be the Hamiltonian flow of p . By (2.10) *iv*), microlocal ellipticity and propagation of singularities in the analytic case (see [Kw, Thm. 3.3'] or [H4, Thm. 7.1]), we know that if $(X_1, X_2) \in \text{WF}_a(\Lambda^\pm)'$, then $X_1, X_2 \in \mathcal{N}$ and $(\phi_{s_1}(X_1), \phi_{s_2}(X_2)) \in \text{WF}_a(\Lambda^\pm)'$ for all $s_1, s_2 \in \mathbb{R}$. Since Σ is a Cauchy hypersurface, there exists s_1, s_2 such that $\phi_{s_i}(X_i) \in T^*U$, hence $\phi_{s_i}(X_i) \in \mathcal{N}^\pm$, hence $X_i \in \mathcal{N}^\pm$. $\square$

Proposition 2.12. *Let (M, g) be a globally hyperbolic analytic spacetime with a Cauchy hypersurface Σ .*

Suppose that there exists a neighborhood U of Σ in M and an analytic function $c : U \rightarrow]0, +\infty[$ such that any analytic Klein-Gordon operator on (U, c^2g) has a pure analytic Hadamard state. Then any analytic Klein-Gordon operator on (M, g) has a pure analytic Hadamard state.

Proof. We write P as $-\square_g + \frac{n-2}{4(n-1)}R_g + W$ with W real analytic. By conformal invariance of $-\square_g + \frac{n-2}{4(n-1)}R_g$, setting $\tilde{g} = c^2g$ we have:

$$\tilde{P} := c^{-n/2-1}Pc^{n/2-1} = -\square_{\tilde{g}} + \frac{n-2}{4(n-1)}R_{\tilde{g}} + \tilde{W},$$

where $\tilde{W} = c^{-2}W$. If $\tilde{G}$ is the Pauli-Jordan commutator for $\tilde{P}$ we have $G = c^{n/2-1}\tilde{G}c^{-n/2-1}$. It follows that if $\tilde{\Lambda}^\pm$ are the covariances of some quasi-free state $\tilde{\omega}$ for $\tilde{P}$, then $\Lambda^\pm = c^{n/2-1}\tilde{\Lambda}^\pm c^{-n/2-1}$ are the covariances of some quasi-free state ω for P .

If $\tilde{\omega}$ is a pure state then so is ω . Indeed, denoting by $(\tilde{\mathcal{V}}, \tilde{Q})$ the classical phase space for $\tilde{P}$, the map

$$T : \tilde{\mathcal{V}} \ni [\tilde{u}] \mapsto [c^{n/2+1}\tilde{u}] \in \mathcal{V}$$

is pseudo-unitary from $(\tilde{\mathcal{V}}, \tilde{Q})$ to $(\mathcal{V}, Q)$, and ω is simply the pushforward of $\tilde{\omega}$ by T .

If $\tilde{\omega}$ is an analytic Hadamard state for $\tilde{P}$, $\tilde{\Lambda}^\pm$ satisfy (2.14) over U , and so do $\Lambda^\pm$ since c is analytic. By Prop. 2.11 $\Lambda^\pm$ satisfy (2.14) over M , hence ω is an analytic Hadamard state. $\square$

3. WICK ROTATION ON ANALYTIC SPACETIMES

In this section we perform the Wick rotation in Gaussian normal coordinates. If Σ is a spacelike Cauchy hypersurface in (M, g) , the Klein-Gordon operator P is written as

$$P = \partial_t^2 + r(t, y)\partial_t + a(t, y, \partial_y),$$

if (t, y) are Gaussian normal coordinates respective to Σ . By analyticity one can perform the *Wick rotation* $t =: is$ near $s = 0$ and consider the *Wick rotated operator*

$$K = -\partial_s^2 - ir(is, y)\partial_s + a(is, y, \partial_y),$$

which is an elliptic differential operator defined on some neighborhood V of $\{0\} \times \Sigma$ in $\mathbb{R} \times \Sigma$. To define a proper *inverse* K^{-1} , we need some realization of K as an unbounded operator. As turns out, the natural way is to realize K by imposing *Dirichlet boundary conditions* on a sufficiently small neighborhood Ω of $\{0\} \times \Sigma$ in $\mathbb{R} \times \Sigma$.

3.1. Gaussian normal coordinates. Let us consider a globally hyperbolic analytic spacetime (M, g) with an analytic spacelike Cauchy hypersurface Σ .

Using Gaussian normal coordinates to Σ , we obtain neighborhoods U of $\{0\} \times \Sigma$ in $\mathbb{R} \times \Sigma$ and U' of Σ in M and an isometric diffeomorphism

$$(3.1) \quad \chi : (U, -dt^2 + h_t(y)dy^2) \rightarrow (U', g),$$

where if $K \subseteq \Sigma$ and $\epsilon > 0$ is such that $] - \epsilon, \epsilon[\times K \subset U$, then $] - \epsilon, \epsilon[\ni t \mapsto h_t(y)dy^2$ is a t -dependent Riemannian metric on K . In particular $h_0(y)dy^2$ is the Riemannian metric induced by g on Σ .

By the Cauchy-Kowalevski theorem, it follows from the fact that (M, g) and Σ are analytic, that $\chi : U \rightarrow U'$ is analytic, and that $U \ni (t, y) \mapsto h_t(y)dy^2$ is an analytic $(2, 0)$ tensor.

It will turn out convenient later on to assume that

$$(3.2) \quad \text{the Riemannian manifold } (\Sigma, h_0) \text{ is complete.}$$

Let us explain how to reduce ourselves to this situation.

It is known, see e.g. [Kn], that there exists a real analytic function $c : \Sigma \rightarrow]0, +\infty[$ such that $c^2 h_0$ is complete on Σ .

We extend c to $U \subset \mathbb{R} \times \Sigma$ by $c(t, y) = c(y)$, push it to U' by χ and consider the Lorentzian metric $\tilde{g} = c^2 g$. Clearly $(U', \tilde{g})$ is globally hyperbolic with Σ as a spacelike Cauchy hypersurface.

By Prop. 2.12, to construct analytic Hadamard states for some analytic Klein-Gordon operator P on (M, g) , it suffices to perform the construction on $(U, \tilde{g})$, for some conformally rescaled analytic Klein-Gordon operator $\tilde{P}$. Denoting U by M and $\tilde{g}$ again by g , we can hence assume without loss of generality that (3.2) holds.

3.2. Klein-Gordon operator in Gaussian normal coordinates. Denoting the operator $\chi^* P$ by P again, we obtain that

$$(3.3) \quad P = \partial_t^2 + r(t, y)\partial_t + a(t, y, \partial_y),$$

where

$$r(t, y) = |h_t(y)|^{-\frac{1}{2}} \partial_t |h_t(y)|^{\frac{1}{2}},$$

and

$$a(t, y, \partial_y) = |h_t(y)|^{-\frac{1}{2}} \partial_j |h_t(y)|^{\frac{1}{2}} h_t^{jk}(y) \partial_k + V(t, y).$$

The operator $a(t, y, \partial_y)$ is selfadjoint for the scalar product

$$(u|v) = \int_U \bar{u}v |h_t|^{\frac{1}{2}} dy dt.$$

3.2.1. *Reduction of P .* It is possible to reduce oneself to the case where $r(t, y) \equiv 0$. In fact if

$$(3.4) \quad d(t, y) = |h_t(y)|^{1/4} |h_0(y)|^{-1/4},$$

we see that

$$d : L^2(U, |h_t|^{1/2} dt dy) \ni u \mapsto du \in L^2(U, |h_0|^{1/2} dt dy)$$

is unitary and

$$(3.5) \quad P_0 := d P d^{-1} = \partial_t^2 + a_0(t, y, \partial_y),$$

for

$$(3.6) \quad a_0(t, y, \partial_y) = d(t, y) a(t, y, \partial_y) d^{-1}(t, y) - \frac{r^2(t, y)}{4} - \frac{1}{2} \partial_t r(t, y),$$

which is selfadjoint for the scalar product

$$(3.7) \quad (u|v)_0 = \int_U \bar{u} v |h_0|^{1/2} dy dt.$$

3.3. Wick rotated operator. The function $t \mapsto r(t, \cdot)$ and the differential operator $t \mapsto a(t, y, \partial_y)$ extend holomorphically in t in a neighborhood W of $\{0\} \times \Sigma$ in $\mathbb{C} \times \Sigma$. We can moreover assume that W is small enough such that for each $\alpha \in \mathbb{R}$ the functions $U \ni (t, y) \mapsto |h_t(y)|^\alpha$ extend holomorphically in t to W . In particular $d(t, y)$ defined in (3.4) extends holomorphically in t to W .

We define the *Wick rotated operator*:

$$(3.8) \quad K = -\partial_s^2 - i r(is, y) \partial_s + a(is, y, \partial_y), \quad (s, y) \in V,$$

where V is a neighborhood of $\{0\} \times \Sigma$ in $\mathbb{R} \times \Sigma$. By possibly replacing it by a smaller neighborhood, we can assume that V is invariant under the reflection $(s, y) \mapsto (-s, y)$.

The operator K is obtained from P by the substitution $t \rightarrow is$. It has analytic coefficients in (s, y) on V .

3.3.1. *Reduction of K .* The reduction of P in 3.2.1 can be similarly carried out for K . In fact let us set:

$$(3.9) \quad \hat{h}_s(y) = (h_{is}^* h_{is})^{1/2}(y), \quad (s, y) \in U.$$

which is positive definite. Note that from $h_t(y) = h_t(y)^*$, we obtain $h_{is}(y)^* = h_{-is}(y)$ hence:

$$(3.10) \quad |\hat{h}_s(y)| = |\hat{h}_{-s}(y)|, \quad (s, y) \in U.$$

We also set:

$$(3.11) \quad \hat{d}(s, y) = |h_{is}(y)|^{1/4} |h_0(y)|^{-1/4} = d(is, y)$$

for d defined in (3.4). We see that

$$(3.12) \quad \hat{d} : L^2(U, |\hat{h}_s|^{1/2} dy ds) \ni u \mapsto du \in L^2(U, |h_0|^{1/2} dy ds)$$

is unitary and from (3.5) we obtain that:

$$(3.13) \quad \hat{d} K \hat{d}^{-1} =: K_0 = -\partial_s^2 + a_0(is, y, \partial_y).$$

From the selfadjointness of $a_0(t, y, \partial_y)$ we obtain that

$$a_0(is, y, \partial_y)^* = a_0(-is, y, \partial_y)$$

on $L^2(U, |h_0|^{\frac{1}{2}} dy ds)$.

3.4. Some preparations. The operators K or K_0 are elliptic differential operators, but have for the moment no realizations as unbounded operators with some concrete domain. We will fix such a realization by introducing *Dirichlet boundary conditions* on the boundary of some open set $\Omega \subset V$. In this subsection we collect some properties obtained from a convenient choice of Ω .

Lemma 3.1. *Let $\Sigma = \bigcup_{i \in \mathbb{N}} U_i$ be a covering of Σ with $U_i \Subset \Sigma$. Then there exist T_i , $i \in \mathbb{N}$ such that for all $(s, y) \in]-T_i, T_i[\times U_i$ and all $v, v_1, v_2 \in \mathcal{C}T_y \Sigma$ one has:*

$$\begin{aligned}
 (3.14) \quad & i) \quad \frac{1}{2} \bar{v} \cdot h_0(y) v \leq \bar{v} \cdot \operatorname{Re} h_{is}(y) v \leq \frac{3}{2} \bar{v} \cdot h_0(y) v, \\
 & ii) \quad |\bar{v} \cdot \operatorname{Im} h_{is}(y) v| \leq \frac{1}{2} \bar{v} \cdot h_0(y) v, \\
 & iii) \quad |\bar{v}_1 \cdot h_{is}(y) v_2| \leq 2(\bar{v}_1 \cdot h_0(y) v_1)^{\frac{1}{2}} (\bar{v}_2 \cdot h_0(y) v_2)^{\frac{1}{2}} \\
 & iv) \quad \frac{1}{2} \leq |\hat{d}(s, y)| \leq 1, \\
 & v) \quad \nabla \hat{d}(s, y) \cdot h_0(y) \nabla \hat{d}(s, y) \leq 1.
 \end{aligned}$$

Proof. *i) and ii) are obvious and imply iii). iv) and v) follow from $\hat{d}(0, y) \equiv 1$. $\square$*

Let $\Omega \subset U$ be an open neighborhood of $\{0\} \times \Sigma$ with a smooth boundary. For $s \in \mathbb{R}$ we denote by $H_c^s(\Omega)$, $H_{\text{loc}}^s(\Omega)$ the compactly supported and local Sobolev spaces of order s . We denote by $H_0^1(\Omega)$ the closure of $C_c^\infty(\Omega)$ for the norm

$$\|u\|_{H^1(\Omega)}^2 = \int_{\Omega} (|\partial_s u|^2 + \partial_j \bar{u} h_0^{jk} \partial_k u + |u|^2) |h_0|^{\frac{1}{2}} dy ds.$$

Note that if $(U_i, T_i)_{i \in \mathbb{N}}$ are as in Lemma 3.1 and $\Omega \subset \bigcup_{i \in \mathbb{N}}]-T_i, T_i[\times U_i$, it follows from Lemma 3.1 iv) and v) that

$$(3.15) \quad \hat{d} : H_0^1(\Omega) \xrightarrow{\sim} H_0^1(\Omega).$$

In Prop. 3.2 below the space $L^2(\Omega, |\hat{h}_s(y)|^{\frac{1}{2}} ds dy)$ is denoted by $L^2(\Omega)$.

If A is a closed operator, its resolvent set is denoted by $\operatorname{rs}(A)$.

Proposition 3.2. *Let Q_Ω be the sesquilinear form:*

$$Q_\Omega(v, u) = (v | K u)_{L^2(\Omega)}, \quad \operatorname{Dom} Q_\Omega = C_c^\infty(\Omega).$$

Then there exists an Ω as above such that:

- (1) Ω is invariant under $i : (s, y) \mapsto (-s, y)$;
- (2) Q_Ω and Q_Ω^* are closeable on $L^2(\Omega)$;
- (3) their closures $\overline{Q_\Omega}$, $\overline{Q_\Omega^*}$ are sectorial, with domain $H_0^1(\Omega)$;
- (4) the closed operators K_Ω , K_Ω^* associated to $\overline{Q_\Omega}$, $\overline{Q_\Omega^*}$ satisfy $0 \in \operatorname{rs}(K_\Omega)$, $0 \in \operatorname{rs}(K_\Omega^*)$;
- (5) K_Ω^* is the adjoint of K_Ω .

Proof. Let us denote $L^2(V, |h_0|^{\frac{1}{2}}(y) ds dy)$ by $L_0^2(V)$ and similarly $L^2(\Sigma, |h_0|^{\frac{1}{2}} dy)$ by $L_0^2(\Sigma)$. We first consider the sesquilinear form

$$Q_0(v, u) = (\partial_s v | \partial_s u)_{L_0^2(V)} + (v | a_0(is)u)_{L_0^2(V)}, \quad \operatorname{Dom} Q_0 = C_c^\infty(\Omega).$$

Let $\Sigma = \bigcup_{i \in \mathbb{N}} U_i$ a covering of Σ and $1 = \sum_{i \in \mathbb{N}} \chi_i^2(y)$, $\chi_i \in C_c^\infty(U_i)$ a subordinate partition of unity on Σ . Let us set

$$b(s) = \operatorname{Re} a_0(is), \quad c(s) = \operatorname{Im} a_0(is), \quad k_0 = -\Delta_{h_0} + 1,$$

where the real and imaginary parts are computed w.r.t. the scalar product in $L_0^2(\Sigma)$. We have

$$\begin{aligned} (3.16) \quad b(s) &= \sum_{i \in \mathbb{N}} \chi_i b(s) \chi_i + m(s), \quad m(s) = \frac{1}{2} \sum_i [\chi_i, [\chi_i, b(s)]], \\ c(s) &= \sum_{i \in \mathbb{N}} \chi_i c(s) \chi_i + n(s), \quad n(s) = \frac{1}{2} \sum_i [\chi_i, [\chi_i, c(s)]], \\ k_0 &= \sum_{i \in \mathbb{N}} \chi_i k_0 \chi_i + m_0, \quad m_0 = \frac{1}{2} \sum_i [\chi_i, [\chi_i, k_0]]. \end{aligned}$$

Moreover, $b(s)$ is a second order elliptic operator, formally selfadjoint on $L_0^2(\Sigma)$, with principal symbol $\eta \cdot \operatorname{Re} h_{is}^{-1}(y) \eta$. By Lemma 3.1 *i)* and *ii)* there exist $c_i, T_i > 0$ such that:

$$\begin{aligned} (3.17) \quad \frac{1}{2} \chi_i k_0 \chi_i - \chi_i c_i \chi_i &\leq \chi_i b(s) \chi_i \leq \frac{3}{2} \chi_i k_0 \chi_i + \chi_i c_i \chi_i, \\ -\frac{1}{2} \chi_i k_0 \chi_i - \chi_i c_i \chi_i &\leq \chi_i c(s) \chi_i \leq \frac{1}{2} \chi_i k_0 \chi_i + \chi_i c_i \chi_i \end{aligned}$$

on $L_0^2(\Sigma)$ for $|s| \leq T_i$. Since $m(s), n(s), m_0$ are multiplication operators on Σ , there exist constants c'_i such that

$$\chi_i(|m|(s) + |n|(s) + |m_0|) \chi_i \leq c'_i \chi_i^2, \quad \text{on } L_0^2(\Sigma), \quad \text{for } |s| \leq T'_i.$$

It follows that

$$(3.18) \quad |m| + |n| + |m_0| \leq \sum_{i \in \mathbb{N}} c'_i \chi_i^2,$$

on $L_0^2(\bigcup_{i \in \mathbb{N}} U_i \times] - S_i, S_i[)$, if $0 < S_i < T'_i$. By (3.16), (3.17), (3.18) we obtain:

$$\begin{aligned} (3.19) \quad \frac{1}{2} k_0 - \sum_i (c_i + \frac{1}{2} c'_i) \chi_i^2 &\leq b \leq \frac{3}{2} k_0 + \sum_i (c_i + \frac{3}{2} c'_i) \chi_i^2, \\ -\frac{1}{2} k_0 - \sum_i (c_i + \frac{1}{2} c'_i) \chi_i^2 &\leq c \leq \frac{1}{2} k_0 + \sum_i (c_i + c'_i) \chi_i^2, \end{aligned}$$

on $L_0^2(\bigcup_{i \in \mathbb{N}} U_i \times] - S_i, S_i[)$, if $0 < S_i < \min(T_i, T'_i)$.

By the Poincaré inequality we can find $T''_i > 0$ such that

$$(3.20) \quad (\partial_s u | \partial_s u)_{L_0^2(V)} \geq (2c_i + 2c'_i + 1)(u | u)_{L_0^2(V)}, \quad u \in C_c^\infty(] - T''_i, T''_i[\times \Sigma).$$

Let now $S_i = \min(T_i, T'_i, T''_i)$ and $\Omega \subset \bigcup_{i \in \mathbb{N}}] - S_i, S_i[\times U_i$ an open neighborhood of $\{0\} \times \Sigma$ with a smooth boundary and $i(\Omega) = \Omega$. We have by (3.20):

$$\begin{aligned} (3.21) \quad (\partial_s u | \partial_s u)_{L_0^2(V)} &= \sum_{i \in \mathbb{N}} (\partial_s \chi_i u | \partial_s \chi_i u)_{L_0^2(V)} \\ &\geq (2c_i + 2c'_i + 1)(u | \chi_i^2 u)_{L_0^2(V)}, \quad u \in C_c^\infty(\Omega), \end{aligned}$$

since $\operatorname{supp} u \subset \Omega$ implies $\operatorname{supp} \chi_i u \subset] - T''_i, T''_i[\times \Sigma$. Let us denote by Q_{ref} the hermitian form

$$Q_{\text{ref}}(v, u) = (\partial_s v | \partial_s u)_{L^2(V)} + (v | k_0 u)_{L^2(V)}, \quad \operatorname{Dom} Q_{\text{ref}} = C_c^\infty(\Omega).$$

we obtain from (3.19), (3.21):

$$\begin{aligned} (3.22) \quad \frac{1}{2} Q_{\text{ref}}(u, u) &\leq \operatorname{Re} Q_0(u, u) \leq \frac{3}{2} Q_{\text{ref}}(u, u), \\ |\operatorname{Im} Q_0(u, u)| &\leq \frac{1}{2} \operatorname{Re} Q_{\text{ref}}(u, u), \quad u \in C_c^\infty(\Omega). \end{aligned}$$

The form Q_{ref} is closeable, strictly positive and its closure $\overline{Q}_{\text{ref}}$ has domain $H_0^1(\Omega)$. From (3.22) we obtain that Q_0 is closeable on $C_c^\infty(\Omega)$, and its closure $\overline{Q}_0$ has domain $H_0^1(\Omega)$ and is sectorial. By [K, VI.2.1] the associated operator $K_{\Omega,0}$ is closed, sectorial with $0 \in \text{rs}(K_{\Omega,0})$.

The same is true of the form Q_0^* and if $K_{\Omega,0}^*$ is the operator associated to its closure, we have $K_{\Omega,0}^* = (K_\Omega)^*$ by [K, Thm. VI.2.5].

Next, we set $K_\Omega := \hat{d}^{-1} K_{\Omega,0} \hat{d}$ with domain $\hat{d}^{-1} \text{Dom } K_{\Omega,0}$. Using (3.12) and (3.13) we see that Q_Ω, Q_Ω^* are closeable, with associated operators K_Ω, K_Ω^* and $K_\Omega^* = \hat{d}^{-1} K_{\Omega,0}^* \hat{d} = (K_\Omega)^*$. $\square$

We end this section with a lemma which states that away from $\partial\Omega$, K_Ω^{-1} is given by a pseudodifferential operator on Ω of order -2 .

We denote by $\Psi_c^m(\Omega)$ the space of classical, properly supported pseudodifferential operators of order $m \in \mathbb{R}$, see e.g. [Sh], and by $\mathcal{W}^{-\infty}(\Omega)$ the space of *smoothing operators*, i.e. linear operators on Ω with smooth distributional kernels. We set $\Psi^m(\Omega) = \Psi_c^m(\Omega) + \mathcal{W}^{-\infty}(\Omega)$ and

$$(3.23) \quad \Psi_{(c)}^\infty(\Omega) = \bigcup_{m \in \mathbb{R}} \Psi_{(c)}^m(\Omega).$$

Lemma 3.3. *Let $\varphi_1, \varphi_2 \in C_c^\infty(\Omega)$ with $\varphi_1 = 1$ near $\text{supp } \varphi_2$. Then there exist $Q \in \Psi_c^{-2}(\Omega)$ such that*

$$\varphi_1 K_\Omega^{-1} \varphi_2 = \varphi_1 Q \varphi_2 + R_{-\infty}, \quad R_{-\infty} \in \mathcal{W}^{-\infty}(\Omega).$$

Proof. From Lemma 3.1 we obtain that $|\eta \cdot h_{\text{is}}^{-1}(y) \eta| \geq c_0 \eta \cdot h_0^{-1}(y) \eta$ for $(s, y) \in \Omega$, $\eta \in T_y^* \Sigma$, hence K is elliptic on Ω . It is well known that K admits a properly supported *parametrix*, i.e. some $Q \in \Psi_c^{-2}(\Omega)$ such that:

$$KQ - \mathbb{1}, QK - \mathbb{1} \in \mathcal{W}^{-\infty}(\Omega).$$

We can moreover assume that $(1 - \varphi_1)Q\varphi_2 = 0$ hence:

$$KQ\varphi_2 = \varphi_2 + \varphi_1 R_{-\infty} \varphi_2, \quad R_{-\infty} \in \mathcal{W}^{-\infty}(\Omega).$$

Since $\varphi_1 = 0$ near $\partial\Omega$, this implies that

$$\varphi_1 Q \varphi_2 = Q \varphi_2 = K_\Omega^{-1}(\varphi_2 + \varphi_1 R_{-\infty} \varphi_2) = \varphi_1 K_\Omega^{-1} \varphi_2 + \varphi_1 K_\Omega^{-1} \varphi_1 R_{-\infty} \varphi_2.$$

By elliptic regularity $K_\Omega^{-1} : H_c^s(\Omega) \rightarrow H_{\text{loc}}^{s+2}(\Omega)$, hence $\varphi_1 K_\Omega^{-1} \varphi_1 R_{-\infty} \varphi_2 \in \mathcal{W}^{-\infty}(\Omega)$. This completes the proof. $\square$

4. CALDERÓN PROJECTORS AND HADAMARD STATES

In this section we construct the *Calderón projectors* $C_\Omega^\pm$ associated to K_Ω . We show that they define a pure quasi-free state for the analytic Klein-Gordon operator P .

4.1. Notation. Let us fix an open set $\Omega \subset V$ such that Lemma 3.1 and Prop. 3.2 hold. If $\Omega_1 \subset \Omega$ is open and $F(\Omega) \subset \mathcal{D}'(\Omega)$ is a space of distributions, we denote by $\overline{F}(\Omega_1) \subset \mathcal{D}'(\Omega_1)$ the space of *restrictions* of elements of $F(\Omega)$ to Ω_1 .

It is well known that any $u \in \overline{\mathcal{D}'}(\Omega_1)$ has a unique extension $eu \in \mathcal{D}'(\Omega)$ with $eu = 0$ on $\Omega \setminus \Omega_1^{\text{cl}}$. We will apply this to the open sets:

$$\Omega^\pm := \Omega \cap \{\pm s > 0\}.$$

For example elements of $\overline{C^\infty}(\Omega^\pm)$ are functions in $C^\infty(\Omega^\pm)$ which extend smoothly across $s = 0$, while elements of $\overline{C_c^\infty}(\Omega^\pm)$ have additionally a compact support in $\overline{\Omega^+}$ and vanish near $\partial\Omega^\pm \cap \{\pm s > 0\}$ (but not necessarily near $\Sigma = \partial\Omega^\pm \cap \{s = 0\}$). Similarly elements of $\overline{H_0^1}(\Omega^\pm)$ are functions in $H^1(\Omega^\pm)$ which vanish on $\partial\Omega^\pm \cap \{\pm s > 0\}$, but not necessarily on Σ .

We denote by $r^\pm : \mathcal{D}'(\Omega) \rightarrow \overline{\mathcal{D}'}(\Omega^\pm)$, resp. $e^\pm : \overline{\mathcal{D}'}(\Omega^\pm) \rightarrow \mathcal{D}'(\Omega)$ the operators of restriction, resp. extension by 0.

We define the trace operator by

$$\gamma u = \begin{pmatrix} u|_\Sigma \\ -\partial_s u|_\Sigma \end{pmatrix}, \quad u \in C^\infty(\Omega).$$

We denote by $\gamma^\pm$ the analogous trace operators defined on $\overline{C^\infty}(\Omega^\pm)$.

We set

$$\mathcal{H}^{(\pm)} = L^2(\Omega^{(\pm)}, |\hat{h}_s|^{\frac{1}{2}} ds dy), \quad \mathcal{H}_0^{(\pm)} = L^2(\Omega^{(\pm)}, |h_0|^{\frac{1}{2}} ds dy),$$

and

$$\mathcal{S} = L^2(\Sigma, |h_0|^{\frac{1}{2}} dy) \otimes \mathbb{C}^2.$$

We denote by $\gamma^* : \mathcal{E}'(\Sigma)^2 \rightarrow \mathcal{D}'(\Omega)$ the formal adjoint of $\gamma : C_c^\infty(\Omega) \rightarrow C_c^\infty(\Sigma)^2$ when $C_c^\infty(\Omega)$, resp. $C_c^\infty(\Sigma)^2$ is equipped with the scalar products of $\mathcal{H}$, resp. $\mathcal{S}$. We have:

$$(4.1) \quad \gamma^* f = \delta(s) \otimes f_0 + \delta'(s) \otimes f_1, \quad f = \begin{pmatrix} f_0 \\ f_1 \end{pmatrix} \in C_c^\infty(\Sigma)^2.$$

This follows from the fact that $\partial_s |\hat{h}_s(y)|^{\frac{1}{2}}$ vanishes at $s = 0$, because of (3.10).

4.2. Some identities. Let us set:

$$(4.2) \quad \begin{aligned} R &= \begin{pmatrix} \mathbb{1} & 0 \\ \partial_s \hat{d}(0, y) & \mathbb{1} \end{pmatrix}, \quad q = \begin{pmatrix} 0 & \mathbb{1} \\ \mathbb{1} & 0 \end{pmatrix}, \\ S &= \begin{pmatrix} 2i\partial_t d(0, y) & -\mathbb{1} \\ \mathbb{1} & 0 \end{pmatrix}, \quad S_0 = \begin{pmatrix} 0 & -\mathbb{1} \\ \mathbb{1} & 0 \end{pmatrix}. \end{aligned}$$

The following identities are straightforward to check:

$$(4.3) \quad \gamma^{(\pm)} \circ \hat{d} = R \circ \gamma^{(\pm)}, \quad R^* q R = q, \quad R^* S_0 R = S.$$

The lemma below is proved by direct computations, using the form of K_0 in (3.13) and integration by parts.

Lemma 4.1. *Let $u \in \overline{C^\infty}(\Omega^\pm)$, $v \in \overline{C_c^\infty}(\Omega^\pm)$. Then:*

$$(4.4) \quad (v|K_0 u)_{\mathcal{H}_0^\pm} - (K_0^* v|u)_{\mathcal{H}_0^\pm} = \pm (\gamma^\pm v|S_0 \gamma^\pm u)_{\mathcal{S}}.$$

$$(4.5) \quad \begin{aligned} & (v|K_0 u)_{\mathcal{H}_0^\pm} + (K_0 v|u)_{\mathcal{H}_0^\pm} \\ &= 2(\partial_s v|\partial_s u)_{\mathcal{H}_0^\pm} + (v|(a_0(is) + a_0(is)^*)u)_{\mathcal{H}_0^\pm} \mp (\gamma^\pm v|q\gamma^\pm u)_{\mathcal{S}}. \end{aligned}$$

The following proposition will be needed in the proof of Thm. 4.5 below. It is superfluous if the Cauchy hypersurface Σ is compact.

For $\chi \in C_c^\infty(\Sigma)$ we set $\|\nabla \chi\|_\infty = \sup_{y \in \Sigma} |\partial_j \chi(y) h_0^{jk}(y) \partial_k \chi(y)|^{\frac{1}{2}}$.

Proposition 4.2. *Let χ be a compactly supported Lipschitz function on (Σ, h_0) . There exists $c_0 > 0$ such that for all $u, v \in \overline{H_0^1}(\Omega^\pm)$:*

$$\begin{aligned} |(\chi v|[a_0(is), \chi]u)_{\mathcal{H}_0^\pm}| &\leq c_0(\|\chi\|_\infty \|\nabla \chi\|_\infty + \|\nabla \chi\|_\infty^2) \|v\|_{H^1(\Omega^\pm)} \|u\|_{H^1(\Omega^\pm)}, \\ |(\chi v|[a_0(is)^*, \chi]u)_{\mathcal{H}_0^\pm}| &\leq c_0(\|\chi\|_\infty \|\nabla \chi\|_\infty + \|\nabla \chi\|_\infty^2) \|v\|_{H^1(\Omega^\pm)} \|u\|_{H^1(\Omega^\pm)}. \end{aligned}$$

Proof. Let us set $\hat{d}_s(y) = \hat{d}(s, y)$. It suffices to prove the result for $a_0(is)$, using that $a_0(is)^* = a_0(-is)$. Moreover by density we can assume that $u, v \in \overline{C_c^\infty}(\Omega^\pm)$. From (3.13) we obtain that $[a_0(is), \chi] = \hat{d}_s[a(is), \chi]\hat{d}_s^{-1}$ and

$$[a(is), \chi]u = -\partial_j \chi h_{is}^{jk} \partial_k u - |h_{is}|^{-\frac{1}{2}} \partial_j (h_{is}^{jk} |h_{is}|^{\frac{1}{2}} \partial_k \chi u).$$

It follows that

$$\begin{aligned} (\chi v|[a_0(is), \chi]u)_{\mathcal{H}_0^\pm} &= (\chi v|\hat{d}_s[a(is), \chi]\hat{d}_s^{-1}u)_{\mathcal{H}_0^\pm} \\ &= - \int_{\Omega^\pm} \chi \bar{v} \partial_j \chi h_{is}^{jk} \hat{d}_s \partial_k (\hat{d}_s^{-1}u) |h_0|^{\frac{1}{2}} ds dy \\ &\quad - \int_{\Omega^\pm} \hat{d}_s |h_0|^{\frac{1}{2}} |h_{is}|^{-\frac{1}{2}} \chi \bar{v} \partial_j (h_{is}^{jk} |h_{is}|^{\frac{1}{2}} \partial_k \chi \hat{d}_s^{-1}u) ds dy \\ &= - \int_{\Omega^\pm} \chi \bar{v} \partial_j \chi h_{is}^{jk} \hat{d}_s \partial_k (\hat{d}_s^{-1}u) |h_0|^{\frac{1}{2}} ds dy \\ &\quad + \int_{\Omega^\pm} \hat{d}_s \partial_j (\hat{d}_s^{-1} \chi \bar{v}) h_{is}^{jk} \partial_k \chi u |h_0|^{\frac{1}{2}} ds dy, \end{aligned}$$

where we integrate by parts the second term and use that $\hat{d}_s = |h_0|^{-1/4} |h_{is}|^{1/4}$. Expanding the derivatives, we obtain:

$$\begin{aligned} &(\chi v|[a_0(is), \chi]u)_{\mathcal{H}_0^\pm} \\ &= - \int_{\Omega^\pm} \chi \bar{v} \partial_j \chi h_{is}^{jk} \hat{d}_s \partial_k u |h_0|^{\frac{1}{2}} ds dy + \int_{\Omega^\pm} \chi \bar{v} \partial_j \chi h_{is}^{jk} \partial_k (\ln \hat{d}_s) u |h_0|^{\frac{1}{2}} ds dy \\ &\quad + \int_{\Omega^\pm} \chi \partial_j \bar{v} h_{is}^{jk} \partial_k \chi u |h_0|^{\frac{1}{2}} ds dy + \int_{\Omega^\pm} \bar{v} \partial_j \chi h_{is}^{jk} \partial_k \chi u |h_0|^{\frac{1}{2}} ds dy \\ &\quad - \int_{\Omega^\pm} \chi \bar{v} \partial_j (\ln(\hat{d}_s)) h_{is}^{jk} \partial_k \chi u |h_0|^{\frac{1}{2}} ds dy. \end{aligned}$$

We can use Lemma 3.1 *iii)* to bound scalar products involving $h_{is}(y)$ by scalar products involving $h_0(y)$. We also know from Lemma 3.1 *iv), v)* that:

$$|\partial_j (\ln \hat{d}_s(y)) h_{is}^{jk}(y) \partial_k \chi(y)| \leq c_0 |\partial_j \chi(y) h_0^{jk}(y) \partial_k \chi(y)|, \quad \forall (s, y) \in \Omega.$$

Using the Cauchy-Schwarz inequality we obtain that

$$|(\chi v|[a_0(is), \chi]u)_{\mathcal{H}_0^\pm}| \leq c_0(\|\chi\|_\infty \|\nabla \chi\|_\infty + \|\nabla \chi\|_\infty^2) \|v\|_{H^1(\Omega^\pm)} \|u\|_{H^1(\Omega^\pm)}.$$

This completes the proof. $\square$

4.3. The Calderón projectors.

Definition 4.3. *Let $\Omega \Subset V$ be as in Prop. 3.2. The Calderón projectors for K_Ω are the operators*

$$C_\Omega^\pm := \mp \gamma^\pm K_\Omega^{-1} \gamma^* S.$$

Note that it is not a priori clear that $C_\Omega^\pm$ are well defined, even as maps from $C_c^\infty(\Sigma)^2$ to $\mathcal{D}'(\Sigma)^2$. Despite their name, it is even less clear whether $C_\Omega^\pm$ are projectors on suitable spaces. Let us start by reviewing basic properties of $C_\Omega^\pm$, which are well known if Σ is compact. We refer the reader to the book [Gr, Chap. 11] for details on the compact case.

We recall that the pseudodifferential operator classes $\Psi^\infty(\Sigma)$ were introduced in (3.23).

Proposition 4.4. (1) $C_\Omega^\pm$ map $C_c^\infty(\Sigma)^2$ continuously into $C^\infty(\Sigma)^2$;
 (2) $C_\Omega^\pm$ are given by 2×2 matrices with entries in $\Psi^\infty(\Sigma)$.

Proof. To prove (1) we can replace K_Ω^{-1} by $\varphi_1 K_\Omega^{-1} \varphi_2$ for $\varphi_i \in C_c^\infty(\Omega)$ equal to 1 on some neighborhood of $U_i \subseteq \Sigma$. By Lemma 3.3 we can then replace $\varphi_1 K_\Omega^{-1} \varphi_2$ by $\varphi_1 Q \varphi_2$ where $Q \in \Psi_c^{-2}(\Omega)$ is a properly supported pseudodifferential operator. The proofs in [Gr, Chap. 11] can be then applied directly to get (1).

It also follows from [Gr, Chap. 11] that if $\psi \in C_c^\infty(\Sigma)$, then $\psi C_\Omega^\pm \psi$ is given by a 2×2 matrix with entries in $\Psi_c^\infty(\Sigma)$. To prove (2) it hence remains to show that if $\psi_1, \psi_2 \in C_c^\infty(\Sigma)$ have disjoint supports, then $\psi_1 C_\Omega^\pm \psi_2$ is a smoothing operator on Σ . Clearly we can find $\varphi_i \in C_c^\infty(\Omega)$ with disjoint supports such that $\varphi_i = 1$ near $\{0\} \times \text{supp } \psi_i$. Then in the formula defining $\psi_1 C_\Omega^\pm \psi_2$ we can replace K_Ω^{-1} by $\varphi_1 K_\Omega^{-1} \varphi_2$, which is smoothing by Lemma 3.3. Therefore $\psi_1 C_\Omega^\pm \psi_2$ is smoothing, which completes the proof of (2). $\square$

Theorem 4.5. Let $\Omega \subseteq V$ be as in Prop. 3.2. The following properties hold true:

(1) one has

$$C_\Omega^+ + C_\Omega^- = \mathbb{1} \text{ on } C_c^\infty(\Sigma)^2;$$

(2) setting $\lambda^\pm := \pm q \circ C_\Omega^\pm$ one has

$$(f|\lambda^\pm f)_S \geq 0, \quad \forall f \in C_c^\infty(\Sigma)^2.$$

It follows from the general arguments recalled in 2.1.4 that $\lambda^\pm$ are a pair of Cauchy surface two-point functions for the analytic Klein-Gordon operator P .

Definition 4.6. We denote by ω_Ω the quasi-free state with Cauchy surface covariances given by the sesquilinear forms $(\cdot|\lambda^\pm \cdot)_S$.

Before starting the proof of Thm. 4.5 we state a result about smooth approximations of the distance function on (Σ, h) , which follows from [AFLR, Thm. 1].

Proposition 4.7. Suppose that Σ is not compact and let $d(y, y')$ be the geodesic distance for h_0 . Then for any fixed $y^0 \in \Sigma$, there exists $r \in C^\infty(\Sigma)$ such that:

- i) $\frac{1}{2}d(y^0, y) \leq r(y) \leq 2d(y^0, y),$
- ii) $\|\nabla r\|_\infty \leq 2.$

Proof of Thm. 4.5. For ease of notation we will drop the Ω subscripts in the sequel. The proof consists of several steps.

Step 1. We first claim that it suffices to prove the theorem for K_0 instead of K . In fact let $C_0^\pm = \mp \gamma^\pm K_0^{-1} \gamma_0^* S_0$ be the analogue of $C_\Omega^\pm$, defined using K_0 , where γ_0^* is defined as the formal adjoint of $\gamma : \mathcal{H}_0 \rightarrow \mathcal{S}$. Note that $\gamma_0^* = \gamma^*$.

We recall that:

$$\begin{aligned} K_\Omega^{-1} &= \hat{d}^{-1} K_0^{-1} \hat{d}, \quad \gamma^{(\pm)} = R^{-1} \gamma_0^{(\pm)} \hat{d}, \\ \gamma^* &= \hat{d}^{-1} \gamma_0^* (R^{-1})^*, \quad S = R^* S_0 R, \end{aligned}$$

which implies that

$$C_\Omega^\pm = R^{-1} C_0^\pm R.$$

Since $q = R^* q R$ it suffices to prove the theorem for $C_0^\pm$.

Step 2. In Step 2 we prove (1).

Let us consider

$$u^\pm = r^\pm K_0^{-1} \gamma_0^* S_0 f, \text{ for } f \in C_c^\infty(\Sigma)^2.$$

Using the ellipticity of K_0 and the fact that K_0^{-1} is a pseudodifferential operator away from $\partial\Omega$, one can prove that $u^\pm \in \overline{H_0^1}(\Omega^\pm) \cap \overline{C^\infty}(\Omega^\pm)$, see Lemma A.1 in the appendix.

Let $f, g \in C_c^\infty(\Sigma)^2$. We fix $v \in C_c^\infty(\Omega)$ such that $\gamma v = g$ and set $u^\pm = \mp r^\pm K_0^{-1} \gamma^* S_0 f$ so that $\gamma^\pm u^\pm = C_0^\pm f$. We have:

$$\begin{aligned} (g|S_0(C^+ + C^-)f)_\mathcal{S} &= (\gamma^+ r^+ v|S_0 \gamma^+ u^+)_\mathcal{S} + (\gamma^- r^- v|S_0 \gamma^- u^-)_\mathcal{S} \\ &= (r^+ v|K_0 u^+)_{\mathcal{H}_0^+} - (r^+ K_0^* v|u^+)_{\mathcal{H}_0^+} \\ &\quad - (r^- v|K_0 u^-)_{\mathcal{H}_0^-} + (r^- K_0^* v|u^-)_{\mathcal{H}_0^-} \\ (4.6) \quad &= -(r^+ K_0^* v|u^+)_{\mathcal{H}_0^+} + (r^- K_0^* v|u^-)_{\mathcal{H}_0^-} \\ &= (K_0^* v|K_0^{-1} \gamma^* S_0 f)_{\mathcal{H}_0} = (v|\gamma^* S_0 f)_{\mathcal{H}_0} \\ &= (\gamma v|S_0 f)_\mathcal{S} = (g|S_0 f)_\mathcal{S}. \end{aligned}$$

In the second line we used (4.4), and then we used that $K_0 u^\pm = 0$ in $\Omega^\pm$. Next, in the next lines we used that $v \in C_c^\infty(\Omega)$ and hence $K_0^* v = (K_0)^* v$. Since g is arbitrary and S_0 is injective, (4.6) implies that $C_0^+ f + C_0^- f = f$, which completes the proof of (1).

Step 3. In Step 3 we prove (2). For simplicity we consider only the case of C_0^+ , the case of C_0^- being similar. Let $f \in C_c^\infty(\Sigma)^2$ and $u^+ = r^+ K_0^{-1} \gamma_0^* S_0 f$. The idea is to apply the identities (4.4), (4.5) to $v = u = u^+$. However since we do not know if $\gamma^+ u \in L^2(\Sigma)^2$, the boundary terms in these identities may be ill defined. Therefore we need some extra approximation argument. This argument is superfluous if Σ is compact.

Assume first that Σ is non-compact. We fix $F \in C_c^\infty(\mathbb{R})$ equal to 1 near 0. We set:

$$\chi_n(y) = F(n^{-1}r(y)), \quad n \in \mathbb{N}^*,$$

where $r(y)$ is the approximation of the distance function given in Prop. 4.7. Since (Σ, h_0) is complete we have:

$$(4.7) \quad \begin{aligned} i) \quad & \chi_n \in C_c^\infty(\Sigma), \\ ii) \quad & s\text{-}\lim_{n \rightarrow \infty} \chi_n = \mathbb{1} \text{ on } \mathcal{H}_0^\pm, \\ iii) \quad & \|\nabla \chi_n\|_\infty \in O(n^{-1}). \end{aligned}$$

If Σ is compact we set $\chi_n(y) \equiv 1$.

From (4.5) we obtain that:

$$\begin{aligned} & (\chi_n^2 u^+ | K_0 u^+)_{\mathcal{H}_0^+} + (K_0 u^+ | \chi_n^2 u^+)_{\mathcal{H}_0^+} \\ &= 2(\partial_s \chi_n u^+ | \partial_s \chi_n u^+)_{\mathcal{H}_0^+} + (u^+ | (\chi_n^2 a_0(is) + a_0(is)^* \chi_n^2) u^+)_{\mathcal{H}_0^+} \\ & \quad - (\chi_n \gamma^+ u^+ | q \chi_n \gamma^+ u^+)_{\mathcal{S}}. \end{aligned}$$

Next, we write:

$$\begin{aligned} & \chi_n^2 a_0(is) + a_0(is)^* \chi_n^2 \\ &= \chi_n (a_0(is) + a_0(is)^*) \chi_n + \chi_n [\chi_n, a_0(is)] + [a_0(is)^*, \chi_n] \chi_n, \end{aligned}$$

which yields:

$$(4.8) \quad \begin{aligned} & (\chi_n^2 u^+ | K_0 u^+)_{\mathcal{H}_0^+} + (K_0 u^+ | \chi_n^2 u^+)_{\mathcal{H}_0^+} \\ &= 2(\partial_s \chi_n u^+ | \partial_s \chi_n u^+)_{\mathcal{H}_0^+} + (\chi_n u^+ | (a_0(is) + a_0(is)^*) \chi_n u^+)_{\mathcal{H}_0^+} \\ & \quad + (\chi_n u^+ | [\chi_n, a_0(is)] u^+)_{\mathcal{H}_0^+} + ([\chi_n, a_0(is)] u^+ | \chi_n u^+)_{\mathcal{H}_0^+} \\ & \quad - (\chi_n \gamma^+ u^+ | q \chi_n \gamma^+ u^+)_{\mathcal{S}}. \end{aligned}$$

The first line in (4.8) vanishes since $K_0 u^+ = 0$ in Ω^+ , the second is positive by (3.22). By Prop. 4.2 the third line is $O(n^{-1})$. Since $\gamma^+ u^+ = C_0^+ f$ we obtain:

$$(4.9) \quad (\chi_n C_0^+ f | q \chi_n C_0^+ f)_{\mathcal{S}} \geq -C n^{-1}.$$

To complete the proof of (2) we now use the identity (4.4) combined with reflection in s .

Let us set $iu(s, y) := u(-s, y)$ for $u \in \mathcal{H}_0$. Then since $a_0(is)^* = a_0(-is)$, and Ω is invariant under i we have

$$(4.10) \quad i : \text{Dom } K_0 \xrightarrow{\sim} \text{Dom } K_0^*, \quad K_0^* = i K_0 i.$$

Moreover if $I = \begin{pmatrix} \mathbb{1} & 0 \\ 0 & -\mathbb{1} \end{pmatrix}$ one has

$$(4.11) \quad \gamma^\mp \circ i = I \circ \gamma^\pm.$$

We take $u^+ = r^+ K_0^{-1} \gamma_0^* S_0 f$ as before and $v^+ = r^+ i K_0^{-1} \gamma_0^* S_0 g$ for $g \in C_c^\infty(\Sigma)^2$. Then from (4.4) we obtain

$$\begin{aligned} & (\chi_n^2 v^+ | K_0 u^+)_{\mathcal{H}_0^+} - (K_0^* v^+ | \chi_n^2 u^+)_{\mathcal{H}_0^+} \\ &= (v^+ | (\chi_n^2 a_0(is) - a_0(is) \chi_n^2) u^+)_{\mathcal{H}_0^+} + (\chi_n \gamma^+ v^+ | S_0 \chi_n \gamma^+ u^+)_{\mathcal{S}}. \end{aligned}$$

As above we write:

$$\chi_n^2 a_0(is) - a_0(is) \chi_n^2 = \chi_n [\chi_n, a_0(is)] + [\chi_n, a_0(is)] \chi_n,$$

which yields

$$\begin{aligned}
 (4.12) \quad & (\chi_n^2 v^+ | K_0 u^+)_{\mathcal{H}_0^+} - (K_0^* v^+ | \chi_n^2 u^+)_{\mathcal{H}_0^+} \\
 & = (\chi_n v^+ | [\chi_n, a_0(\text{is})] u^+)_{\mathcal{H}_0^+} + ([a_0(\text{is})]^*, \chi_n] v^+ | \chi_n u^+)_{\mathcal{H}_0^+} \\
 & \quad + (\chi_n \gamma^+ v^+ | S_0 \chi_n \gamma^+ u^+)_{\mathcal{S}}.
 \end{aligned}$$

We have $K_0 u^+ = 0$ in Ω^+ and by (4.10) $K_0^* v^+ = 0$ in Ω^+ so the first line in (4.12) vanishes. By Prop. 4.2 the second line is $O(n^{-1})$. By (4.11) we see that $\gamma^+ v^+ = I \gamma^- K_0^{-1} \gamma_0^* S_0 g = I C_0^- g$. Using also that $I^* S_0 = -q$ and $\gamma^+ u^+ = -C_0^+ f$, we obtain that the third line in (4.12) equals $(\chi_n C_0^- g | q \chi_n C_0^+ f)_{\mathcal{S}}$. Therefore we obtain

$$(\chi_n C_0^- g | q \chi_n C_0^+ f)_{\mathcal{S}} \in O(n^{-1}).$$

Taking $g = f$ this implies that

$$(4.13) \quad |(\chi_n C_0^- f | q \chi_n C_0^+ f)_{\mathcal{S}}| \in O(n^{-1})$$

We can now complete the proof of (2). We have for $f \in C_c^\infty(\Sigma)^2$ and n large enough

$$\begin{aligned}
 (f | q C_0^+ f)_{\mathcal{S}} & = (\chi_n^2 f | q C_0^+ f)_{\mathcal{S}} = (\chi_n f | q \chi_n C_0^+ f)_{\mathcal{S}} \\
 & = (\chi_n C_0^+ f | q \chi_n C_0^+ f)_{\mathcal{S}} + (\chi_n C_0^- f | q \chi_n C_0^+ f)_{\mathcal{S}} \\
 & \geq -C n^{-1},
 \end{aligned}$$

where we used (1) in the second line and (4.9), (4.13) in the third line. Letting $n \rightarrow +\infty$ we obtain (2). This completes the proof of the theorem. $\square$

4.4. Purity of ω_Ω . In this subsection we prove that the state ω_Ω is pure, using the characterization of pure states recalled in Prop. 2.1.

If Σ is compact, this follows immediately from the fact that $C_\Omega^\pm$ are projectors (note that $C_c^\infty(\Sigma) = C^\infty(\Sigma)$ then so $C_\Omega^\pm \circ C_\Omega^\pm$ is then well defined on $C_c^\infty(\Sigma)^2$). The fact that $C_\Omega^\pm$ are projectors in the compact case is well known, see e.g. [Gr, Prop. 11.7].

If Σ is not compact, we cannot a priori make sense of $C_\Omega^\pm \circ C_\Omega^\pm$, so an extra approximation argument is needed. In the proposition below we assume that Σ is not compact and we set $\psi_n = \chi_n^2$, where $\chi_n \in C_c^\infty(\Sigma)$ is the sequence of cutoff functions introduced in the proof of Thm. 4.5.

Proposition 4.8. *Let $f \in C_c^\infty(\Sigma)^2$. Then:*

$$\begin{aligned}
 (4.14) \quad & i) \quad \psi_n C_\Omega^+ f - C_\Omega^+ \psi_n C_\Omega^+ f \rightarrow 0, \\
 & ii) \quad \psi_n C_\Omega^+ \psi_n C_\Omega^+ f - C_\Omega^+ \psi_n C_\Omega^+ \psi_n C_\Omega^+ f \rightarrow 0,
 \end{aligned}$$

in $\mathcal{D}'(\Sigma)^2$ when $n \rightarrow \infty$.

Proof. By the same reasoning as in Step 1 in the proof of Thm. 4.5, it suffices to prove the analogue of (4.14) with C_Ω^+ replaced by $C_0^+ = -\gamma^+ K_0^{-1} \gamma^* S_0$.

Let us note that the identity (4.4) is of course still valid if $u \in \overline{C_c^\infty}(\Omega^\pm)$ and $v \in \overline{C^\infty}(\Omega^\pm)$. It is also valid if $u \in \overline{C_c^\infty}(\Omega^\pm)$ and $v \in \overline{H_{\text{loc}}^2}(\Omega^\pm)$, since all the terms in the identity are still well defined.

For $f \in C_c^\infty(\Sigma)^2$ we set

$$V_0^+ f := -r^+ K_0^{-1} \gamma^* S_0 f.$$

Let $w \in \overline{C_c^\infty}(\Omega^+)$ and

$$v = (K_0^{-1})^* e^+ w.$$

We know that $v \in H_0^1(\Omega)$ by Prop. 3.2, and $v \in H_{\text{loc}}^2(\Omega)$ using that $e^+ w \in L^2(\Omega)$ and elliptic regularity. For $u \in \overline{C_c^\infty}(\Omega^+)$ we obtain from (4.4):

$$(4.15) \quad (v|K_0 u)_{\mathcal{H}_0^+} - (K_0^* v|u)_{\mathcal{H}_0^+} = (\gamma^+ v|S_0 \gamma^+ u)_S = (\gamma v|S_0 \gamma^+ u)_S,$$

where in the last equality we use that $\gamma^\pm v = \gamma v$. In fact γv is well defined as an element of $H_{\text{loc}}^{3/2}(\Sigma) \oplus H_{\text{loc}}^{1/2}(\Sigma)$ since $v \in H_{\text{loc}}^2(\Omega)$. Next, we obtain:

$$(4.16) \quad \begin{aligned} (\gamma v|S_0 \gamma^+ u)_S &= (v|\gamma^* S_0 \gamma^+ u)_{\mathcal{H}_0} = ((K_0^{-1})^* e^+ w|\gamma^* S_0 \gamma^+ u)_{\mathcal{H}_0} \\ &= (e^+ w|K_0^{-1} \gamma^* S_0 \gamma^+ u)_{\mathcal{H}_0} = -(w|V_0^+ \gamma^+ u)_{\mathcal{H}_0^+}. \end{aligned}$$

From (4.15), (4.16) we obtain:

$$(4.17) \quad \begin{aligned} (w|u - V_0^+ \gamma^+ u)_{\mathcal{H}_0^+} &= ((K_0^{-1})^* e^+ w|K_0 u)_{\mathcal{H}_0^+}, \\ &= (v|K_0 u)_{\mathcal{H}_0^+}, \quad u, w \in \overline{C_c^\infty}(\Omega^+). \end{aligned}$$

We now fix $f \in C_c^\infty(\Sigma)^2$ and $u = V_0^+ f$. By Lemma A.1 in the appendix, we know that $u \in \overline{H_0^1}(\Omega^+) \cap \overline{C_c^\infty}(\Omega^+)$. We now apply (4.17) replacing u by $u_n = \psi_n u$, which belongs to $\overline{C_c^\infty}(\Omega^+)$.

Since $K_0 u = 0$ in Ω^+ , we have $K_0 \psi_n u = [K_0, \psi_n]u$ and since $\psi_n = \chi_n^2$:

$$[K_0, \psi_n] = [a_0(\text{is}), \psi_n] = \chi_n [a_0(\text{is}), \chi_n] + [a_0(\text{is}), \text{ch}_n] \chi_n.$$

By Prop. 4.2 we obtain:

$$\begin{aligned} |(v|[K_0, \psi_n]u)_{\mathcal{H}_0^+}| &\leq |(\chi_n v|[a_0(\text{is}), \chi_n]u)_{\mathcal{H}_0^+}| + |([a_0^*(\text{is}), \chi_n]v|\chi_n u)_{\mathcal{H}_0^+}| \\ &\leq Cn^{-1} \|v\|_{H^1(\Omega^+)} \|u\|_{H^1(\Omega^+)}. \end{aligned}$$

Using (4.17) this yields:

$$(4.18) \quad \begin{aligned} |(w|\psi_n u - V_0^+ \gamma^+ \psi_n u)_{\mathcal{H}_0^+}| &\leq Cn^{-1} \|v\|_{H^1(\Omega)} \|u\|_{H^1(\Omega^+)} \\ &\leq Cn^{-1} \|e^+ w\|_{H^{-1}(\Omega)} \|u\|_{H^1(\Omega^+)}. \end{aligned}$$

We claim that

$$(4.19) \quad \|e^+ w\|_{H^{-1}(\Omega)} \leq C \|w\|_{\overline{H_0^1}(\Omega^+)^*}.$$

Indeed, for $\tilde{g} \in C_c^\infty(\Omega)$ we have:

$$\begin{aligned} |(e^+ w|\tilde{g})_{\mathcal{H}_0}| &= |(w|r^+ \tilde{g})_{\mathcal{H}_0^+}| \\ &\leq C \|w\|_{\overline{H_0^1}(\Omega^+)^*} \|r^+ \tilde{g}\|_{H^1(\Omega^+)} \\ &\leq C \|w\|_{\overline{H_0^1}(\Omega^+)^*} \|\tilde{g}\|_{H^1(\Omega)}, \end{aligned}$$

which implies (4.19). Therefore we deduce from (4.18) by duality that if

$$r_{1,n} := \psi_n u - V_0^+ \gamma^+ \psi_n u,$$

we have

$$(4.20) \quad \|r_{1,n}\|_{H^1(\Omega)} \leq Cn^{-1} \|u\|_{H^1(\Omega^+)}.$$

Hence, $r_{1,n} \rightarrow 0$ in $\overline{H^1}(\Omega^+)$ as $n \rightarrow \infty$.

We now apply (4.17) once again replacing u by $v_n = \psi_n V_0^+ \gamma^+ \psi_n u$. We obtain since $K_0 V_0^+ \gamma^+ \psi_n u = 0$ in Ω^+ :

$$(w|v_n - V_0^+ \gamma^+ v_n)_{\mathcal{H}_0^+} = (w|[K_0, \psi_n] V_0^+ \gamma^+ \psi_n u)_{\mathcal{H}_0^+},$$

hence

$$|(w|v_n - V_0^+ \gamma^+ v_n)_{\mathcal{H}_0^+}| \leq C n^{-1} \|e^+ w\|_{H^{-1}(\Omega)} \|V_0^+ \gamma^+ \psi_n u\|_{H^1(\Omega^+)}.$$

By (4.20) we have

$$\|V_0^+ \gamma^+ \psi_n u\|_{H^1(\Omega^+)} \leq C \|\psi_n u\|_{H^1(\Omega^+)} + C n^{-1} \|u\|_{H^1(\Omega^+)} \leq C \|u\|_{H^1(\Omega^+)},$$

since $\|\nabla \psi_n\|_\infty \leq C$. Finally we obtain as before that:

$$(4.21) \quad r_{2,n} := \psi_n V_0^+ \gamma^+ \psi_n u - V_0^+ \gamma^+ \psi_n V_0^+ \gamma^+ \psi_n u \rightarrow 0 \text{ in } \overline{H^1}(\Omega^+),$$

as $n \rightarrow \infty$.

We note then that if $U \subseteq \Omega$ and $U^+ = U \cap \{s > 0\}$, we have $K_0 \psi_n u = 0$ in U^+ for $n \gg 1$, hence $K_0 r_{1,n} = K_0 r_{2,n} = 0$ in U^+ for $n \gg 1$. We can now use the argument of ‘partial hypoellipticity at the boundary’ (see e.g. [Gr, page 311]), which we now briefly explain.

We can introduce local coordinates on Σ near $y^0 \in \Sigma$, and map U to a neighborhood V of $(0, 0)$ in $\mathbb{R}^{1+d}$ for $d = \dim \Sigma$. We denote by $H^{m,\ell}(\mathbb{R}^{1+d})$ the space of $u \in \mathcal{S}'(\mathbb{R}^{1+d})$ such that $\langle D_x \rangle^m \langle D_y \rangle^\ell u \in L^2(\mathbb{R}^{1+d})$, and then using the coordinates we define the spaces $H_{\text{loc}}^{1+k,-k}(\Omega)$ and $\overline{H_{\text{loc}}^{1+k,-k}}(\Omega^+)$ (the definition depends on the choice of coordinates, but this is not important here). Then one deduces, using that $K_0 r_{i,n} = 0$ in U^+ that $r_{i,n} \rightarrow 0$ also in $\overline{H_{\text{loc}}^{1+k,-k}}(\Omega^+)$ for any $k \in \mathbb{N}$.

We can now safely apply the boundary value operator γ^+ and deduce from (4.20), (4.21) that:

$$\gamma^+ r_{i,n} \rightarrow 0 \text{ in } \mathcal{D}'(\Sigma)^2.$$

Using the definitions of u , $r_{i,n}$ and the fact that $C_0^+ = \gamma^+ V_0^+$ this yields:

$$\begin{aligned} \psi_n C_0^+ f - C_0^+ \psi_n C_0^+ f &\rightarrow 0, \\ \psi_n C_0^+ \psi_n C_0^+ f - C_0^+ \psi_n C_0^+ \psi_n C_0^+ f &\rightarrow 0, \end{aligned}$$

in $\mathcal{D}'(\Sigma)^2$ when $n \rightarrow \infty$, which entails the desired result. $\square$

Proposition 4.9. *The state ω_Ω is pure.*

Proof. By Prop. 2.1 it suffices to find, for each $f \in C_c^\infty(\Sigma)^2$, a sequence $f_n \in C_c^\infty(\Sigma)^2$ such that:

$$(4.22) \quad \lim_{n \rightarrow +\infty} \frac{|\bar{f} \cdot q f_n|^2}{f_n \cdot (\lambda^+ + \lambda^-) f_n} = \bar{f} \cdot (\lambda^+ + \lambda^-) f.$$

We take

$$f_n = \psi_n (C_\Omega^+ - C_\Omega^-) f,$$

and note first that

$$(4.23) \quad \bar{f} \cdot q f_n = \bar{f} \cdot q \psi_n (C_\Omega^+ - C_\Omega^-) f = \overline{\psi_n f} \cdot (\lambda^+ + \lambda^-) f = \bar{f} \cdot (\lambda^+ + \lambda^-) f$$

for $n \gg 1$, since f has compact support. It remains to compute the limit of the denominator in (4.22), which we will denote by I_n in the sequel. Since $C_\Omega^+ - C_\Omega^- = 2C_\Omega^+ - 1$ and $\lambda^+ + \lambda^- = q(2C_\Omega^+ - 1)$, we obtain:

$$I_n = \overline{\psi_n(2C_\Omega^+ - 1)f} \cdot q(2C_\Omega^+ - 1)\psi_n(2C_\Omega^+ - 1)f.$$

Next

$$(2C_\Omega^+ - 1)\psi_n(2C_\Omega^+ - 1) = 4C_\Omega^+\psi_nC_\Omega^+ - 2C_\Omega^+\psi_n - 2\psi_nC_\Omega^+ + \psi_n,$$

which yields:

$$\begin{aligned} I_n &= 8\overline{\psi_nC_\Omega^+f} \cdot qC_\Omega^+\psi_nC_\Omega^+f - 4\overline{\psi_nC_\Omega^+f} \cdot qC_\Omega^+\psi_nf \\ &\quad - 4\overline{\psi_nC_\Omega^+f} \cdot q\psi_nC_\Omega^+f + 2\overline{\psi_nC_\Omega^+f} \cdot q\psi_nf \\ &\quad - 4\overline{\psi_nf} \cdot qC_\Omega^+\psi_nC_\Omega^+f + 2\overline{\psi_nf} \cdot qC_\Omega^+\psi_nf \\ &\quad + 2\overline{\psi_nf} \cdot q\psi_nC_\Omega^+f - \overline{\psi_nf} \cdot q\psi_nf. \end{aligned}$$

Using that qC_Ω^+ is hermitian by Thm. 4.5 we obtain:

$$\begin{aligned} I_n &= 8\overline{f} \cdot qC_\Omega^+\psi_nC_\Omega^+\psi_nC_\Omega^+f - 4\overline{f} \cdot qC_\Omega^+\psi_nC_\Omega^+\psi_nf \\ &\quad - 4\overline{f} \cdot qC_\Omega^+\psi_n^2C_\Omega^+f + 2\overline{f} \cdot qC_\Omega^+\psi_n^2f \\ &\quad - 4\overline{f} \cdot q\psi_nC_\Omega^+\psi_nC_\Omega^+f + 2\overline{f} \cdot q\psi_nC_\Omega^+\psi_nf \\ &\quad + 2\overline{f} \cdot q\psi_n^2C_\Omega^+f - \overline{f} \cdot q\psi_n^2f. \end{aligned}$$

Next we use that f has compact support, hence for $n \gg 1$ we have:

$$\begin{aligned} I_n &= 8\overline{f} \cdot qC_\Omega^+\psi_nC_\Omega^+\psi_nC_\Omega^+f - 4\overline{f} \cdot qC_\Omega^+\psi_nC_\Omega^+f \\ &\quad - 4\overline{f} \cdot qC_\Omega^+\psi_n^2C_\Omega^+f + 2\overline{f} \cdot qC_\Omega^+f \\ &\quad - 4\overline{f} \cdot qC_\Omega^+\psi_nC_\Omega^+f + 2\overline{f} \cdot qC_\Omega^+f \\ &\quad + 2\overline{f} \cdot qC_\Omega^+f - \overline{f} \cdot qf. \end{aligned}$$

We now apply Prop. 4.8 ii) and obtain that:

$$\begin{aligned} I_n &= 8\overline{f} \cdot q\psi_nC_\Omega^+\psi_nC_\Omega^+f - 4\overline{f} \cdot q\psi_nC_\Omega^+f \\ &\quad - 4\overline{f} \cdot q\psi_n^2C_\Omega^+f + 2\overline{f} \cdot qC_\Omega^+f \\ &\quad - 4\overline{f} \cdot q\psi_nC_\Omega^+f + 2\overline{f} \cdot qC_\Omega^+f \\ &\quad + 2\overline{f} \cdot qC_\Omega^+f - \overline{f} \cdot qf + o(1). \end{aligned}$$

Using again that f has compact support we obtain:

$$\begin{aligned} I_n &= 8\overline{f} \cdot qC_\Omega^+\psi_nC_\Omega^+f - 8\overline{f} \cdot qC_\Omega^+f \\ &\quad + 2\overline{f} \cdot qC_\Omega^+f - \overline{f} \cdot qf + o(1) \\ &= \overline{f} \cdot q(2C_\Omega^+ - 1)f + o(1). \end{aligned}$$

Therefore

$$\lim_{n \rightarrow \infty} \overline{f_n} \cdot (\lambda^+ + \lambda^-)f_n = \overline{f} \cdot (\lambda^+ + \lambda^-)f,$$

which using (4.23) completes the proof of (4.22). $\square$

4.5. An example. For illustration let us consider the special case of an ultra-static metric

$$g = -dt^2 + h(y)dy^2,$$

where $(\Sigma, h(y)dy^2)$ is complete, and a constant mass term $V(x) = m^2 \geq 0$. Then,

$$P = \partial_t^2 + a, \quad K = -\partial_s^2 + a,$$

where $a = -\Delta_h + m^2$ is essentially self-adjoint in $L^2(\Sigma, |h|^{\frac{1}{2}}dy)$. We denote by $\epsilon \geq 0$ the square root of the closure of a .

As the set Ω we can take $] -T, T[\times \Sigma$ for $T > 0$. The closed operator K_Ω corresponds to Dirichlet boundary conditions at $s = \pm T$.

Let us denote by $\theta(s)$ the Heaviside step function.

We can easily compute K_Ω^{-1} , namely $K_\Omega^{-1}v = u - r$ where

$$u(s) = (2\epsilon)^{-1} \int_{-\infty}^{+\infty} \theta(s-s')e^{-(s-s')\epsilon} + \theta(s'-s)e^{(s-s')\epsilon} v(s') ds',$$

and

$$r(s) = (2\epsilon)^{-1} (e^{4T\epsilon} - 1)^{-1} (e^{(2T-s)\epsilon} v^+ - e^{s\epsilon} v^+ - e^{-s\epsilon} v^- + e^{(s+2T)\epsilon} v^-),$$

and

$$v^\pm = \int_{-T}^T e^{\pm s'} v(s') ds'.$$

A simple computation shows that the Calderón projector is

$$(4.24) \quad C_\Omega^+ = \frac{1}{2} \begin{pmatrix} 1 & \epsilon^{-1} \text{th}(T\epsilon) \\ \epsilon \coth(T\epsilon) & 1 \end{pmatrix}.$$

Note that the infrared singularity (occurring if $0 \notin \text{rs}(\epsilon)$) is completely ‘smoothed out’ by the Dirichlet boundary condition at $\{s = -T\} \cup \{s = T\}$.

Suppose now for simplicity that $\epsilon > 0$. In the limit when $T \rightarrow \infty$, the right hand side of (4.24) converges to a projection that corresponds to the *ground state* for P .

5. ANALYTIC HADAMARD PROPERTY

In this section we prove that the quasi-free state ω_Ω constructed in Thm. 4.5 is an analytic Hadamard state. We first recall well-known facts about the representation of distributions as sums of boundary values of holomorphic functions. We refer the reader to [H2, Chap. 3], [Ko, Sec. 3.4] for details.

5.1. Distributions as boundary values of holomorphic functions.

5.1.1. Notation. We first introduce some notation.

- In the sequel a cone of vertex 0 in $\mathbb{R}^n$ which is convex, open and proper will be simply called a *convex open cone*. If Γ, Γ' are two cones of vertex 0 in $\mathbb{R}^n$ we write $\Gamma' \subseteq \Gamma$ if $(\Gamma' \cap \mathbb{S}^{n-1}) \subseteq (\Gamma \cap \mathbb{S}^{n-1})$.
- If Γ is a convex open cone we denote by

$$\Gamma^\circ := \{\xi \in \mathbb{R}^n : \xi \cdot y \geq 0, \quad \forall y \in \Gamma\}$$

its polar. Γ° is a closed convex cone.

- Let $\Omega \subset \mathbb{R}^n$ be open and let $\Gamma \subset \mathbb{R}^n$ be a convex open cone. Then a domain $D \subset \mathbb{C}^n$ is called a *tuboid of profile $\Omega + i\Gamma$* if:

- (1) $D \subset \Omega + i\Gamma$,
- (2) for any $x_0 \in \Omega$ and any subcone $\Gamma' \subseteq \Gamma$ there exists a neighborhood Ω' of x_0 in Ω and $r > 0$ such that

$$\Omega' + i\{y \in \Gamma' : 0 < |y| \leq r\} \subset D.$$

- If $D \subset \mathbb{C}^n$ is open, we denote by $\mathcal{O}(D)$ the space of holomorphic functions in D .
- We write $F \in \mathcal{O}(\Omega + i\Gamma_0)$ if $F \in \mathcal{O}(D)$ for some tuboid D of profile $\Omega + i\Gamma$.
- If $F \in \mathcal{O}(D)$ for some tuboid D of profile $\Omega + i\Gamma$, we write $F \in \mathcal{O}_{\text{temp}}(\Omega + i\Gamma_0)$ and say that F is *temperate*, if for any $K \subseteq \Omega$, any subcone $\Gamma' \subseteq \Gamma$ and $r > 0$ such that $K + i\{y \in \Gamma' : 0 < |y| \leq r\} \subset D$, there exists $C, r > 0, N \in \mathbb{N}$ such that

$$(5.1) \quad |F(x + iy)| \leq C|y|^{-N}, \quad x \in K, \quad y \in \Gamma', \quad 0 < |y| \leq r.$$

5.1.2. *Boundary values of holomorphic functions.* If $F \in \mathcal{O}_{\text{temp}}(\Omega + i\Gamma_0)$ the limit

$$(5.2) \quad \lim_{\Gamma' \ni y \rightarrow 0} F(x + iy) = f(x) \text{ exists in } \mathcal{D}'(\Omega),$$

for any $\Gamma' \subseteq \Gamma$ and is denoted by $F(x + i\Gamma_0)$, (see e.g. [Ko, Thm. 3.6]).

If $\Gamma_1, \dots, \Gamma_N$ are convex open cones such that $\bigcup_1^N \Gamma_i^\circ = \mathbb{R}^n$ then any $u \in \mathcal{D}'(\Omega)$ can be written as

$$(5.3) \quad u(x) = \sum_{j=1}^N F_j(x + i\Gamma_j 0),$$

for some $F_j \in \mathcal{O}_{\text{temp}}(\Omega + i\Gamma_j 0)$. The non-uniqueness of the decomposition (5.3) is described by *Martineau's edge of the wedge theorem*, which states that

$$\sum_{j=1}^N F_j(x + i\Gamma_j 0) = 0 \text{ in } \mathcal{D}'(\Omega)$$

for $F_j \in \mathcal{O}_{\text{temp}}(\Omega + i\Gamma_j 0)$ iff there exist $H_{jk} \in \mathcal{O}_{\text{temp}}(\Omega + i\Gamma_{jk} 0)$ for $\Gamma_{jk} = (\Gamma_j + \Gamma_k)^{\text{conv}}$ (A^{conv} denotes the convex hull of A) such that

$$F_j = \sum_k H_{jk} \text{ in } \Omega + i\Gamma_j, \quad H_{jk} = -H_{kj} \text{ in } \Gamma_{jk},$$

see for example [Ko, Thm. 3.9].

5.2. **The analytic wave front set.** We now recall the definition of the *analytic wave front set* of a distribution on $\mathbb{R}^n$.

Definition 5.1. Let $u \in \mathcal{D}'(\Omega)$ for $\Omega \subset \mathbb{R}^n$ open and $(x^0, \xi^0) \in \Omega \times \mathbb{R}^n \setminus \{0\}$. Then (x^0, ξ^0) does not belong to the analytic wave front set $\text{WF}_a(u)$ if there exists $N \in \mathbb{N}$, a neighborhood Ω' of x^0 in Ω and convex open cones Γ_j , $1 \leq j \leq N$, such that

$$u(x) = \sum_{j=1}^N F_j(x + i\Gamma_j 0) \text{ over } \Omega',$$

for $F_j \in \mathcal{O}_{\text{temp}}(\Omega' + i\Gamma_j 0)$, $1 \leq j \leq N$, and F_j holomorphic near x^0 if $\xi^0 \in \Gamma_j^\circ$.

The equivalence of the above definition of the analytic wave front set with other ones, in particular with the one introduced by Hörmander (see e.g. [H2, Def. 8.4.3], has been proved by Bony in [B].

The analytic wave front set is covariant under analytic diffeomorphisms, which allows to extend its definition to distributions on a real analytic manifold in the usual way.

We will often work with open sets of the form $\Omega = I \times Y$ for $I \subset \mathbb{R}$ an open interval and $Y \subset \mathbb{R}^{n-1}$ open, writing $x \in \Omega$ as (t, y) . If $\Gamma =]0, +\infty[$, we will write simply $I \pm i0$ for the profiles $I \pm i\Gamma 0$. We denote by $\mathcal{O}_{\text{temp}}(I \pm i0; \mathcal{D}'(Y))$ the space of temperate $\mathcal{D}'(Y)$ -valued holomorphic functions on some tuboid D of profile $I \pm i0$. This means that for each $K \Subset I$ there exist $r > 0, N \in \mathbb{N}$ such that for each bounded set $B \subset \mathcal{D}(Y)$ there exist $C_B > 0$ such that

$$\sup_{\varphi \in B} |\langle u(z, \cdot), \varphi(\cdot) \rangle_Y| \leq C_B |\operatorname{Im} z|^{-N}, \quad \operatorname{Re} z \in K, \pm \operatorname{Im} z > 0, |\operatorname{Im} z| \leq r,$$

where $\langle \cdot, \cdot \rangle_Y$ is the duality bracket between $\mathcal{D}'(Y)$ and $\mathcal{D}(Y)$.

Let us set $\varphi_z(s) = (s - z)^{-1}$ for $z \in \mathbb{C} \setminus \mathbb{R}$. If $u \in \mathcal{D}'(\mathbb{R} \times \mathbb{R}^{n-1})$ has compact support, then

$$F(z, y) = \frac{1}{2i\pi} \langle \varphi_z(\cdot), F(\cdot, y) \rangle_{\mathbb{R}}$$

belongs to $\mathcal{O}_{\text{temp}}(\mathbb{R} \pm i0; \mathcal{D}'(\mathbb{R}^{n-1}))$ and

$$u(s, y) = F(s + i0, y) - F(s - i0, y),$$

where $F(s \pm i0, y) = \lim_{\epsilon \rightarrow 0^+} F(s + i\epsilon, y)$ in $\mathcal{D}'(\mathbb{R} \times \mathbb{R}^{n-1})$.

5.3. Proof of the analytic Hadamard property. Let us fix a neighborhood U of $\{0\} \times \Sigma$ in $\mathbb{R} \times \Sigma$, a neighborhood U' of Σ in M and

$$\chi : (U, -dt^2 + h_t(y)dy^2) \rightarrow (U', g)$$

the analytic isometric diffeomorphism given by the Gaussian normal coordinates to Σ in (M, g) . We recall that $\chi^*P = \partial_t^2 + r(t, y)\partial_t + a(t, y, \partial_y) = P(t, y, \partial_t, \partial_y)$. Since P has analytic coefficients, P extends holomorphically in $z = t + is$ to a neighborhood W of $\{0\} \times \Sigma$ in $\mathbb{C} \times \Sigma$. This holomorphic extension will be denoted by

$$P_z = P(z, y, \partial_z, \partial_y),$$

and $P(t, y, \partial_t, \partial_y)$ will be denoted by P_t . The Wick rotated operator $K = P(is, y, -i\partial_s, \partial_y)$, defined on a neighborhood V of $\{0\} \times \Sigma$ in $i\mathbb{R} \times \Sigma$, will henceforth be denoted by P_{is} .

We also fix an open set $\Omega \subset V$ as in Prop. 3.2 and recall that $C_{\Omega}^{\pm}$ are the associated Calderón projectors constructed in Sect. 4. Moreover for $f \in \mathcal{D}'(\Sigma)^2$ we denote by $U_{\Sigma}f \in \mathcal{D}'(U)$ the solution of the Cauchy problem:

$$\begin{cases} P_t u = 0 \text{ in } U \\ \rho_{\Sigma} u = f. \end{cases}$$

We will first prove in Prop. 5.3 a result of independent interest about a key property of $C_{\Omega}^{\pm}$. In the C^{∞} case (see [GW2, Thm. 3.12]) it is known that this property implies that ω is a C^{∞} Hadamard state.

We are indebted to Pierre Schapira for crucial help with the proof of Prop. 5.2, who also gave an extension of this result to the framework of $\mathcal{D}$ -modules in [Sch].

Proposition 5.2. *We have:*

$$\mathrm{WF}_a(U_\Sigma C_\Omega^\pm f) \subset \mathcal{N}^\pm \quad \forall f \in \mathcal{E}'(\Sigma)^2.$$

Proof. We only prove the proposition for C_Ω^+ , the proof for C_Ω^- being similar.

In the sequel we set $I =]-\delta, \delta[$ where $\delta > 0$ will be chosen small enough. We set

$$v := -K_\Omega^{-1} \gamma^* S f, \quad g := \gamma^+ v = C_\Omega^+ f, \quad u := U_\Sigma C_\Omega^+ f.$$

The proof will be split in several steps.

Step 1.

By the analytic propagation of singularities theorem (see [Kw, Thm. 3.3'] or [H4, Thm. 7.1]), it suffices to prove that $\mathrm{WF}_a(u) \subset \mathcal{N}^+$ over $I \times Y_1$ for a neighborhood $Y_1 \Subset \Sigma$ of some $y^0 \in \Sigma$. By a partition of unity argument, we can also assume that $\mathrm{supp} f \Subset Y$ where Y is an arbitrary open neighborhood of Y_1 . In fact since $P_{is}v = \gamma^* S f$ and P_{is} is an elliptic operator with analytic coefficients, we deduce from the Morrey-Nirenberg theorem (see e.g. [H1, Thm. 7.5.1]) that if $f = 0$ near Y_1 , then v is analytic near $\{0\} \times Y_1$ hence g is analytic near Y_1 . This implies that u is analytic near y^0 .

Another observation is that by finite propagation speed, if $g_1 = g$ near Y_1 , then $U_\Sigma g = U_\Sigma g_1$ near $I \times Y_1$. Therefore we can fix cutoff functions $\psi \in C_c^\infty(I)$, $\tilde{\psi} \in C_c^\infty(Y)$ with $\psi = 1$ near 0, $\tilde{\psi} = 1$ near Y_1 and replace v by χv for $\chi(s, y) = \psi(s)\tilde{\psi}(y)$ so that

$$(5.4) \quad \gamma^+ \chi v = \tilde{\psi} g.$$

Step 2.

Writing $z = t + is$ motivates the following notation that we will use in the sequel:

$$\begin{aligned} I^{r/l} &= I \cap \{\pm t > 0\}, \quad I^\pm = I \cap \{\pm s > 0\}, \\ D &= I \times iI, \quad D^\pm = I \times iI^\pm, \quad D^{r/l} = I^{r/l} \times iI. \end{aligned}$$

By Subsect. 5.1 we can write

$$(5.5) \quad \chi v(s, y) = v^r(is + 0, y) - v^l(is - 0, y),$$

where $v^{r/l}$ are the restrictions to $D^{r/l} \times Y_1$ of

$$F(z, y) = -\frac{1}{2i\pi} \langle \varphi_{-iz}(\cdot), \chi v(\cdot, y) \rangle_{\mathbb{R}}.$$

Since $P_{is}v = \gamma^* S f = \delta(s) \otimes h_0(y) + \delta'(s) \otimes h_1(y)$ for $h_0, h_1 \in \mathcal{E}'(\Sigma)$, we have

$$P_{is} \chi v = \delta(s) \otimes h_0(y) + \delta'(s) \otimes h_1(y) \text{ on } I \times Y_1.$$

Using that $\delta(s) = \frac{1}{2i\pi} \left(\frac{1}{s+i0} - \frac{1}{s-i0} \right)$, this implies that

$$P_z v^{r/l} = w \text{ in } D^{r/l} \times Y_1,$$

where

$$w(z, y) = \frac{1}{2\pi z} \otimes h_0(y) + \frac{1}{2i\pi z^2} \otimes h_1(y) + r(z, y),$$

and $r(z, y) \in \mathcal{O}(D; \mathcal{D}'(N_1))$. Note that $w \in \mathcal{O}_{\text{temp}}(D^+; \mathcal{D}'(Y_1))$. Let us now set (see also Fig. 1):

$$u^{r/l}(t, y) = v^{r/l}(t + i0, y)|_{I^{r/l}} \in \mathcal{D}'(I^{r/l} \times Y_1).$$

We have

$$P_t u^{r/l}(t, y) = P_z v^{r/l}(t + i0, y) = w(t + i0, y) \text{ in } I^{r/l} \times Y_1.$$

FIGURE 1. Relation between v , $v^{r/l}$ and $u^{r/l}$.

Since P_t is hyperbolic with respect to dt , we can extend $u^{r/l}$ to $\tilde{u}^{r/l} \in \mathcal{D}'(I \times Y_1)$ which solve

$$\begin{cases} P_t \tilde{u}^{r/l} = w(t + i0, y) \text{ in } I \times Y_2, \\ \tilde{u}^{r/l}(t, y) = u^{r/l}(t, y) \text{ in } I^{r/l} \times Y_2, \end{cases}$$

where $Y_2 \Subset Y_1$ is a neighborhood of y^0 in Σ . Since $w(t + i0, y)$ and $u^{r/l}(t, y)$ are boundary values of holomorphic functions from D^+ , we know (see for example [Ka, Thm. 4.3.10]) that

$$\text{WF}_a(w(t + i0, y)) \subset \{\tau \geq 0\} \text{ over } I \times Y_1,$$

$$\text{WF}_a(u^{r/l}(t, y)) \subset \{\tau \geq 0\} \text{ over } I^{r/l} \times Y_1.$$

By propagation of singularities (see [Kw, Thm. 3.3'] or [H4, Thm. 7.1]), this implies that

$$\text{WF}_a(\tilde{u}^{r/l}(t, y)) \subset \{\tau \geq 0\} \text{ over } I \times Y_2.$$

Let us denote by $\alpha = (\alpha_1, \dots, \alpha_{n-1})$ or $\beta = (\beta_1, \dots, \beta_{n-1})$ the elements of $\{-1, 1\}^{n-1} = A = B$ and by $\gamma = (\gamma_1, \dots, \gamma_{n-1})$ the elements of $C = A \sqcup B$, where $\sqcup$ denotes the disjoint union.

We set $\Delta_\gamma = \{y \in \mathbb{R}^{n-1} : y_j \gamma_j > 0\}$, and $\Gamma_\gamma =]0, +\infty[\times \Delta_\gamma$. Since the polar cones Γ_γ^o cover $\text{WF}_a(\tilde{u}^{r/l})$ over $I \times Y_2$, we can by [Ko, Thm. 3.9] write $\tilde{u}^{r/l}$ as

$$(5.6) \quad \tilde{u}^{r/l}(x) = \sum_{\alpha \in A} U_\alpha^{r/l}(x + i\Gamma_\alpha 0), \text{ over } I \times Y_2,$$

for $U_\alpha^{r/l} \in \mathcal{O}_{\text{temp}}((I \times Y_2) + i\Gamma_\alpha 0)$.

Similarly we have

$$(5.7) \quad u^{r/l}(x) = v^{r/l}(t + i0, y) = \sum_{\beta \in B} V_\beta^{r/l}(x + i\Gamma_\beta 0) \text{ over } I^{r/l} \times Y_2,$$

for $V_\beta^{r/l} \in \mathcal{O}_{\text{temp}}((I^{r/l} \times Y_2) + i\Gamma_\beta 0)$. By Martineau's edge of the wedge theorem, see [Ko, Thm. 3.9], we can find $H_{\gamma, \gamma'}^{r/l} \in \mathcal{O}_{\text{temp}}((I^{r/l} \times Y_2) + i\Gamma_{\gamma, \gamma'} 0)$, for $\Gamma_{\gamma, \gamma'} = (\Gamma_\gamma + \Gamma_{\gamma'})^{\text{conv}}$ such that $H_{\gamma', \gamma} = -H_{\gamma, \gamma'}$ and:

$$(5.8) \quad U_\alpha^{r/l} = \sum_{\gamma' \in C} H_{\alpha, \gamma'}^{r/l} \text{ on } (I^{r/l} \times Y_2) + i\Gamma_\alpha 0,$$

$$(5.9) \quad V_\beta^{r/l} = - \sum_{\gamma' \in C} H_{\beta, \gamma'}^{r/l} \text{ on } (I^{r/l} \times Y_2) + i\Gamma_\beta 0.$$

Let us set

$$\tilde{v}^{r/l}(z, y) = \sum_{\alpha \in A} U_\alpha^{r/l}(z, y + i\Delta_\alpha 0) \in \mathcal{O}_{\text{temp}}(D^+; \mathcal{D}'(Y_2)),$$

so that $\tilde{u}^{r/l}(t, y) = \tilde{v}^{r/l}(t + i0, y)$ by (5.6). We obtain that

$$\begin{aligned} \tilde{v}^{r/l}(z, y) &= \sum_{\alpha \in A, \gamma' \in C} H_{\alpha, \gamma'}^{r/l}(z, y + i\Delta_\alpha 0) \\ &= - \sum_{\beta' \in B, \alpha \in A} H_{\beta', \alpha}^{r/l}(z, y + i\Delta_\alpha 0) \\ &= - \sum_{\beta' \in B, \alpha \in A} H_{\beta', \alpha}^{r/l}(z, y + i\Delta_{\beta'} 0) \\ &= - \sum_{\beta' \in B, \gamma \in C} H_{\beta', \gamma}^{r/l}(z, y + i\Delta_{\beta'} 0) \\ &= v^{r/l}(z, y) \text{ in } D^+ \cap D^{r/l} \times Y_2. \end{aligned}$$

In the first line we use (5.8), in the second and fourth lines we use that $H_{\gamma, \gamma'} = -H_{\gamma', \gamma}$, in the third line the fact that $H_{\beta', \alpha} \in \mathcal{O}_{\text{temp}}((I^{r/l} \times Y_2) + i\Gamma_{\beta', \alpha} 0)$ and the property of boundary values of holomorphic functions recalled in 5.1.2, and in last line (5.9) and (5.7).

Summarizing we have:

$$(5.10) \quad \tilde{u}^{r/l}(t, y) = \tilde{v}^{r/l}(t + i0, y)$$

$$(5.11) \quad \begin{aligned} P_z \tilde{v}^{r/l}(z, y) &= w(z, y) \text{ in } D^+ \times Y_2, \\ \tilde{v}^{r/l}(z, y) &= v^{r/l}(z, y) \text{ in } (D^+ \cap D^{r/l}) \times Y_2. \end{aligned}$$

Step 3.

We now set

$$(5.12) \quad \tilde{v} = \tilde{v}^r - \tilde{v}^l \in \mathcal{O}_{\text{temp}}(D^+; \mathcal{D}'(Y_2)).$$

From (5.5), (5.11) we obtain

$$(5.13) \quad \begin{aligned} P_z \tilde{v} &= 0 \text{ in } D^+ \times Y_2, \\ \chi v(s, y) &= \tilde{v}(is, y) \text{ in } I^+ \times Y_2. \end{aligned}$$

Let

$$(5.14) \quad \tilde{u}(t, y) = \tilde{v}(t + i0, y) \in \mathcal{D}'(I \times Y_2).$$

From (5.13) we have $P_t \tilde{u}(t, y) = 0$ in $I \times Y_2$ and $\text{WF}_a(\tilde{u}) \subset \{\tau \geq 0\}$ over $I \times Y_2$. By microlocal ellipticity (see [SKK, Corr. 2.1.2] or [H4, Thm. 5.1]) this implies that $\text{WF}_a(\tilde{u}) \subset \mathcal{N}^+$ over $I \times Y_2$.

Step 4.

We claim that

$$(5.15) \quad \rho_\Sigma \tilde{u} = g \text{ on } Y_2.$$

Note that from (5.15) and finite propagation speed one can conclude that $\tilde{u} = U_\Sigma g$ near $I \times Y_3$ for $Y_3 \Subset Y_2$. Since $\text{WF}_a(\tilde{u}) \subset \mathcal{N}^+$ over $I \times Y_2$ we obtain the proposition, by the discussion in Step 1.

Therefore it remains to check (5.15). We recall that the cutoff functions $\tilde{\psi} \in C_c^\infty(Y)$, $\chi \in C_c^\infty(I \times Y)$ were introduced in Step 1 and that $\tilde{\psi}g = \gamma^+ \chi v$. Since $P_t \tilde{u} = 0$ in $I \times Y_2$ and $\{t = t_0\}$ are non-characteristic for P_t for t close to t_0 , we know that $\tilde{u} \in C^\infty(I; \mathcal{D}'(Y_2))$. For $\varphi \in \mathcal{D}(Y_2)$ we set

$$\begin{aligned} \tilde{u}_\varphi(t) &= \langle \tilde{u}(t, \cdot), \varphi(\cdot) \rangle_Y \in C^\infty(I), \\ \tilde{v}_\varphi(z) &= \langle \tilde{v}(z, \cdot), \varphi(\cdot) \rangle_Y \in \mathcal{O}_{\text{temp}}(D^+). \end{aligned}$$

By (5.14) we have

$$\tilde{u}_\varphi(t) = \lim_{\epsilon \rightarrow 0^+} \tilde{v}_\varphi(t + i\epsilon), \text{ in } \mathcal{D}'(I).$$

Since $\tilde{u}_\varphi \in C^\infty(I)$ we deduce then from [Ko, Thm. 3.6] that

$$\tilde{u}_\varphi(t) = \lim_{\epsilon \rightarrow 0^+} \tilde{v}_\varphi(t + i\epsilon) \text{ in } C^\infty(I).$$

In particular by (5.13) we have

$$\tilde{u}_\varphi(0) = \lim_{\epsilon \rightarrow 0^+} \langle \chi v(i\epsilon, \cdot), \varphi(\cdot) \rangle_Y = \langle \gamma_0^+ \chi v, \varphi \rangle_Y,$$

which by (5.4) implies that

$$\tilde{u}(0, y) = g_0(y) \text{ in } \mathcal{D}'(Y_2),$$

for $g = \begin{pmatrix} g_0 \\ g_1 \end{pmatrix}$. The same argument for $\partial_t \tilde{u}$ shows that $i^{-1} \partial_t \tilde{u}(0, y) = g_1(y)$ in $\mathcal{D}'(Y_2)$. This completes the proof of (5.15). $\square$

Proposition 5.3. *The state ω_Ω constructed in Thm. 4.5 is an analytic Hadamard state.*

Proof. We recall that the spacetime covariances of ω_Ω are given by:

$$\Lambda^\pm = (\rho_\Sigma \circ G)^* \circ \lambda^\pm \circ (\rho_\Sigma \circ G),$$

for $\lambda^\pm = q \circ C_\Omega^\pm$. Since the solution of the Cauchy problem

$$\begin{cases} P\phi = 0, \\ \rho_\Sigma \phi = f \end{cases}$$

is given by:

$$\phi = U_\Sigma f = G^* \circ \rho_\Sigma^* \circ qf,$$

we obtain

$$\Lambda^\pm = U_\Sigma \circ C_\Omega^\pm \circ (\rho_\Sigma \circ G).$$

Denoting by $x = (t, y)$ the variables in $M = \mathbb{R} \times \Sigma$ we obtain that the distribution kernel $\Lambda^\pm(x, x')$ solves the equation:

$$\begin{cases} P(x, \partial_x) \Lambda^\pm(x, x') = 0 \text{ in } M \times M, \\ \rho_\Sigma \Lambda^\pm(\cdot, x')(x) = r^\pm(y, x'), \end{cases}$$

where $r^\pm(y, x') \in \mathcal{D}'(\Sigma \times M)^2$ is the distribution kernel of $(C_\Omega^\pm \circ \rho \circ G)$.

We can now repeat verbatim the arguments in the proof of Prop. 5.2, replacing Σ by $\Sigma \times M$, the extra variable x' playing simply the role of a parameter. We obtain that

$$\text{WF}_a(\Lambda^\pm)' \subset \mathcal{N}^\pm \times T^*M.$$

Since $\Lambda^\pm$ is hermitian, this also implies that $\text{WF}_a(\Lambda^\pm)' \subset T^*M \times \mathcal{N}^\pm$ hence $\text{WF}_a(\Lambda^\pm)' \subset \mathcal{N}^\pm \times \mathcal{N}^\pm$. $\square$

APPENDIX A

A.1. An auxiliary lemma.

Lemma A.1. *Let $v \in \mathcal{E}'(\Omega)$ be equal to $\delta_s \otimes f$ or $\delta'_s \otimes f$ with $\pm s \leq 0$, $f \in C_c^\infty(\Sigma)$. Then*

$$(A.1) \quad r^\pm K_0^{-1} v \in \overline{H_0^1}(\Omega^\pm) \cap \overline{C^\infty}(\Omega^\pm).$$

Proof. Let $\chi, \chi_1, \chi_2 \in C_c^\infty(\Omega)$ be cutoff functions with $\chi = 1$ near $\text{supp } v$, $\chi_1 = 1$ near $\text{supp } \chi$ and $\chi_2 = 1$ near $\text{supp } \chi_1$. We then have:

$$(A.2) \quad \begin{aligned} r^\pm K_0^{-1} v &= r^\pm \chi_2 K_0^{-1} \chi v + r^\pm (1 - \chi_2) K_0^{-1} \chi v \\ &= r^\pm \chi_2 K_0^{-1} \chi v + r^\pm (1 - \chi_2) K_0^{-1} [\chi_1, K_0] K_0^{-1} \chi v. \end{aligned}$$

By assumption, $\chi v \in H_c^{-2}(\Omega)$. By elliptic regularity $K_0^{-1} : H_c^s(\Omega) \rightarrow H_{\text{loc}}^{s+2}(\Omega)$, therefore $[\chi_1, K_0] K_0^{-1} \chi v \in H_c^{-1}(\Omega)$. By the definition of K_0^{-1} via quadratic forms, we know that $K_0^{-1} : H^{-1}(\Omega) \rightarrow H_0^1(\Omega)$, hence

$$r^\pm (1 - \chi_2) K_0^{-1} [\chi_1, K_0] K_0^{-1} \chi v \in \overline{H_0^1}(\Omega^\pm).$$

On the other hand, by elliptic regularity we know that $(1 - \chi_2) K_0^{-1} [\chi_1, K_0]$ is infinitely smoothing, hence

$$r^\pm (1 - \chi_2) K_0^{-1} [\chi_1, K_0] K_0^{-1} \chi v \in \overline{C^\infty}(\Omega^\pm).$$

Let us now consider the first term in the second line of (A.2). By Lemma 3.3 we know that $\chi_2 K_0^{-1} \chi = \chi_2 Q \chi + R_{-\infty}$, where $Q \in \Psi_c^{-2}(\Omega)$ and $R_{-\infty}$ has a smooth, compactly supported kernel in $\Omega \times \Omega$. The term

$$r^\pm R_{-\infty} v$$

obviously belongs to $\overline{C_c^\infty}(\Omega^\pm)$. Next, from [Gr, Thm. 10.25] we know that $\chi_2 Q \chi(\delta_s \otimes \cdot)$ and $\chi_2 Q \chi(\delta'_s \otimes \cdot)$ are *Poisson operators*. In particular by [Gr, Thm. 10.29], $\chi_2 Q \chi(\delta_s \otimes \cdot)$ and $\chi_2 Q \chi(\delta'_s \otimes \cdot)$ map $C_c^\infty(\Sigma)^2$ into $\overline{C_c^\infty}(\Omega^\pm)$ continuously. Therefore,

$$r^\pm \chi_2 K_0^{-1} \chi v \in \overline{C_c^\infty}(\Omega^\pm).$$

In conclusion we get (A.1). $\square$
